Our study area was the estuary of the Yarra River, which drains part of southern Victoria, Australia, and includes the city of Melbourne with 1,200,000 inhabitants in its catchment. The estuary is 22 km long and highly stratified[8], but not oxygen deficient. The river discharges into Port Phillip Bay, a large embayment with only a small outlet to Bass Strait. The survey was made in late winter at a time of high river flow (22 August 1978). Water samples were filtered through prewashed Gelman 0.45 μm membrane filters, stored in glass bottles at 4 °C in the dark, and analysed within a month of collection. Previous storage experiments showed that no measurable changes in iodate or iodide occurred in water stored in these conditions.

Iodate in seawater, and in estuarine waters of salinity >2‰ was determined directly by differential pulse polarography (DPP)[9,10]. A 20-ml aliquot of the water sample was pipetted into a polarographic cell, EDTA solution was added to suppress the zinc wave, and the solution deoxygenated by bubbling argon. A Metrohm E500 series Polarecord with a dropping mercury electrode, platinum wire counter electrode, and Ag/AgCl/M KCl reference electrode, was used. Concentration of iodate was determined by the method of standard additions. Iodide was determined in a separate aliquot of the sample by oxidation of iodide to iodate by addition of chlorine water[11], evaluation of the new level of iodate by the polarographic method, and calculation of iodide by difference. We found ultraviolet (UV) irradiation[10] unsuitable for iodide determination, as it produced peroxide that interfered and also gave iodate from 'organo'-iodine compounds in estuarine waters. No interfering species were produced by chlorine water in the experimental conditions used. In river water, the iodate-plus-iodide concentration could not be found by simple addition of chlorine water, as the large amount of dissolved organic matter interfered with the determination. A modified procedure was developed, in which a 50-ml aliquot of river water was treated with sodium hydroxide and chlorine water, then evaporated to dryness under an infrared lamp. The residue was redissolved in 10 ml of doubly distilled, deionised water, this solution treated with chlorine water, and sodium formate solution added. The resulting solution was filtered to remove coagulated organic matter and made up to 25 ml with water. Iodate-plus-iodide was then determined on a 20-ml aliquot after addition of EDTA. Analysis of water of salinity 5‰ by both procedures yielded results that were not significantly different, indicating that the more complex treatment did not convert any further iodine to iodate.

Replicate analyses of a bulk estuarine sample of salinity 19.4‰, collected at an earlier date, gave 7.9 μg l^{-1} I as iodate with a coefficient of variation of 6.7%; 53.4 μg l^{-1} I as iodate-plus-iodide with a coefficient of variation of 3.2%; and by difference, 45.5 μg l^{-1} I as iodide with a coefficient of variation of 9.9%. The limit of detection of iodate is largely dependent on establishment of the baseline of the polarograms, but taking two standard deviations at the 7.9 μg l^{-1} level it is about 1.0 μg l^{-1} I. Salinity was measured using an AutoLab 602 salinometer calibrated using IAPSO standard seawater.

Results from the Yarra River estuary (Fig. 1) indicate that both iodide and iodate show conservative behaviour. The river water contained 23 μg l^{-1} I as iodide, and <1.0 μg l^{-1} as iodate. The seawater contained 28 μg l^{-1} I as iodate, and 36 μg l^{-1} as iodide, as the average of five samples with a mean salinity of 34.0‰. 'Iodine', as iodide-plus-iodate, determined after oxidation with chlorine water, was 23 μg l^{-1} in the Yarra river water which is within the range of 2.2 to 42.4 μg l^{-1} reported for iodine in other rivers of the world[12]. The dominant form of iodine in rocks and soils is iodide. This is likely to be the case in the Yarra drainage basin, and apparently no conversion to iodate occurs in the transit from source mineral to the river. 'Iodine' in seawater of 34‰ salinity from Port Phillip Bay at 64 μg l^{-1} I is higher than seawater values reported by Truesdale[13], but comparable with the average values of Barkley and Thompson[3] and Wong[14].

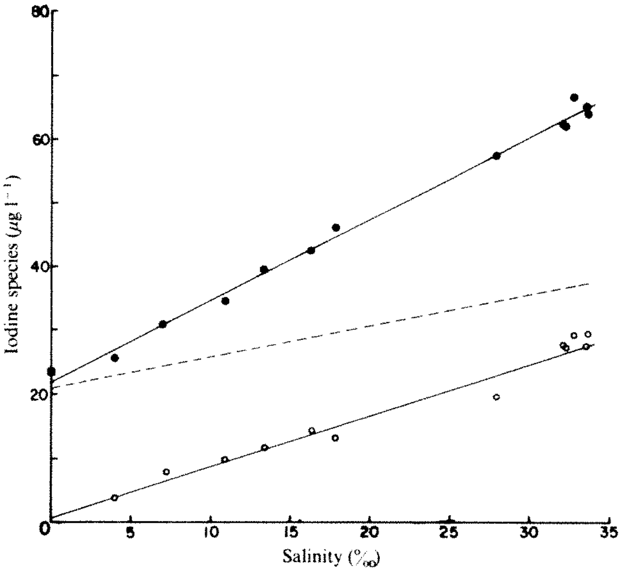

Fig. 1 Relationship between salinity and concentration of iodate (○) and iodate-plus-iodide (●). Lines of best fit are shown, and the dashed line represents the iodide concentration determined by difference. The concentration of iodate-plus-iodide in river water (■) was determined by a procedure different from that used for estuarine waters.

The present study indicates that there is no measurable conversion of the iodide of river water to iodate within the Yarra River estuary, and that the iodate in the estuary comes from the seawater. Consequently, it seems that oxidation of iodide to the thermodynamically stable iodate occurs in the seawater outside the estuaries. Two mechanisms, which are known to effect oxidation of iodide to iodate occur through UV irradiation, and by biological activity of algae. We have used UV irradiation for conversion of iodide to iodate as an analytical technique, and found that quantitative conversion of iodide to iodate required ~3 h exposure to a 1,200 W mercury lamp at a distance of 6 cm. Sunlight would be expected to affect only the surface water, and then at a very slow rate. The effects of algae on iodide and iodate in seawater have been reported. Sugawara and Terada[15] found that a diatom culture in seawater containing 16 μg l^{-1} iodide converted 3 μg l^{-1} iodide to iodate in four weeks. Truesdale[13] found that some *Chlorophycae*, cultured in seawater containing 50 μg l^{-1} interconverted not more than 5 μg l^{-1} in an unspecified time.

Although we did not observe any apparent reaction of iodide or iodate in the estuary, we did detect the presence of a third iodine form. When we exposed waters of intermediate salinity to UV irradiation for 4 h before addition of chlorine water, we observed an increase in the iodate detectable by DPP compared with that found after oxidation using chlorine water alone. Our experiments with 2-iodo-benzoic acid in the conditions used in analysis of estuarine waters showed that iodide in this compound was not converted to iodate by treatment with chlorine water, whereas UV irradiation followed by treatment with chlorine

0028-0836/79/0277—0468$01.00

water gave quantitative recovery of the organo–iodine as iodate determined by DPP. The estuarine water of salinity 13.4‰ contained 27.9 μg l^{-1} I as iodide, 11.6 μg l^{-1} as iodate, and a further 7.0 μg l^{-1} released after UV irradiation and treatment with chlorine water. The increase is probably the result of decomposition of organo–iodine compounds by the UV irradiation, and 15% of the total iodine was present in this estuarine water as 'organo'–iodine. The seawater of 34‰ did not yield additional iodate when UV irradiated before chlorination. Organo–iodine has been reported in seawater by Truesdale[16] but there are no previous reports of iodine speciation in estuarine or river waters.

The results of Truesdale[13] show a relatively constant 'total' iodine in seawaters, with a decrease in iodide and increase in iodate progressing from Menai Strait, through the Irish Sea, to North Atlantic Ocean waters. He suggests that iodate-reducing substances introduced to the sea by terrestrial run-off might explain these observations.

On the basis of our evidence, variations of iodide to iodate ratio might also be largely explained as the result of oxidation of iodide delivered by rivers to the oceans. The production of iodate seems to be thermodynamically favoured, but limited by the slow rate of conversion, with a reported half life of tens of years[17]. This is too slow for it to be observed in the Yarra River estuary, where residence time is only days. Hence conversion of iodide to iodate must occur in the ocean, possibly under the influence of enzyme systems.

Effect of glacial ice melting on the Antarctic Surface Water

MOST glacial ice melting occurs below the sea surface and in regions where ice shelves and icebergs are concentrated, as along the Antarctic coastline. We show here that this melting can significantly affect the Antarctic Surface Water (AASW) chemistry and biology only for glacial ice constituents are greatly depleted (for example, salt, oxygen-18) or enhanced (for example, ammonia?) relative to the ocean. The surface water nutrient (nitrate, phosphate, silicate) budget is controlled primarily by the upwelling of deep water. Melting beneath the Ross Ice Shelf results in the northwards lateral movement of near-freezing water to the continental shelf break. Basal melting of icebergs and smaller ice shelves may contribute to the temperature minimum at the base of the AASW.

The volume of meltwater produced annually from melting Antarctic glacial ice will be three orders of magnitude less than the AASW reservoir, which extends from 50 to 200 m depths over the 20 × 10^6 km^2 area south of the Polar Front (Antarctic convergence). For an Antarctic ice cap in an equilibrium state, the average annual volume of glacial ice lost must equal the 0.15 m yr^{-1} net accumulation over the 14 × 10^6 km^2 area of Antarctica[1]. We assume relatively little ablation[2]. Net deep melting of 0.30 m yr^{-1} (refs 3, 4) beneath the large ice shelves, which comprise less than 11% of the ice cap[4,5], would account for no more than a quarter of the 2.1 × 10^3 km^3 wastage. The remaining ice will melt at shallower levels, within or near the base of AASW from icebergs, ice streams, small ice shelves and from the northern edges of the major ice shelves.

Parker *et al.*[6] have suggested that nitrogen-laden ice originating on the Antarctic continent provides, on melting, a major contribution (7% yr^{-1}) to the nitrogen budget of the 50 m epipelagic zone of the Antarctic oceans. Since then Biggs has shown[7] that Parker *et al.* used incorrect nitrate (NO_3–N) values, and he has recomputed the nitrate input from continental ice as 0.02% of that in the AASW, assuming a surface mean of 12 μg-atoms l^{-1}. However, there are significant differences between the nitrate observations reported by various expeditions in the Antarctic oceans (Fig. 4 in ref. 8). Our AASW nitrate measurements[8,9] and those of the Geosecs expeditions[10] range from 15–30 μg-atoms l^{-1}, with a mean around 22 μg-atoms l^{-1}. With this higher nitrate mean, and a reservoir thickness closer to 100 m than to 50 m, the net nitrate input from glacial ice would be 0.005% of that already in the AASW.

The Parker *et al.*[6] nitrate mean of 19.57 μg l^{-1} (1.4 μg-atoms l^{-1}) is an order of magnitude less than the AASW nitrate concentration, so iceberg melting would cause a slight nitrate decrease locally in the AASW rather than an enrichment as claimed. Subsequently, Parker *et al.*[11] reported nitrate values as high as 37 μg-atoms l^{-1} in additional ice samples, but they do not indicate whether their nitrate mean has increased or decreased from 1.4 μg-atoms l^{-1}. We have made nitrogen measurements on glacial ice recovered from the sea near a green iceberg[12] and on an ice core sample from 66 m below the surface of the Ross Ice Shelf at 82°22.5′S, 168°37.5′W. The nitrate assay was 3.9 μg-atoms l^{-1} in the iceberg, and 1.1 μg-atoms l^{-1} in the ice core, consistent with the earlier Parker *et al.* data.

Nitrate, phosphate and silicate are the nutrients commonly measured in seawater. These nutrients are present in abundance in the AASW south of the Polar Front and are not generally believed to limit phytoplankton growth. If other compounds such as ammonia (NH_4–N) are limiting to the rate of primary production[7], then melting glacial ice may be an important factor, locally. Our ammonia value for the ice shelf core sample (2.4 μg-atoms l^{-1}) is similar to the Parker *et al.* mean (1 μg-atoms l^{-1}). Both measurements are an order of magnitude greater than surface water ammonia concentrations reported for the Ross Sea (< 0.1–0.3 μg-atoms l^{-1}) (ref. 7). The ammonia levels of aliquots drawn from the atypical green iceberg sample ranged from 25 to 33 μg-atoms l^{-1}, slightly above the range for South Pole ice core samples[6]. The green iceberg sample also contained quartz grains and metallic particles (J. Anderson, personal communication), fibres, algal cells, and an organic nitrogen level of 241.6 μg-atoms l^{-1}. A thin section showed it to be derived from a valley glacier (A. Gow, personal communication).

Upwelled deep water is the primary source of nitrate, phosphate and silicate in the AASW. Beneath the AASW, nitrate values are uniformly above 30 μg-atoms l^{-1} (refs 9, 10). This deeper water upwells into the surface layers, replacing waters that mix and sink as Antarctic Bottom Water and Antarctic Intermediate Water. The upwelling rate, based upon temperature, salinity and oxygen-18 budgets, has been estimated to be 60 × 10^6 m^3 s^{-1} (refs 13, 14), corresponding to a nitrate input to the AASW of 8 × 10^8 tonnes yr^{-1}. This is four orders of magnitude greater than the meltwater contribution of 3 × 10^4 tonnes yr^{-1}, derived from the Parker *et al.* mean nitrate for glacial ice and the assumption of an equilibrium ice cap. Nitrate

0028–0836/79/0277—0469$01.00

enrichment of 18% in the euphotic zone of a glaciated Arctic fiord was first attributed to rock flour[15] and later to upwelling[16].

Most iceberg melting occurs below the sea surface in the predominantly above-freezing environment that exists there during all seasons. Holdsworth and others have shown that the amount of downwarping of sea ice attached or frozen to icebergs in d'Iberville Fiord, NWT, Canada, may be accounted for by continuous melting of the submerged portions of the glacier ice throughout the year. Thus, there may be no sharp seasonal glacial ice melting peaks coincident with phytoplankton blooms[6].

Several associations have been reported between glacial ice and the biological community. Bottom scouring by icebergs affects bottom dwellers in several ways[17]. Links have been noted between icebergs or shelf ice and microflora[18], diatoms[19], Arctic terns[20], seals in the Arctic[17] and leopard seals in the Antarctic[21]. We have observed Antarctic petrels, snow petrels and Adelie penguins on and in the vicinity of icebergs. Glacial ice contains some 3–8% (by volume) compressed air bubbles[22] that may influence mixing processes when the ice melts. The 'sizzling' noise that accompanies the bubble pressure release "should be detectable by sonar . . . out to distances of 50–100 miles against the ambient sea background"[23]. If plankton levels are higher near icebergs, then the noise of that melting ice could well attract higher species.

There is evidence that melting glacial ice may influence vertical processes in the surface layers. Neshyba[24] has pointed out the potential importance of iceberg-induced upwelling on the oceanography of the Weddell Sea, and Foldvik and Kvinge[25] have described the possible thermohaline upwelling of near-freezing water near ice shelves. Few oceanographic observations have been made in the vicinity of Antarctic icebergs. The anomalously high subsurface salinities and temperatures recently reported near a large Antarctic iceberg[26] may be an artefact of the instrument or calibration. In the Ross Sea we have observed brash or pack ice surrounding an iceberg (see also Fig. 24 in ref. 27) but separated from it by a ring of open water. This may result from upwelling along the walls, wave and swell interaction, or differential motion between iceberg and smaller pieces of ice with shallower draft. Upwelling was considered responsible for muddy ice-free water at the sea faces of glaciers in Greenland[28]. Josberger[29] reported field measurements of melt-driven upwelling adjacent to an Arctic iceberg, and modelled both upwelling and downwelling in the laboratory. Several of his vertical temperature–depth profiles suggest additional effects at 50–70 m.

In another laboratory experiment[30] meltwater was observed to mix and spread laterally away from ice blocks inserted into salt-stratified water. Huppert and Turner noted the production of a "series of tilted convecting layers which grow out into the environment". They found that "a considerable portion of the melt water can be fed into the environment close to the level at which it is produced and very little, if any, rises to the surface".

We have measured the large scale lateral spreading of water (Fig. 1) that has been cooled by melting at the base of the Ross Ice Shelf[3]. This Ice Shelf Water[31] extends northwards to at least the continental shelf break. A similar water mass is found on the continental shelf in the Weddell Sea[32] and adjacent to the Amery Ice Shelf[33]. Ice Shelf Water temperatures are as low as the *in situ* freezing point; salinity ranges from 34.4 to 34.75‰, but does not usually form a local minimum within the vertical halocline. Ice Shelf Water with potential temperature below −2.0 °C has been observed in the Ross Sea at depths from 225 to 525 m. We have hypothesised[3] that the main source of heat for melting at the base of the Ross Ice Shelf is provided by an intermediate-depth warmer layer, derived from the Circumpolar Deep Water. Pettersson[34] seems to have modelled several of the thermohaline features we observed north of the Ross Ice Shelf.

Similar to flow away from the Ross Ice Shelf (Fig. 1) and ice in the laboratory[30], most meltwater from icebergs may spread laterally rather than upwell along the sides. Typical tabular Antarctic icebergs will have initial drafts approximating the depths below sea level of the terminal faces of the ice shelves. A study of 407 Antarctic icebergs[35] showed a mean freeboard of 40 m, corresponding to a subsurface draft of 182 m. Mean widths for icebergs observed with Landsat imagery in one Antarctic sector were 0.4 km on the edge of the pack ice and 0.7 km in the pack ice[36]. For icebergs with dimensions larger than about 0.7 km, basal area will exceed wall area. The base should then be the primary wastage surface[34] and this surface will frequently be near the lower levels of the AASW. Alternatively, if calving as a result of wave-induced melting and mechanical erosion were the primary disintegration process[37], most melting would take place nearer the sea surface. We have often observed the calving of brash and growler-sized pieces

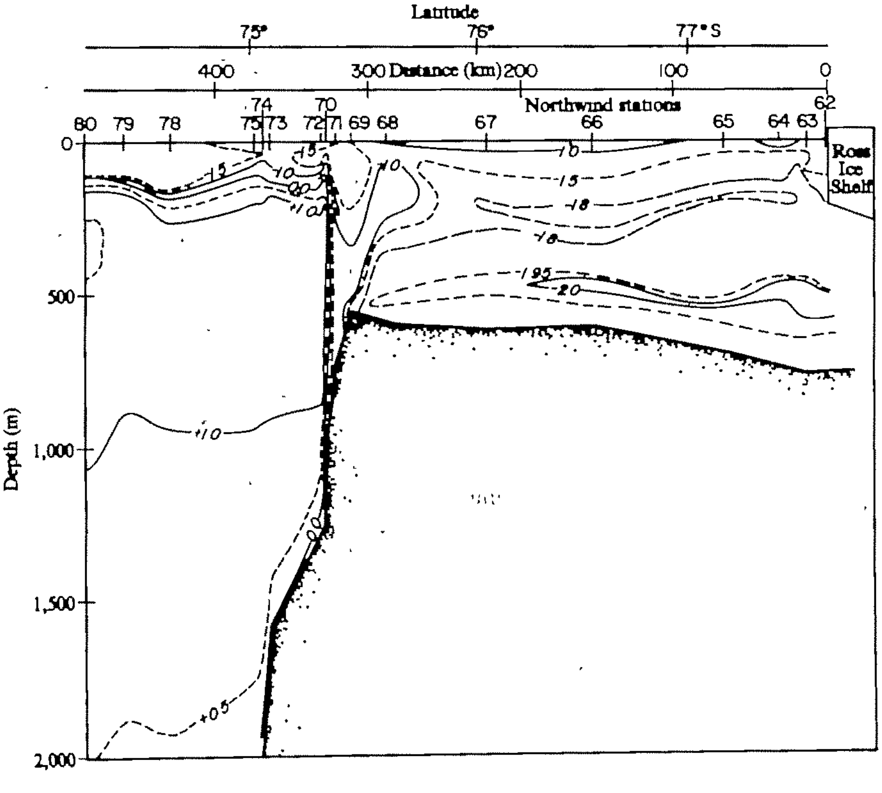

Fig. 1 Potential temperature profile from USCGC Northwind stations taken in December 1976 (ref. 46). The section extends about 500 km north-east of station 62, which was next to the Ross Ice Shelf at 178° E longitude. A layer of ice shelf water[31] ($\theta < -1.95$ °C), that results from melting beneath the ice shelf, reaches the continental shelf break. A shallower layer of ice shelf water ($\theta < -1.8$ °C) also extends north from the ice shelf at Antarctic surface water depths. An intermediate depth warmer layer ($\theta > 1.8$ °C), better developed on the east–central continental shelf, provides the major heat flux for melting of the glacial ice[3].

from the northern face of the Ross Ice Shelf, but note that much of the region populated by Antarctic icebergs and ice shelves is covered by sea ice for most of the year, which should limit wave-induced erosion.

The temperature minimum at the base of the Antarctic Surface Water is generally attributed to vertical winter mixing, with subsequent capping by a warm summer mixed layer[38]. However, the large latent heat exchange (80 cal g^{-1}) at the base of melting icebergs and subsequent lateral mixing of the meltwater could also contribute to this feature. Where the temperature minimum is shallow, as in the Weddell Gyre, the impact of iceberg melting may extend well below the AASW. The step-structure in the centre of the Weddell Gyre that Huppert and Turner attribute to "systematic injection of meltwater at intermediate depths" is best developed just below the temperature minimum in their Fig. 1*b* (ref. 30). Over the AASW region south of the Antarctic Convergence, the heat exchanged annually in melting glacial ice should be sufficient to lower by 1 °C the temperature of a layer 7.5 m thick. While the upwelling rate used above corresponds to an AASW residence time of only one year, decreasing this rate[39] would allow to a greater influence of iceberg melting on the AASW. An order of magnitude more heat will be taken up by the summer melting of pack ice than by the annual melting of glacial ice, but the melting pack ice will primarily involve only the top few metres of seawater. That meltwater will have a stabilising effect on the water column, and the associated latent heat flux will be more than offset by incoming radiation[40].

The environmental impact of melting icebergs will not be evenly distributed in space and time. Iceberg tracks will be influenced by currents, oceanic fronts, winds, pack ice, bottom topography, and by the location and productivity of drainage areas. From our observations and published accounts[35,36,42,43] of iceberg distribution and movement, we would expect the maximum impact from melting icebergs to occur in the Antarctic coastal zone. There a cold and fresh water mass, V-shaped in cross-section[44] is frequently observed over the Antarctic continental slope. It extends to depths of several hundred metres and apparently defines the deeper portion of the surface westwards coastal current[45]. Its low temperature and low salinity[44,46] probably result in part from melting glacial ice. It may be a source reservoir for both the AASW temperature minimum and the fresh component of Antarctic Bottom Water.

North of the continent, icebergs frequently appear in clusters and are likely to travel preferred routes. The gigantic Trolltunga iceberg that has been tracked by satellite for 11 years (Fig. 23 in ref. 27) may provide evidence for the association of icebergs with convergent frontal zones. Once Trolltunga entered the northern Scotia Sea it seems to have tracked the southern boundary of the Polar Front, possibly grounding as it crossed the North Scotia Ridge. Moving parallel to the bottom contours, it then executed two reversals in an east–west direction, a characteristic feature of the front in that region[47]. To the extent that icebergs are associated with frontal zones[48], the meltwater may contribute to lower surface salinities sometimes observed there (Fig. 4*b* in ref. 49).

This work has been supported by the NSF, Division of Polar Programs grants 76-81240, 76-11872 (Ross Ice Shelf Project) and 77-22209 to Columbia University. We thank the officers and crews of USCGC Northwind and Ara Islas Orcadas, and J. Ardai, P. McDonald, M. Rodman, and A. Roy for help. The Ross Ice Shelf core sample was provided by C. Langway.

Isolation and characterisation of a bipotential haematopoietic cell line

VARIOUS cell lines have been used to study the regulation of proliferation and differentiation, and events occurring during mutagenesis and carcinogenesis. These include 'normal' cell lines which, however, frequently show chromosome changes, especially aneuploidy, and where normality is based essentially on the nontumorigenic capacity of the cells. Whether such cells retain the ability to fulfil their genetically programmed functional state *in vivo* has not been determined. Moreover, although studies using transformed, tumorigenic cells (Friend leukaemia[1], myeloid leukaemia[2] and neuroblastoma[3]) have given useful information on some of the factors involved in differentiation, the fact that the cells are tumorigenic indicates that caution must be exercised in the interpretation of results. We report that we have now isolated and cloned an autonomous haematopoietic cell line where the cells have a diploid complement of chromosomes, are non-tumorigenic and bipotential (can be induced to differentiate *in vivo* into two distinct haematopoietic lineages), and which in appropriate circumstances protect mice from potentially lethal radiation.

The cell line was isolated from a long-term culture[4] of (C57BL/6 × DBA/2)F_1 female bone marrow cells, which had been infected with NB-tropic, polycythaemia-inducing Friend

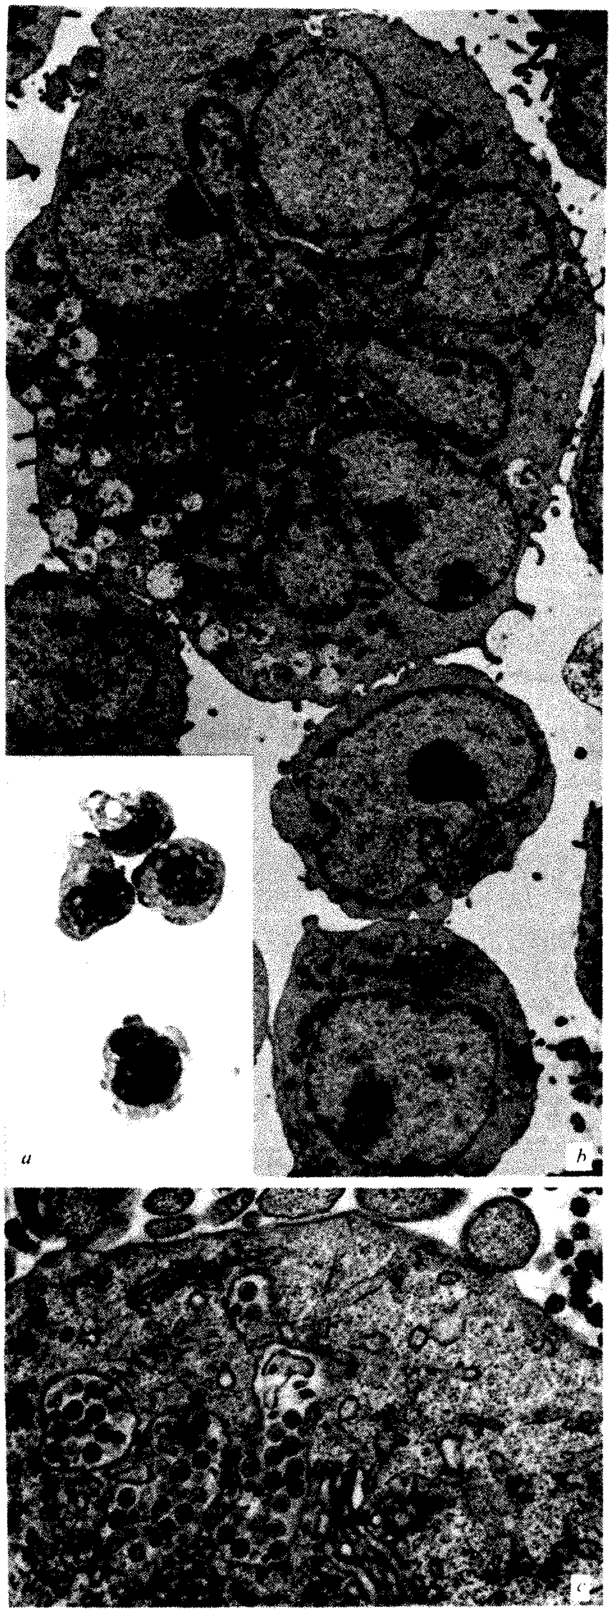

Fig. 1 *a*, Cultured 416B cells stained with May–Grunwald Giemsa. Note large nuclear:cytoplasmic ratio, vacuolated cytoplasm (×750) *b*, Section through a pellet of 416B cells after glutaraldehyde–osmium fixation, showing the size variation of cultured cells. Three small round cells are apparent (corresponding to *a*), with smooth nuclear profiles and undifferentiated cytoplasmic morphology. The large cell (perhaps a megakaryocyte precursor) is characterised by size, dense mitochondrial population and extensive nuclear segmentation (×4,500). *c*, Detail of the cytoplasm of an undifferentiated cell, showing vacuoles containing intracellular immature virus particles, lacking the external coat. Extracellular virus particles are also apparent (×26,000).

leukaemia virus (FLV)[5]. Table 1 shows the essential features of these cultures. For the first 5–6 weeks, the virus-infected cultures behaved similarly to the controls, with both groups demonstrating extensive production of granulocytes (all stages of maturation) and maintenance of haematopoietic stem cells (CFU-S)[6] and granulocyte precursor cells (CFU-C)[7,8]. The CFU-S formed spleen colonies containing all haematopoietic elements (erythroid, granulocytic and megakaryocytic). Subsequently, haematopoiesis in the control cultures decreased, and eventually only phagocytic mononuclear cells remained. In the virus-infected cultures, on the other hand, there was a sustained granulopoiesis (with a marked shift towards the production of immature forms) and a massive increase in CFU-S. However, as previously reported[5], such CFU-S show limited differentiation capacity, producing spleen colonies containing only granulocytes and megakaryocytes. No erythropoiesis was observed. It is particularly significant that throughout the culture period, injection of the culture cells or cell-free supernatants into neonatal or adult syngeneic mice did not result in the development of leukaemia at >1 yr post-inoculation. In this respect, therefore, the cultures differ from our previously reported results[5] where we showed that following infection of genetically susceptible marrow cultures with FLV complex, both the helper (LLV) and the 'defective' (SFFV) viral components replicated, resulting in a maintenance of the erythroleukaemia-inducing capacity of the virus. In the present experiment, although the LLV component is detectable (with weekly titres

Table 1 Characteristics of normal and Friend leukaemia virus-treated long-term marrow cultures

Weeks cultured	Cell count $\times 10^5$	Morphology B	EG	LG	Mono	Total CFU-S	Total CFU-C
1	14.8(11.3)*	4(0)	8(4)	58(62)	30(32)	703(358)	ND(4,380)
5	20.4(54.0)	35(27)	29(30)	23(36)	10(8)	340(1,120)	5,050(18,000)
10	20.8(10.2)	10(3)	70(8)	5(60)	12(28)	1,730(211)	2,670(ND)
14	21.6(6.6)	30(8)	60(10)	1(6)	5(76)	32,940†(0)	ND(328)
16	31.8(1.0)	16(0)	66(0)	1(2)	15(98)	136,740†(0)	ND(0)
18	33.6(3.0)	25(0)	70(0)	0(0)	4(100)	500,000†(0)	ND(0)
20	50.0(1.8)	40(0)	55(0)	0(0)	5(100)	250,000†(0)	>50,000†(ND)

Cultures were established as previously described[5]. The cells were tested weekly for CFU-S and/or CFU-C and smears made for morphological examination. B, Blast cells, EG, promyelocytes and myelocytes; LG, metamyelocytes and polymorphonuclear cells; Mono, phagocytic mononuclear cells; ND, not done.

* Control (normal) values are in parentheses.

† Restricted differentiation capacity.

ranging from 2×10^4 to 8×10^5 plaque-forming units per ml (ref. 9), the erythroleukaemogenic ability (the SFFV component) has been lost. The precise reasons for this are unclear (and now under investigation), but the end result was that we were able to isolate a cell line with unique characteristics.

After 20 weeks of culture (Table 1), aliquots of cells were transferred to fresh culture flasks. After several days, cell proliferation of a nonadherent population was observed and further sub-culture was possible. The cells were designated 416B and samples of these early isolates were cryopreserved. Morphologically, the cells are heterogeneous: the majority are undifferentiated blast cells and 'promyelocytic' cells (Fig. 1*a*), with occasional larger cells with lobed nuclei. Ultrastructural analysis shows that the majority of cells are undifferentiated, have a large nuclear : cytoplasm ratio, smooth nuclear profiles and limited condensed chromatin (Fig. 1*b*). A minor proportion of cells shows some nuclear segmentation characteristic of immature granulocytes. The larger multi-lobed cells strongly resemble megakaryocytes (Fig. 1*b*). Many cells show cytoplasmic and extracellular forms resembling C-type virus particles (Fig. 1*c*). The population doubling time of the cells is 38–44 h. Karyotype analysis showed that about 95% of the cells possess a diploid chromosome complement, the remaining cells being true tetraploid or octaploid cells; this supports the proposal that the larger cells are developing megakaryocytes.

The colony-forming ability of the cells *in vitro* is shown in Table 2. Cells were plated in the presence or absence of heart conditioned medium[10] as a source of colony-stimulating activity (CSA) which is essential for the growth of normal bone marrow granulocyte precursor cells (CFU-C)[11]. At low cell concentration, colony formation occurred only in the presence of CSA-containing medium, but at higher cell concentrations, CSA was not necessary. Thus, at high cell densities, the cells apparently produce growth-promoting factors; it is not known whether such factors are equivalent to CSA. The colonies consisted of loosely dispersed cells, reminiscent of 'macrophage' colonies[11], and in this respect differed from the typical compact colonies generally formed by leukaemic murine cells. Morphological analysis of the colony cells showed them to be similar to the parent population, with no obvious differentiation. Individual colonies were isolated from soft agar; all such isolates readily proliferated and produced permanently growing cell lines with characteristics identical to the original parental population, including the cell heterogeneity previously mentioned. We have tried to induce *in vitro* differentiation and maturation of the cells, using a variety of agents that promote differentiation of certain granulocytic or erythroid leukaemia cell lines[1,2]. These included purified L-cell CSA, purified erythropoietin, dimethyl sulphoxide, 5-bromodeoxyuridine, dexamethasone, and conditioned medium obtained from long-term cultures of normal mouse bone marrow cells. None of these reagents has so far induced morphological differentiation.

The cells do, however, form macroscopically visible colonies in the spleens of irradiated mice (Table 2 and Fig. 2*a*); although the number produced varied widely, on all occasions the colonies contained only granulocytes and megakaryocytes at all stages of maturation (Fig. 2*b*). Smears taken from the bone marrow also showed this limited differentiation pattern (Fig. 3*a*, *b*). There was no evidence of erythropoiesis or lymphopoiesis. Thus, in the appropriate *in vivo* environment, the cultured cells undergo apparently normal development. However, mice reconstituted with the cultured cells rapidly became anaemic due to defective erythropoiesis, and death occurred 11–20 d post-irradiation. In an attempt to prolong survival, the reconstituted mice were given weekly intraperitoneal injections of 0.5 ml packed red blood cells; 30% of these mice survived for longer than 7 weeks. After 2 weeks only granulocytic and occasional megakaryocytic cells were found. Surface marker analysis failed to demonstrate the presence of Thy-1 antigen or surface immunoglobulin-positive lymphoid cells.

Table 2 *In vitro* and *in vivo* colony formation by 416B cells

In vitro			*In vivo*			
Cells plated (3 ml)	CSA Present	Absent	Cells injected	Spleen colonies I	II	III
10^3	15±2	0	5×10^2	20±1	0	0
10^4	182±21	0	10^3	28±3	0	0
10^5	>1,000	>1,000	5×10^3	Confluent	1	0
5×10^5	Confluent colonies	Confluent colonies	10^4	Confluent	2.5	1
			10^5	Confluent	25.3	18.5

In *in vitro* experiments, the cells were plated in 3 ml Fischers medium supplemented with 20% horse serum (Flow) and antibiotics, in 0.3% agar. CSA was added as a 20% mouse heart conditioned medium[10]. Results are the mean and standard error of three experiments. In *in vivo* experiments, the cells were injected into mice previously exposed to 800 rads. The animals were killed 8–9 d later and the spleens removed and fixed in Bouin's solution. Individual colonies were counted with a dissecting microscope. Experiments I, II and III were carried out 2, 5 and 10 months, respectively, after establishing the cell line.

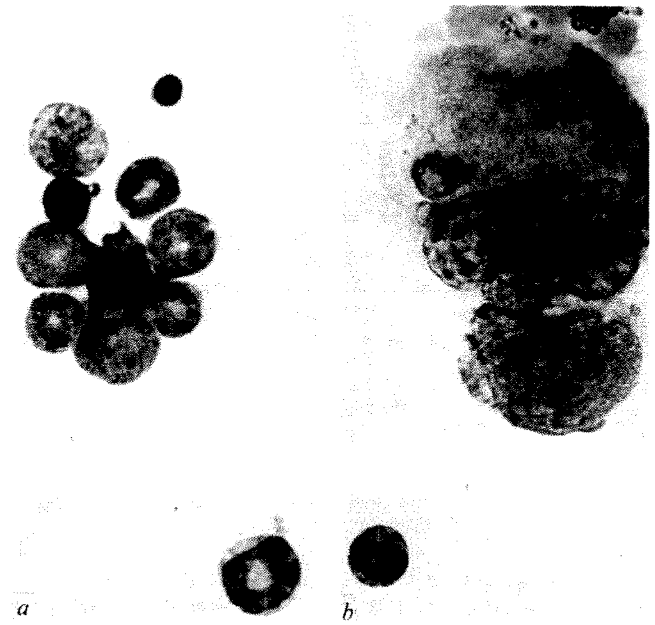

Fig. 3 *a*, Bone marrow taken from mice 2 weeks after injection of 416B cells; note extensive granulopiesis (×750). *b*, As *a*, showing megakaryopoiesis (×750).

At 6 weeks post-reconstitution, spleen and bone marrow cellularity had recovered to near normal values. Within the spleen the granulocytes were the major population, although 14% of the cells were Thy-1-positive lymphocytes; B cells were absent. Granulocytes were also found in the bone marrow and at this time limited erythropoiesis was apparent. Karyotyping of the cells showed that approximately 50% of the spleen cells were of donor origin, whereas in the bone marrow, all the cells were of host origin. This presumably represents re-emergence of a surviving host stem cell population[12] to provide erythropoiesis and T-lymphopoiesis. This finding is not surprising, as the elegant experiments of Micklem *et al.*[13,14] showed that stem cells differ in their 'competitiveness'. For example, when irradiated mice are reconstituted with a mixture of stem cells derived from the peripheral blood and bone marrow, both populations can initiate haematopoiesis, and presumably both can contribute to the 'short-term' survival of these animals. Within a few weeks, however, the number of 'blood-derived' cells declines and the haematopoietic system is reconstituted with marrow-derived stem cells[14]. That system seems analogous to the one reported here and similar mechanisms may be in operation. Indeed, there is increasing evidence to indicate that there is a hierarchy of stem cells (CFU-S) which differ in self-renewal capacity[12-15] and perhaps in their ability to differentiate. The cell line described here may have arisen from a cell with restricted differentiation potential. The relatively few long-term survivors in our reconstitution system may be related to the delayed onset of lymphopoiesis and consequent severe immunodeficiency in these animals.

Several questions arise. (1) Can the differentiation 'block' be overcome *in vitro*? (2) Is there a sub-population of normal stem cells *in vivo* which has similarly restricted differentiation potential, or is the restriction imposed on the cells following infection with leukaemia virus? (3) Will antisera raised against the cells determine new haematopoietic or differentiation linked antigens? (4) Can the cells be induced to undergo leukaemic transformation and, if so, do specific chromosomal changes[16] occur? The answers to these points will give us valuable information on the nature of haematopoietic cell differentiation and transformation.

A specific helper factor which enhances the cytotoxic response to a syngeneic tumour

IMMUNE RESPONSES are regulated at least in part by a complex system of cellular interactions which result in the specific enhancement or suppression of the reaction to a given antigen. In many situations soluble 'factors' seem to be able to replace these cells, although whether they actually do so *in vivo* remains unknown. Specific suppressor factors have been demonstrated to influence a variety of humoral and cell-mediated immune responses. Specific helper factors which augment antibody production have been studied extensively[1-3], but analogous factors active in cell-mediated immunity have not yet been documented. Soluble factors which enhance the generation of cytotoxicity have been reported by several workers[4-8] but none of these has been demonstrated to be antigen specific. We report here the isolation of a helper factor which specifically enhances the generation of cytotoxic cells in a syngeneic mouse tumour system.

We have shown previously that cells from spleen or thymus of mice bearing the P815 mastocytoma, or extracts from these organs, can specifically suppress the generation *in vitro* of cells cytotoxic to P815 (refs 9–11). These results are in basic agreement with those of Fujimoto *et al.*[12] and Green *et al.*[13], who examined the influence of suppressor cells or factor on the *in vivo* growth of methylcholanthrene-induced tumours. In either assay system the activity measured is a net value which could comprise components of both help and suppression. Fractionation of our crude thymus suppressor factor by isoelectric focusing or by gel filtration indicated that there were fractions showing net enhancement of cytotoxicity suggesting the presence of both a helper and a suppressor factor in the same extract. In subsequent work aimed at the isolation of a helper factor, fractions of spleen extracts separated by gel filtration were used.

Figure 1 shows the effluent profile of extracts from normal or 8-d tumour-bearer spleens separated on G150 Sephadex. The

0028–0836/79/0277—0474$01.00

fractions were added to cultures containing normal DBA/2 spleen cells together with mitomycin-C-treated P815 cells as antigen. After 5 d the cells were collected and tested for cytotoxicity against P815 in an overnight ^{51}Cr-release assay. Results from cultures containing fractions from the tumour bearers were compared with those from cultures containing an equivalent concentration of normal fractions. Only fractions II and III showed significant differences between the tumour and normal extract. Fractions prepared from extracts of spleens taken at various times after tumour injection indicated that suppressive activity, if present, was in fraction II, whereas enhancing activity appeared in fraction III, indicating that the two activities could be at least partially separated on the basis of size (these data will be presented elsewhere). For subsequent work on the purification of a helper factor, fraction III from 8-d tumour-bearer spleens was used.

Anti-P815 cytotoxicity generated in cultures containing tumour-bearer fraction III (TIII) at concentrations between 0.1 and 0.05 spleen equivalents was consistently enhanced (five experiments, data not shown), as compared with controls containing equivalent amounts of normal factor III (NIII). Further purification of the factor was affected by absorbing NIII or TIII on to columns of P815 membrane fragments linked to Sepharose. Bound material was eluted in mildly dissociating conditions with 2 M salt. As shown in Fig. 2*a*, the eluted material derived from TIII was markedly enhancing at a concentration of 0.05 spleen equivalents. Equivalent results were obtained with 0.005 spleen equivalents, but at lower concentrations than this the helper activity was diluted out (data not shown). However, the control eluate derived from NIII did not influence the response at any concentration tested. The data in Fig. 2*a* show that the purified helper factor increased the cytotoxicity about fourfold in terms of cytotoxic units. The specificity of the factor was tested by adding it to parallel cultures containing mitomycin-treated L1210 rather than P815 as antigen. Neither fraction had any effect on the generation of anti-L1210 cytotoxicity (Fig. 2*b*). Similarly, the P815 helper factor did not enhance anti-H-2^d killing generated in cultures of C57BL/6 spleen cells with irradiated DBA/2 spleen cells (data not shown). We have shown previously that cytotoxicity in the syngeneic system is T-cell dependent (and probably T-cell mediated), in that treatment of the effector population with anti Thy-1 antiserum and complement before the 18-h abolishes killing[10]. This was also true of the enhanced cytotoxicity generated in the presence of P815 helper factor, suggesting that the mechanism of killing was not altered.

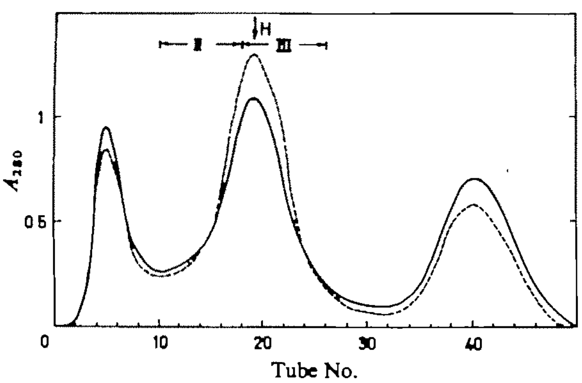

Fig. 1 Fractionation of spleen extracts on Sephadex G150. Extracts were prepared by the technique previously used for thymus tissue[11]. Spleens were taken from 8–12-week-old normal (broken line) or tumour-bearing (solid line) female DBA/2 mice. The tumour bearers were injected 8 d before death with 2×10^3 P815 mastocytoma cells in the right flank. At the time of death, the tumour was growing as an easily palpable confined mass at the site of injection. There was no evidence of metastasised tumour cells in the spleen by microscopic examination. Five spleens suspended in a small volume of phosphate-buffered saline (PBS) were frozen and thawed, homogenised in a conical glass tissue grinder, sonicated twice for 60 s on ice, centrifuged at 60,000*g* for 60 min at 4 °C, and the supernatant was immediately applied to the Sephadex column. The column was eluted with borate saline, *p*H 8.3, collecting 4-ml fractions which were pooled as indicated. Mouse haemoglobin eluted near the peak of the second peak as indicated by arrow H.

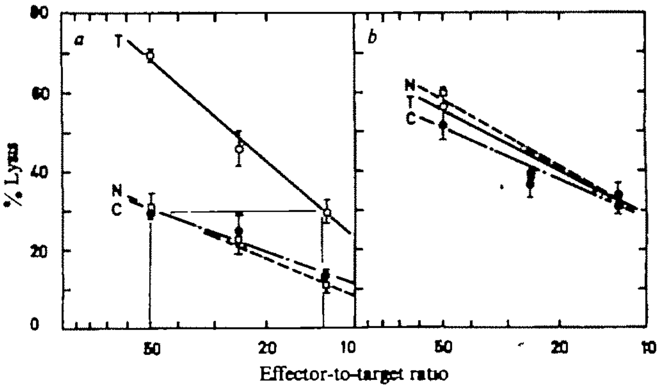

Fig. 2 The effect of P815 membrane column-purified helper factor on the *in vitro* generation of cytotoxicity to syngeneic P815 (*a*) and L1210 (*b*) tumour cells. 5×10^6 normal DBA/2 spleen cells were cultured with 5×10^5 mitomycin-C-treated P815 or L1210 cells in 2.5 ml of RPMI 1640 in 24 well Linbro plates (No. 76–033–05). Cultures contained 10% fetal calf serum, 10 mM HEPES, 2×10^{-5} M 2-mercaptoethanol, with or without 0.05 spleen equivalents of test fractions. After incubation for 5 d at 37 °C the cells were collected and set up in a standard 18-h ^{51}Cr-release assay[9] against ^{51}Cr-labelled P815 or L1210. The results show the averages and standard deviations of triplicate cultures. The P815 membrane Sepharose column was prepared as previously described[11] by linking a sonicate of P815 membranes obtained by hypotonic lysis to Sepharose 4B activated with cyanogen bromide. Unreacted groups were blocked with ethanolamine and the absorbent was washed with 0.1 M HCl and 2 M NaCl before use. Fractions were stirred for 15 min at either 4 °C or room temperature with the absorbent. The absorbent was then poured into a small column, washed with PBS until the A_{280} of the eluate was <0.01 and then eluted with 2 column volumes of 2 M NaCl. The A_{280} of the eluted material was in all cases <0.01. It was stored at −70 °C. Concentration is quoted as spleen equivalents based on the volume of original spleen homogenate, corrected for the change in volume following gel and affinity chromatography. Values for the eluted fractions are maximums based on the assumption that all the activity in the Sephadex fraction was recovered. Identical results were obtained using 0.005 spleen equivalents of purified factor. It can be seen in (*a*) that for an equivalent level of cytotoxicity, for example, 30%, about a quarter of the number of cells from helper-induced cultures were required as compared to controls, indicating an approximately fourfold increase in cytolytic units. ○, □, Cultures containing eluted fractions derived from TIII or NIII, respectively; ●, control cultures without added factor.

Helper factors in other systems[2,14,15] have been shown to be coded for by the I region of the major histocompatibility complex (MHC). Figure 3 indicates that this is also true for the P815 helper factor. In this experiment, the factor was incubated overnight with the antiserum; any immune complexes as well as residual free mouse immunoglobulin (Ig) were then removed on an anti-mouse Ig immunoadsorbent column. The capacity of the column was sufficient to bind twice the amount in the samples. Thus, free antibody, which might influence the response, was not added to the cultures.

The anti Ia used here was prepared by immunising B10 mice repeatedly with B10D2 splenocytes. To render this serum specific for the Ia region of the H-2^d MHC, it was absorbed exhaustively against P815 cells until it was no longer cytotoxic for these targets in the presence of rabbit complement. The properties of this absorbed antiserum are outlined elsewhere[16]. It can be seen that helper activity was absorbed by this antiserum. As controls, either anti H-2^k or normal B10 serum absorbed with P815 (results not shown) were used. The purpose

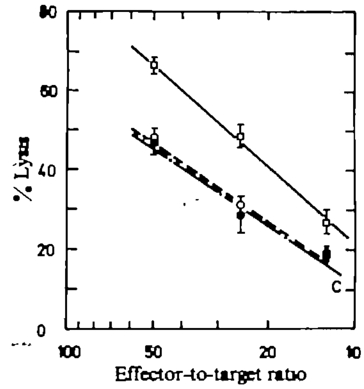

Fig. 3 The effect of anti-Ia antiserum absorption on the activity of P815 membrane column-purified helper factor. The ability of anti-Ia^d to remove helper activity from purified helper factor TIIIe was tested by an immunoadsorbent assay described previously[11]. Anti-Ia^d antiserum was prepared from B10 anti-B10.D2 antiserum by absorption with P815 as outlined elsewhere[16]. The control antiserum was B10.D2 anti-B10.BR. The antiserum and factor were incubated overnight at 4 °C and then passed over an immunoadsorbent column of goat anti-mouse Ig. This material was then added to cultures at a concentration of 0.01 spleen equivalents. Identical results were obtained in a second experiment using P815-absorbed normal B10 serum as the control. □, anti H–2^k; ○, anti Ia^d; ●, control.

of these controls was to show that the loss of helper activity was not due to some inhibitory effect of anti-H–2 antiserum or to the presence of P815 antigen which might combine with the helper factor. In neither case did the control antiserum remove activity. The results of this experiment show that the helper factor bears I-region-coded markers but does not possess constant-region determinants of mouse Ig. They do not exclude the possibility that the factor also has K^d or D^d determinants.

The properties of the P815 helper factor are consistent with those of helper factors active in the antibody response. It binds antigen, is not a conventional antibody molecule, and seems to be I-region coded. Its molecular weight is about 50,000 by gel filtration. Preliminary results from SDS-polyacrylamide gel electrophoresis of iodinated factor in reducing conditions indicate that it is a monomer of MW 65,000. We know of no other reports of antigen-specific helper factors active in the generation of cytotoxic T cells . There is, however, recent evidence of a requirement for specific helper cells in the generation of killer T cells in allogeneic systems.[17] As well as providing an additional way to study the mechanisms that regulate the generation of cytotoxic cells, the factor described here may offer a means of altering the course of tumour growth *in vivo*.

Cytolytic and proliferative activity of a permanent T killer cell line

ATTEMPTS to establish lymphocyte cell lines with specific cytotoxic activity by viral transformation of cytotoxic thymus-derived lymphocytes (T killer cells) have been unsuccessful in many laboratories. Screening of thymic lymphomas for specific cytolytic activity and attempts to hybridise thymic lymphomas with T killer cells have also been unsuccessful. During these studies it has become apparent, however, that alloreactive T cells derived from a primary mixed lymphocyte culture can be maintained in tissue culture for several months or even years, provided these cells are periodically stimulated with irradiated allogeneic spleen cells[1,2]. Many of these cell lines, although retaining specific proliferative activity, tend to lose their cytolytic activity after about 6–12 months[1–4]. This, of course, makes these cell lines less useful for studying the receptor specificity, cytolytic activity or clinical usefulness of T killer cells. Here I report the successful establishment in tissue culture of a cell line which has retained both specific proliferative and cytotoxic activity for almost three years in continuous culture.

Table 1 Cytolytic activity of C C3 11 · 75

	Target*	H–2	Attacker to target ratio	PHA†	% Cytotoxicity‡

* Spleen cells (10^6 per ml) were cultured for 3 d in the presence of 10 μg ml^{-1} bacterial lipopolysaccharide, collected and labelled with ^{51}Cr (ref. 2).

† PHA concentration was 5 μg ml^{-1} in the assay.

‡ The following equation was used to express cytotoxicity:

$$\% \text{ cytotoxicity} = \frac{(\text{experimental } ^{51}\text{Cr release} - \text{spontaneous } ^{51}\text{Cr release})}{(\text{maximal } ^{51}\text{Cr release} - \text{spontaneous } ^{51}\text{Cr release}) \times 100}$$

Maximal release was calculated by freezing and thawing the target cells three times. Values are means of duplicates Spontaneous release of targets was as follows expt 1: C3H = 5.1% per h, R 1(TL$^+$) = 2.5% per h. Expt 2. C3H = 4.7% per h; BALB/c = 5.2% per h. Expt 3· C3H = 4.8% per h, B10A = 5.1% per h, B10A(4R) = 4.5% per h; ATL = 4.7% per h; C3H 0L = 3.4% per h, BALB/c = 5.2% per h.

Mixed lymphocyte cultures containing 10^5 per ml responder BALB/c spleen cells and 10^5 per ml 1,000 rad irradiated C3H stimulator cells were set up in Click's minimal essential medium supplemented with 5% selected fetal calf serum, 5×10^{-5} M mercaptoethanol, antibiotics and glutamine in 20 ml Falcon no. 3013 tissue culture bottles[1,2]. Culture flasks were incubated at an upright position in 5% CO_2 in air at 37 °C. Every 2 weeks the

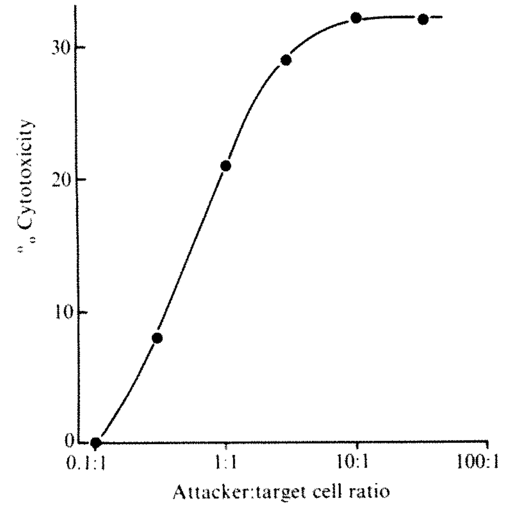

Fig. 1 C · C3 · 11 · 75 was titrated for its cytotoxic activity on C3H blast cells at various attacker to target cell ratios. The 3-h time point is given. Spontaneous release of C3H targets was 4.3% per h.

culture supernatant was replaced with new medium containing 10^5 per ml irradiated C3H spleen cells. The culture was regularly split when the cell density reached 5×10^5 cells per ml. The cell culture was called C·C3·11·75 as it is a BALB/c (H-2^d) anti C3H (H-2^k) T killer culture which was originally set up in November 1975 (ref. 2). After 5 months in culture C · C3 · 11 · 75 showed strong cell proliferation—about 10-fold over background—when challenged with C3H (H-2^k), CBA (H-2^k) and A (H-2^a) spleen cells but little or no stimulation was caused by DBA/1 (H-2^q), C57BL/6 (H-2^b), ASW (H-2^s) or BALB/c (H-2^d) spleen cells[2]. Strong cytotoxic activity was assayed on H-2^k spleen blast cells or tumour cells[2]. Beginning at about 10 months the cytolytic activity of C · C3 · 11 · 75 as assayed on tumour targets gradually disappeared as previously seen with other T killer cell lines[1–3]. However, as shown in Table 1, expt 1, cytolytic activity to C3H spleen blast cells is retained, while R1(TL$^+$) which expresses both the K end private specificity H-2.23 and the D end private specificity H-2.32 (ref. 5) is not lysed. Syngeneic BALB/c spleen blast cells are only lysed in the presence of phytohaemagglutinin (PHA) which only slightly increases cytotoxicity on C3H spleen cell blasts (Table 1, expt 2). The failure of C · C3 · 11 · 75 to lyse R1(TL$^+$) suggested that this killer cell line recognises other than the K or D region coded antigens. In support of this, Table 1 expt 3 shows that not only C3H, but also B10A, B10A (4R) and ATL, spleen blast cells are lysed. In contrast, C3H OL and BALB/c blast cells are not lysed. Taking the failure of C · C3 · 11 · 75 to lyse R1(TL$^+$) into account this would suggest that the determinants recognised by this cell line are encoded by genes to the right of the K region, that is, in the IA subregion[6]. As genes in this region are responsible for T-cell proliferation it was tested whether the spleen cells which are susceptible to lysis by C · C3 · 11 · 75 are able to stimulate cell proliferation. It can be seen from Table 1 that C3H OL does not stimulate cell proliferation, whereas BALB/c shows consistently significant stimulation. It is not clear what the basis of this stimulation might be. Cloning of this cell line will resolve the question of whether this cell line contains alloreactive as well as autoreactive cells. Aside from the stimulation by BALB/c much higher stimulation is seen with C3H, B10A and ATL spleen cells, which are good targets in the cytotoxic reaction. It therefore seems that the original population of killer cells was heterogeneous, consisting of cells which recognise several specificities expressed on both tumour cells and spleen blast cells. Prolonged selection of this cell line by periodic stimulation with C3H spleen cells has resulted in a population which only kills targets expressing antigens coded by the IA subregion genes[6]. It is possible but not certain that these same antigens are responsible for the proliferation of this cell line. C · C3 · 11 · 75 is sensitive to anti-θ and complement lysis and is also lysed by an anti H-2^d serum in the presence of complement. It can be frozen in liquid nitrogen and will start to proliferate after thawing with a doubling time of ~45 h. Both its proliferation and cytolytic activity depend on weekly stimulation with C3H spleen cells. A titration curve of its cytotoxic activity is shown in Fig. 1. Interestingly, the cytotoxicity has reached plateau values at attacker to targer ratios lower than 10:1. This supports the contention that C · C3 · 11 · 75 is a rather homogeneous T killer cell population. Maximal cytolysis is always found to be in the range 30–45% which may be because of heterogeneity in the target population or inhibition of the effector cells by soluble antigen.

Table 2 Proliferative activity of C · C3 · 11 · 75

Responder*	Stimulator	H-2	Proliferative activity† (c.p.m.)
5×10^4 C · C3 · 11 · 75	—	—	68 ± 13
—	BALB/c	ddddddd	77 ± 4

5×10^4 C · C3 · 11 · 75	C3H 0L	ddddkkk	168 ± 16
5×10^4 C · C3 · 11 · 75	C3H	kkkkkkk	12,138 ± 2,057
5×10^4 C · C3 · 11 · 75	B10A	kkkdddd	8,514 ± 723
5×10^4 C · C3 · 11 · 75	ATL	skkkkkd	5,802 ± 118
5×10^4 C · C3 · 11 · 75	Con A supernatant‡	—	137 ± 22

* 5×10^4 C · C3 · 11 · 75 were cultured with 5×10^6 per ml 1,000-rad irradiated stimulator spleen cells in 1-ml tubes in RPMI-1640 medium (ref. 2).

† Cultures were labelled with 0.5 µl ^{3}H-thymidine on day 2 and collected on day 3 (ref. 2).

‡ Con A supernatant was prepared by culturing mouse spleen cells with Con A for 2 days. The supernatant was filtered and tested as described in refs 7 and 8.

Recently it was reported that alloreactive killer cells can be propagated up to 5–7 months by weekly stimulation with supernatants of spleen cells stimulated with concanavalin A (Con A)[7,8]. It is likely that these cells which can be stimulated by Con A supernatant are quite different from those described here[8]. One important difference is that C · C3 · 11 · 75 cannot be stimulated by Con A supernatants (Table 2) but by spleen cells while the converse is true for the killer cells described by Nabholz *et al.*[8]. The establishment of an apparently continuously proliferating cytotoxic T-cell line which has retained specific biological functions may be the ideal tool to study the cell surface receptors and the function of this important class of lymphocytes.

An Lyt differentiated thymocyte subpopulation detected by flow microfluorometry

DATA on the T-cell antigens, Lyt 1, 2, 3 (refs 1, 2), relating to functional T-cell subsets, suggest that some peripheral T cells express restricted Lyt phenotypes, that is, Lyt 1^+23^- or Lyt 1^-23^+ (ref. 3). Evidence has been presented showing that two major subpopulations of lymphocytes, Lyt 1^+ T cells and Lyt 23^+ T cells, are committed to particular lines of functional differentiation in the immune response before encountering exogenous antigen in peripheral lymphoid tissue[4,5]. It has been suggested that the two major subpopulations representing T-cell help (Lyt 1^+) and T-cell cytotoxicity or suppression (Lyt 23^+) arise in the periphery from peripheral Lyt 123^+ cells[6]. Recent studies have concluded that as stem cells mature in the thymus, the thymic epithelium is important in determining which H-2 specificities the maturing T cells are able to recognise as self[7]. Previous cytotoxicity data have been interpreted as indicating that Lyt 1, 2, 3 antigens are expressed on each of most if not all, mouse thymocytes; that is, that most thymocytes are Lyt 123^+ (refs 1–4, 8–10). However, the data presented here suggest that the commitment to differentiation of the Lyt 1^+ or the Lyt 123^+ phenotype, and thus presumably the relevant functional differentiation occurs before cell migration from the thymus. Using flow microfluorometry (FMF) and anti-Lyt antisera, we demonstrate a normal thymocyte subpopulation which is not expressing Lyt 2 or Lyt 3 antigens (Lyt 1^+23^-). This subpopulation represents a significant constant proportion (10%) of normal thymocytes which is markedly increased following *in vivo* cortisone treatment. The data also show that Lyt 1 expression, rather than being decreased on cortisone-resistant thymocytes (CRT), as would have been predicted from previous cytotoxicity data[2,8], is expressed in increased amounts on CRT.

We have used thymocytes of C57BL/6 (B6) mice or the appropriate B6/Ly congeneic strains, anti-Lyt antisera and affinity-purified anti-mouse immunoglobulin (Ig) fluorescent staining reagents to re-examine the expression of Lyt 1, 2, 3 antigens on the thymocyte surface. Preparation of these sera and reagents has been described in detail elsewhere[11–13]. Immunofluorescence was analysed by FMF[14] on a FACS II interfaced to a PDP 11/40 computer[15]. This allowed us to quantitate total cell surface immunofluorescence on individual cells.

Figure 1*a*–*d* indicates that both anti-Lyt 1.1 and anti-Lyt 1.2 react with >99% of all thymocytes. The Lyt 1 expression for both alleles is increased on CRT (Fig. 1*b*, *d*) relative to normal thymocytes (Fig. 1*a*, *c*), as indicated by the increased level of fluorescence on Lyt 1^+ cells; for example, 50% of CRT have >1,200 fluorescent units per cell compared with 19% of normal thymocytes (Fig. 1*a*, *b*). In contrast, anti-Lyt 2.1 and anti-Lyt 2.2 (Fig. 1*e*–*h*) react with only 90% of normal thymocytes and either allele is expressed on only 30–50% of CRT. When the Lyt 2 reagents were used at saturation, the mean peak of fluorescence of the positive cells on the cell frequency distribution histogram indicated that Lyt 2^+ CRT cells were expressing less detectable antigen on the surface than normal thymocytes. Normal B6 thymocytes from neonates are similar to those from adults in Lyt expression, indicating a constant 10% Lyt 2^- thymic subpopulation at least from birth.

There is an apparent correlation between the expression of Lyt 3 and that of Lyt 2. (1) The same number of normal

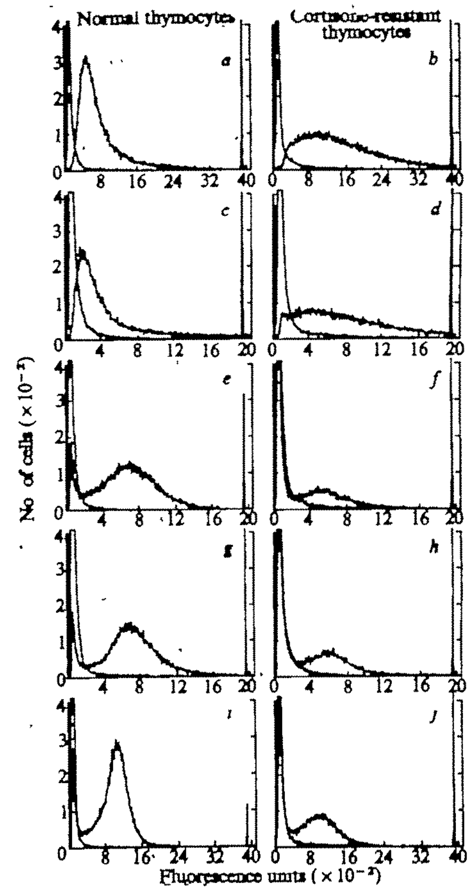

Fig. 1 Normal or cortisone-resistant thymocytes from 3–5-month C57BL/6 (B6) or appropriate B6/Ly congeneic mice were treated with anti-Lyt antisera and fluorescent goat anti-mouse immunoglobulin (Fl-GAMIg). CRT were obtained 36–40 h after intraperitoneal administration of 0.25 mg cortisone acetate in suspension. For each analysis, 10^6 cells, suspended in phenol red-free HBSS modified with 0.1% NaN_3 and 0.1% bovine serum albumin were incubated for 45 min at 4 °C with antiserum and washed twice by centrifugation in 2 ml volumes of the same medium. The anti-Lyt-sensitised cell pellets were then resuspended in about 50 µl residual liquid, incubated for 30 min with Fl-GAMIg, washed twice, resuspended in 0.4 ml of modified HBSS, and analysed by FMF on a FACS II (Becton Dickinson) which is equipped with an argon ion laser operated at 488 nm wavelength and 200 mW for fluorescein excitation. The beam is focused by a 39-mm focal length spherical lens. Fluorescence is detected with an S-11 response photomultiplier tube at 520 V with 520-nm and 530-nm barrier filters. Each section of the Figure displays two cell frequency histograms, positive thymocytes (normal or CRT) and the appropriate negative control cells (normal or CRT), treated equally with the same antiserum and fluorescent reagent. Each histogram represents the fluorescent staining intensities of 50,000 viable cells; viability determined by light scatter[14]. Data were collected on the FACS II in a 1,000 channel distribution and stored in a PDP 11/40 computer (Digital Equipment Corporation) interfaced to the FACS II (ref. 15). Fluorescence unit values have been corrected for differing amounts of amplification used when collecting fluorescence signals from cells treated with different reagents. *a*,*b*, Anti-Lyt 1.1; positive thymocytes and CRT were obtained from B6/Ly 1.1 mice, control cells were obtained from B6 mice Cell suspensions were incubated with 10 µl of anti-Lyt 1.1 obtained from a pool of multiple bleedings from a single mouse. This pool and ~20 similar pools were obtained from (B6/N × BALB/c AnN)F_1 mice immunised 3–10 times with B6/Ly 1.1 normal thymocytes. All antisera were routinely absorbed with lymphoid cells expressing the opposite Lyt allele, and were centrifuged at 100,000 *g* (30 p.s.i., in a Beckman airfuge) for 20 min to remove complexes and aggregates immediately before use. *c*,*d*, Anti-Lyt 1.2, these cell suspensions were the same as those in *a*,*b*, except that this antiserum recognises the opposite Lyt 1 allele and therefore B6 cells are the positive populations, and B6/Ly 1.1 cells are negative. Anti-Lyt 1.2 was obtained from a pool of C3H/An mice immunised with CE normal thymocytes. 25 µl of this antiserum was used for analysis of Lyt 1.2 expression *e*,*f*, Anti-Lyt 2.1; the positive cell populations in this case were obtained from B6/Ly 2.1, 3.1 mice, and cells from B6/Ly 1.1 mice were used as controls. This antiserum was raised by immunisation of B6/H-2^k mice with CE normal thymocytes. The antiserum was from a highly cytotoxic pool and was also extremely high in anti-Lyt activity measured by this method only 10 µl at 1/10 being needed for these analyses. *g*,*h*, Anti-Lyt 2.2; the positive cell populations were obtained from B6 mice and the negative cell populations from B6/Ly 2.1, 3.1 mice. Anti-Lyt 2.2 anti-serum was obtained as described for the anti-Lyt 1.1 except that (C3H/HeN × B6/Ly 2.1)F_1 mice were immunised with normal B6 thymocytes. This antiserum was used at 15 µl for saturation level of staining analyses. *i*,*j*, Anti-Lyt 3.2; positive cell populations were obtained from B6/Ly 2.1 mice and negative cell populations from B6/Ly2.1, 3 1 mice. Anti-Lyt 3.2 antiserum was made from a pool of immunised mouse sera selected for high levels of cytotoxicity. The mice used for this serum were C58 immunised with CE normal thymocytes. Saturation levels of this antiserum were obtained with 15 µl of 1/10 diluted antiserum.

0028–0836/79/0277—0478$01.00

thymocytes are positive with reagents detecting either antigen (compare Fig. 1 *e*.*g*.*i*); (2) like Lyt 2 expression on CRT, a higher proportion of Lyt 3^- cells is seen with CRT than with normal thymocytes (compare Fig. 1*i*, *f*); (3) treatment with both anti-Lyt 2 and anti-Lyt 3 still leaves 10% normal thymocytes unstained.

Each anti-Lyt 2 and anti-Lyt 3 histogram shows two nearly symmetrical peaks (Fig. 1*e*-*j*) one of which falls beneath the negative-control histogram peak and contains about 10% of the total cells, the second of which falls almost entirely outside the range of the negative cell control and contains 90% of the total cells. If, in non-saturating conditions, increasing amounts of anti-Lyt 2 are added, the entire dominant positively stained peak of cells is shifted to the right (brighter), whereas the minor peak of negative cells (unstained cells) is unchanged. By contrast, each histogram obtained with anti-Lyt 1.1 or anti-Lyt 1.2 shows one major asymmetrical peak containing >99% of the cells. Although this peak partially overlaps that of the negative control, several lines of evidence indicate that all cells under the major peak are Lyt 1^+: (1) if more anti-Lyt 1 is used, the entire major peak shifts to the right (brighter), such that it no longer overlaps the control peak; (2) the major peak is always unimodal with a trail of bright cells, and (3) a small distinct peak (<0.5% of cells) invariably precedes the major peak and may represent Lyt 1^- thymocytes. In summary, the frequency distribution histograms for normal thymocyte expression of Lyt 1 can be described as a major peak of 'dull' positive cells with a trail of 'bright' cells. In contrast, the Lyt 2.3 histograms can be described as a minor peak of negative cells and a major peak of positive cells with relatively homogeneous staining. The CRT pattern for Lyt 1 is a relatively flat distribution of positive cells with two approximately equal peaks of Lyt 2^+3^+ and Lyt 2^-3^- cells. Thus, the patterns of Lyt 1.1 and Lyt 1.2 antigen expression resemble each other, as do those of Lyt 2.1, Lyt 2.2 and Lyt 3.2. Expression of Lyt 1 antigen is, however, different from Lyt 2 and Lyt 3.

Dual-parameter analysis of forward light scatter (1–15°), a relative measure of thymocyte size[16], and of immunofluorescence for expression of these Lyt antigens was carried out on normal thymocytes and CRT. These analyses indicate that Lyt 23^- cells are medium to large in size and express relatively high amounts of Lyt 1. In contrast, the majority of Lyt 23^+ cells are smaller and express lower amounts of Lyt 1. Figure 2 shows light scatter profiles of B6 CRT showing different staining levels. It is important to remember that fluorescence intensity by this method reflects total antigen expression, not necessarily antigen density.

Recently we described a series of mouse thymic lymphomas which seemed to display limited or restricted Lyt phenotypes similar to functional differentiated, peripheral T cells[13]. Most of the tumours in that study were TL^+. As TL antigen expression is restricted to thymocytes and T-cell lymphomas[17], we suggested that a normal thymocyte subpopulation existed which was TL^+ and already differentiated for Lyt antigen phenotype. Other data[18] also predict the functional differentiation of TL^+ thymocytes. The results presented here confirm the existence of a significant subpopulation of normal thymocytes which are differentiated in expression of Lyt antigens. Similar results have been obtained for several other strains of mice, including BALB/c, A/J, C3H and DBA/2.

The increased expression of Lyt 1 on CRT, as detected by these antisera and FMF, was not predicted by previous cytotoxicity data[4,8]. Increased expression of Lyt 1 cannot be attributed to induction of antigen expression during the tests because the entire procedure was carried out at 4°C in Hanks' balanced salt solution (HBSS) containing 0.1% NaN_3.

The increased expression of Lyt 1 on CRT is probably not attributable to Fc binding of the anti-Lyt antisera because; (1) there are marked fluorescence profile differences between anti-Lyt 1 and anti-Lyt 23 on the same cell suspension (2) appropriate negative congeneic cell controls are not stained in the same conditions with the same antisera (see Fig. 1). (3) staining a 50:50 mixture of cells from mice expressing both alleles (for example, Lyt 1.1 plus Lyt 1.2) yields only 50% positively stained cells (data not shown). This considerably decreases the possibility of activation of Fc regions of Ig leading to nonspecific staining of Lyt 1^- cells. (4) As a precaution, all alloantisera and fluorescent reagents were ultracentrifuged at 100,000 *g* before being used in these tests.

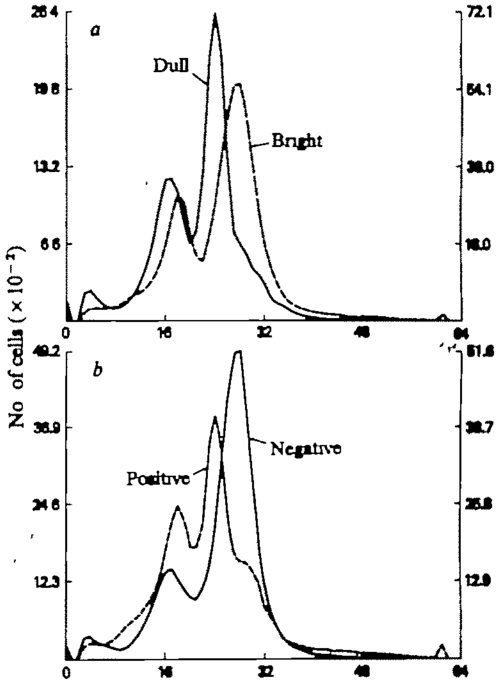

Fig. 2 CRT from C57BL/6 (B6) mice were prepared and treated with anti-Lyt antisera and Fl-GAMIg as described for Fig. 1. FMF analysis was carried out as described in Fig 1, except that data were collected and stored in the computer on both light scatter (LS) and fluorescence (Fl) simultaneously for 10^5 total cells (not selected on LS) Data were collected in a 64 × 64 matrix such that the *x*-axis represented LS, the *y*-axis Fl, and the *z*-axis the cell number at each intersection of LS and Fl. Data collection and analysis are described elsewhere[13]. Here, upper and lower thresholds (windows) were selected on Fl intensity and all LS data within each window are shown as the number of cells versus increasing LS *a*, The LS of B6 CRT staining with different intensities with anti-Lyt 1 2 Dull cells (——) were selected as those with intensities of <384 Fl units (see Fig. 1*d*). This corresponds to the majority of normal thymocytes and 20.6% of viable CRT in this example. The bright (– – –) cells were selected as those with intensities >640 Fl units (see Fig 1*d*) and here represented 65% of the viable CRT The first peak (cells <21 LS units) in all the histograms in this Figure represents dead cells which have lower scatter intensity than viable cells[14], and which in these CRT preparations comprised about 30% of the total cell population. *b* The LS of B6 CRT staining with different intensities with anti-Lyt 2.2. the negative (——) cells were selected as those with intensities <150 FL units (Fig. 1*h*) and represented 51.5% of the viable CRT in this experiment The positive cells (– – –) were selected as those with intensities >260 Fl units (Fig 1*h*) and represented 44.8% of the viable CRT

The discrepancy between complement-mediated, antibody-dependent cytotoxicity and FMF analysis may be explained by one or more of the following. (1) Our technique is more accurate in terms of the ability to measure the quantity of surface antigen expressed on individual cells. Thus, we were able to detect the minor Lyt 1^+, 23^- subpopulation of thymocytes. (2) There might be a quantitative difference in the expression of Lyt 1, and cytotoxicity assays with complement might kill only Lyt 1 'bright' cells. Varying levels of Lyt 1.1 antigen expression on peripheral T cells have already been suggested to explain a titrated depletion of cytotoxic effector T cells with anti-Lyt 1.1[19]. However, other factors are involved, because easily killed normal thymocytes express less Lyt 1 than do CRT by quantitative immunofluorescence (Fig. 1*a*–*d*). Furthermore, there is no selective loss of Lyt 1 bright cells after cytotoxic depletion of CRT (data not shown). (3) Complement-mediated, antibody-dependent cytotoxicity only detects surface antigen expression when the antigen is recognised by antibody capable of binding complement, for example, antibody of the IgG2 or IgM classes. Most of the presently available highly cytotoxic pools of anti-Lyt antisera contain considerable amounts of non-cytotoxic IgG1, anti-Lyt antibody (manuscript in preparation), which may block effective complement-mediated cytotoxicity. Using a selected pool of anti-Lyt 1.2, with no detectable IgG1, we have been able to kill >90% of CRT. (4) Other cell surface changes related to the differentiated state of the CRT may make cells more or less sensitive to antiserum plus complement. Recent work has suggested that specific lipids inserted into the membranes of tumour cells reduce the sensitivity to such cytotoxicity[20]. (5) The genetic locus for Lyt 1 may be a complex with more than one specificity. For example, a specificity, Lyt 1.1^a, may define a T^H subset capable of helper cell function, whereas Lyt 1.1^b defines a T-cell subset required for delayed-type hypersensitivity. These specificities could potentially be further defined by genetic differences, or the use of monoclonal antibodies obtained by anti-Lyt-myeloma fusions. Extensive analysis of the Lyt 1 alleles has been complicated by the fact that the titre of the anti-Lyt 1.2 antisera is much lower than that of anti-Lyt 1.1 antisera. This has also hindered comparative analysis of these antigens from previous cytotoxic data[19,21]. However, results with a limited number of anti-Lyt 1.2 antiserum pools indicate that expression of Lyt 1.2 closely resembles that of Lyt 1.1 in the FMF immunofluorescence analysis of thymocytes, CRT and peripheral T cells. Furthermore, preliminary evidence suggests that peripheral T cells display similar Lyt 123 phenotypes to those detailed here for CRT.

The accepted hypothesis suggests that all thymocytes and therefore all peripheral T cells express Lyt 123 during differentiation[3]. Our data suggest that there may be two lines of thymic differentiation; one line which expresses Lyt 1 but not Lyt 2 or 3 and a second line which expresses all three antigens during differentiation. Thus, there would be two thymocyte sublines corresponding to Lyt 1$^+$ cells and Lyt 123$^+$ cells. The functional capabilities of the peripheral T cells could be determined by or reflect the phenotype expressed in the thymus.

We thank the members of the Laboratory of Microbial Immunity, and Drs Michael Potter, F-W. Shen, E. A. Boyse and John Wunderlich for their help and support. Mice were raised from stock originally supplied by Dr E. A. Boyse. The anti-Lyt 1.2,-Lyt 2.1 and -Lyt 3.2 sera were supplied by Drs F. W. Shen and E. A. Boyse.

Substance P causes direct depolarisation of neurones of guinea pig interpeduncular nucleus *in vitro*

SEVERAL lines of evidence suggest that the undecapeptide, substance P, is involved in synaptic transmission in various areas of the central nervous system[1]. The development of a specific radioimmunoassay and new immunohistochemical techniques has allowed the identification of several specific but putative pathways involving substance P in the brain[2,3]. In particular, the cell bodies in the medial habenula and probable nerve terminals in the interpeduncular nucleus contain high concentration of substance P[3]. In addition, lesioning of the habenula causes a drastic decrease in the substance P concentration in the interpeduncular nucleus[4]. These findings imply that substance P may act as a transmitter in the habenulo-interpeduncular system. Therefore, in the present study, the effect of substance P has been examined *in vitro* on the interpeduncular neurones in an isolated guinea pig brain stem preparation. Substance P depolarised the membrane of the interpeduncular neurones. This finding supports the possible transmitter role of substance P in the central nervous system.

The brain of an adult guinea pig of either sex was removed from the skull, placed on filter paper soaked with Krebs solution with the ventral surface of the brain facing upwards and divided along the midline. A block of the brain stem which included the thalamus, hypothalamus, mamillary body and interpeduncular nucleus was made by removing the majority of the brainstem, hippocampus and the cerebral cortex. A slice ~500–600 µm thick was cut from the medial surface using a stainless steel slicer. Incubation, stimulation and recording procedures are described in detail elsewhere[5]. The slice was continuously perfused with Krebs solution equilibrated with 97% O_2 and 3% CO_2 at 36 °C. Under a binocular microscope the stimulating electrodes, consisting of a pair of tungsten wires were placed gently on the habenulo-interpeduncular tract. For extracellular and intracellular single cell recordings, conventional glass microelectrodes were used.

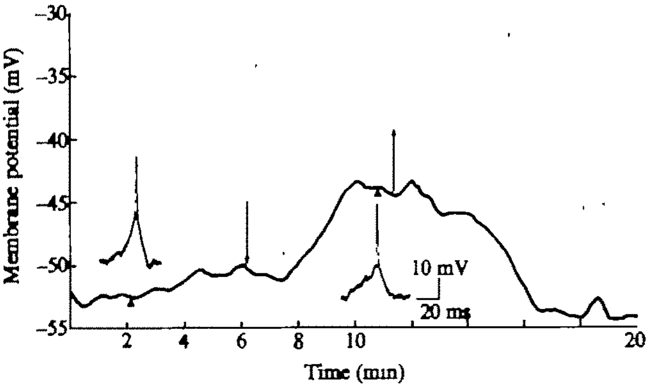

Fig. 1 Effects of substance P on the resting membrane potential of the interpeduncular neurone. Upward and downward arrows represent the duration of a perfusion with a Krebs solution containing 10^{-7} M substance P and the commencement of washing with normal Krebs solution. Inserts illustrate action potentials recorded at points indicated by (△) and (▲). Upward deflections represent positive polarity.

Intracellular recordings from interpeduncular neurones show their resting membrane potential to be 52.8±6.7 mV. Each neurone responded to stimulation of the habenulo-interpeduncular tract (50–100 μs duration) with an excitatory postsynaptic potential which evoked an action potential. No hyperpolarising potentials were observed. In most records spontaneous firing occurred.

In 10 stable extracellular records, substance P (10^{-7} M) was shown to increase reversibly the firing rate of the interpeduncular neurones 1.5 to 5-fold except for one neurone on which no obvious change occurred. L-glutamate also increased the firing rate of the interpeduncular neurones and dose–response curves show 10^{-5} M L-glutamate to be roughly equipotent with 10^{-7} M substance P. In Fig. 1, intracellular records show that substance P (10^{-7} M) induced a depolarisation of ~8 mV. The original membrane potential was restored by washing. The excitatory action of substance P was preserved in low calcium medium.

Although the excitatory action of substance P observed in the present study may be nonspecific, comparable studies on slices cut from the hippocampus and cerebellar cortex which contain almost no substance P show substance P to exert no effect. Similar negative results were reported by Dodd and Kelly[6].

I thank Professor M. Otsuka for providing substance P and for helpful suggestions, and Professor H. Kuriyama for valuable discussions.

Depolarisation-induced changes in muscarinic cholinergic receptors in synaptosomes

PROLONGED exposure of receptors to ligands can result in a reduction in the number of available binding sites[1–8]. This constitutes one possible homeostatic mechanism in the control of interneural communication as there is a functional desensitisation of target tissues. The association between transmission-linked events and the extent of ligand binding can be investigated conveniently in synaptosome preparations. Here we present evidence for what may be a similar desensitisation phenomenon for pre- or postsynaptic muscarinic acetylcholine receptors on synaptosomal membranes as a result of depolarisation mediated via prolonged or persistent opening of sodium channels.

Depolarisation of synaptosomes and cells by electrical stimulation or veratrine treatment cause, through membrane depolarisation, augmentation of metabolic rates, Ca^{2+} uptake, membrane protein phosphorylation, Ca^{2+} dependent transmitter release, cyclic GMP levels, and increased turnover of neurotransmitters[9–13]. All these effects, together with K^+ efflux, are abolished or greatly reduced by blocking the Na^+ channels with tetrodotoxin, which, in the absence of stimulation, has no observable effect[9,10,12,13].

Muscarinic receptors in the rat brain have been characterised in detail using tritiated agonists and antagonists[14–18]. The binding of one such radiolabelled antagonist, [^{3}H]*N*-methylatropine (^{3}H-NMA), to muscarinic receptors on synaptosomal membranes was greatly reduced (up to 50%) following treatment of synaptosome preparations[19] with electrical pulses, and to a lesser extent, after veratrine treatment. This effect was totally abolished when tetrodotoxin (1 μM) was present during stimulation (Table 1). With increasing duration of stimulation, the number of receptors decreased at a considerably faster rate than did the control unstimulated, synaptosome membranes (Fig. 1*a*). In addition, the extent of the reduction in ligand binding appeared to be proportional to stimulus size over the current range 600–800 mA (Fig. 1*b*). Depolarisation with 56 mM K^+ in contrast produced no change in the number of antagonist binding sites.

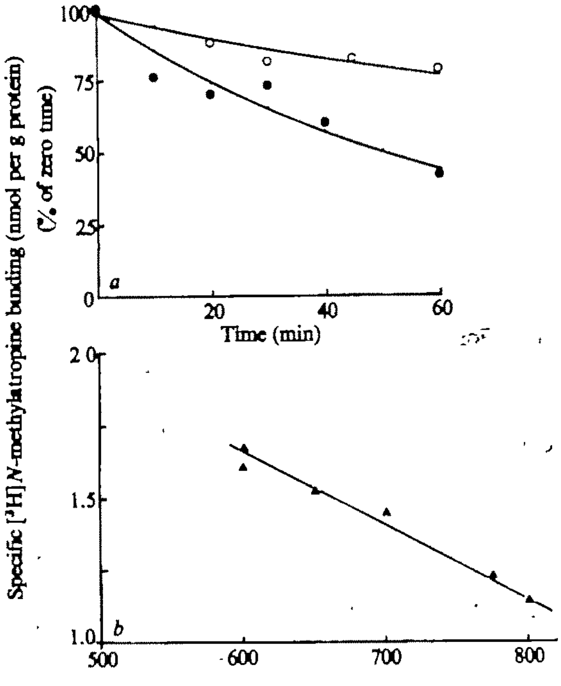

Fig. 1 Time and stimulus-dependence of synaptosomal receptor population. Synaptosomes were prepared from cerebral cortex[19] and incubated at 37 °C in Krebs-phosphate medium containing 10 mM glucose in Warburg respirometer flasks. *a*, Stimulation was applied through gold-ring electrodes for the times indicated, and the reaction was terminated by centrifugation. Hypo-osmotic lysis of the resultant pellets, at 0 °C in 10 mM phosphate buffer *p*H 7.0 followed by centrifugation of the lysed suspension gave a fraction of synaptosomal membranes. These were stored at −80 °C before measurement of receptor binding capacity as described in Table 1 legend. The open symbols and closed symbols represent binding capacities in the absence and presence respectively of electrical stimulation. *b*, The relationship between receptor loss and the size of the stimulus was investigated by changing the current delivered through the electrodes. In each case, stimulation lasted for 30 min. A typical experiment is shown for a group of six samples each of which showed a different rate of decline of antagonist binding to the muscarinic receptors.

It may be that the depolarisation-induced loss of ^{3}H-antagonist binding is due to the action of cytoplasmic or lysosomal enzymes (or other soluble factors) released from synaptosomes. These could modify the ligand-binding properties of receptors by proteolysis or other biochemical actions. This possibility was investigated in several ways. The presence of chymotrypsin (3 μM) during the 1-h synaptosome incubation did not cause any reduction in binding nor did inclusion of phenylmethyl sulphonyl fluoride (a serine protease inhibitor) at 30 μM prevent the electrically stimulated loss. The effects of endogenous synaptosomal proteolytic enzymes on muscarinic receptors were tested by adding synaptosomal lysates to intact synaptosome preparations. Addition of freeze-dried protein

Stimulation in presence of tetrodotoxin	93±1	(4)	97±4	(5)	—		—		—	

Synaptosomes prepared from rat cerebral cortex[19] were incubated at 37 °C in Krebs-phosphate medium containing 10 mM glucose and tetrodotoxin (1 μM), where appropriate, in Warburg respirometer flasks. After preincubation for 30 min stimulation was applied by addition of veratrine (76 μM), potassium (56 mM), glutamate (100 and 200 μM) or carbachol (0.1–100 μM) or by application of electrical pulses[12] for 30 min. Pelleted synaptosomes were then exposed to hypo-osmotic lysis at 0 °C in 10 mM phosphate buffer pH 7.0 and the pellet of synaptosomal membranes obtained after centrifugation (100,000g, 10 min) stored at −80 °C. Subsequent receptor binding was performed as described previously[16] using saturating concentrations of [^{3}H] N-methylatropine (10^{-8} M) and a rapid centrifugation method[17]. Nonspecific binding, determined by incubating the membranes and ^{3}H-NMA with a high concentration (1 μM) of 3-quinuclidinylbenzilate or atropine, was in general less than 10% of the specific binding. Values for controls were in the range 1–2 nmol ^{3}H-antagonist per g synaptosomal protein. Results are means ± s.e.m. for the number of independent experiments given in brackets.

* Significantly different from control, $P < 0.005$ (using a completely randomised analysis of variance).

80 μg ml^{-1} (equivalent to 20% of the total osmotically releasable synaptosomal protein) to the incubation did not reduce the binding of ^{3}H-NMA to the receptors. A concentration of 150 μg ml^{-1} was required to produce a 15–20% loss in binding over 1 h. The effects shown in Table 1 would require lysis of 50–80% of the incubated synaptosomes on electrical stimulation; such damage has not been observed in previous experiments[11,12]. As the 'proteolytic potency' of the lysate may have been reduced by extraction and freeze-drying, synaptosomal membranes were incubated in the medium obtained from a previous incubation of intact stimulated synaptosomes. This medium would contain any released soluble enzymes. No loss of binding of ^{3}H-NMA was observed in this experiment. Furthermore, the loss in numbers of muscarinic receptors was not accompanied by a change in activity of the membrane-bound enzymes, Na$^+$/K$^+$-ATPase or acetylcholinesterase, or any detectable changes in the Coomassie blue staining pattern of the protein bands of solubilised synaptosomal membranes, when electrophoresed on SDS-polyacrylamide gels. In these experiments, electrical stimulation of synaptosomes prelabelled with the irreversible label, ^{3}H-propylbenzilylcholine mustard[15], showed no evidence of proteolysis of the specifically labelled 83,000 molecular weight[20] binding site of the muscarinic receptor or of release of the membrane-bound receptor into the medium. Thus the observed fall in the antagonist binding capacity seems to be a specific effect linked to the depolarisation event or its sequelae rather than to any gross degenerative effects triggered by the stimulus.

The exposure of crude synaptosome preparations to high concentrations of muscarinic agonists is apparently without effect on the subsequent time-dependent binding kinetics of agonists or antagonists to the receptor population[16,18]. Our results (Table 1) similarly showed that pretreatment of synaptosomes with carbachol, or glutamate (to simulate transmitter release) or potassium (which is released during depolarisation) had no effect on subsequent ^{3}H-NMA binding.

Our experiments suggest that the decreased binding of ^{3}H-NMA to muscarinic receptors on electrical stimulation or on veratrine treatment is not a direct effect of these agents since the receptor 'loss' is inhibited by low concentrations of tetrodotoxin, which blocks sodium channels. The decreased binding seems to be a result of depolarisation of the synaptosome. One of the main consequences of depolarisation is the release of neurotransmitters. However, the loss of binding activity does not seem to be a result of neurotransmitter–receptor interactions as the phenomenon is not triggered by treatment of the synaptosomes with carbachol or glutamate. Hence the phenomenon is different from the reported agonist-induced loss of β-adrenergic receptors[6,7]. Furthermore, the fact that K$^+$ depolarisation does not decrease ^{3}H-NMA binding suggests that the receptor loss is specifically associated with the persistent opening of Na$^+$ channels.

One possibility is that an agent, released with the neurotransmitter (presumably acetylcholine) modifies the muscarinic receptor. However, any modification of the receptor does not seem to be a general proteolysis; the molecular weight of the receptor and the activity of certain membrane-bound enzymes are not altered by electrical stimulation. The hypothetical factor would have only a transient activity in reducing binding to the receptors in view of the fact that incubation of the medium from electrically stimulated synaptosomes with intact synaptosomes has no effect on ^{3}H-NMA binding. As synaptosomes consist of intact presynaptic structures, commonly carrying parts of the postsynaptic membranes and thickenings, such a factor would be released, along with the neurotransmitter, in high concentration into the synaptic cleft. Any such factor could therefore rapidly modify both postsynaptic and presynaptic receptors before inactivation or diffusion from the cleft.

An alternative possibility that the loss is principally of presynaptic receptors located on the synaptosome membrane and is caused by endocytosis of receptors or a modification of this membrane which is initiated by depolarisation. This hypothesis would imply that at least 50% of the receptors in the preparation were localised presynaptically as this is the observed loss of ^{3}H-NMA binding. There is evidence for the presynaptic localisation of muscarinic receptors[21,22]: in the present experiments carbachol (200 μM) stimulated amino acid release by 30–80%.

One can speculate that the modification of the binding properties of the muscarinic receptor, if reversible *in vivo*, could provide a mechanism for desensitisation, which is known to occur with considerable facility in muscarinic receptor-linked responses[23,24]. The mechanism of receptor 'loss' is being investigated further.

Voltage-dependent calcium current induced by serotonin

CALCIUM ions have a central role in the regulation of neural activity[1,2]. Changes in intracellular calcium concentration affect membrane permeability to other ions and thereby alter membrane excitability[3]. Furthermore, calcium is required for transmitter release from nerve terminals[4]. A neurotransmitter that specifically induces an inward calcium current might have profound effects. We report here that in some neurones of *Aplysia*, serotonin can induce such a calcium current. A previous investigation[5] revealed that iontophoretically applied serotonin elicited an unusual excitatory response in some neurones of *Aplysia*. At hyperpolarised potentials the neurotransmitter produced a slow excitation (component 1) that behaved simply as an increase in sodium conductance, similar to the A′ response of Gerschenfeld and Paupardin–Tritsch[6]. At depolarised potentials (>−30 mV), the response was voltage dependent and behaved as a regenerative inward current (component 2). At all potentials, the slow excitatory response to serotonin was insensitive to changes in extracellular chloride or potassium concentration. However, in sucrose-substituted sodium-free solutions, the response was greatly attenuated. Although a calcium current was not excluded, it was tentatively suggested that sodium was responsible for the regenerative inward current as well as for component 1. Further study has now shown that the regenerative inward current component is carried by calcium ions.

The slow excitatory response was elicited by iontophoretic application of serotonin on unidentified neurones of the left caudal quarter of the abdominal ganglion and cells B1 and B2 of the buccal ganglia of *Aplysia californica*. Iontophoretic pulses of serotonin were applied at a constant rate (once every 5 min) throughout the experiment. Neurones were voltage clamped by the single-electrode method of Wilson and Goldner[7]. Methods are the same as those described previously[5].

Calcium currents in many preparations are blocked by the divalent cations cobalt[1,8,9] and manganese[1,9,10]. Figure 1*a* shows that component 2 of the excitatory response to serotonin is strongly attenuated by 25 mM cobalt in calcium-free seawater. This was consistently observed in all of the seven cells tested with cobalt. Component 1 was affected to varying degrees; in 3 cells it was minimally affected, but in four it was greatly reduced. In the cell illustrated, component 1 was only slightly attenuated. Manganese (25 mM in calcium-free seawater) was also a potent blocker of the excitatory response to serotonin (Fig. 1*b*). In the six cells tested, it reversibly attenuated both components of the excitatory response to serotonin. The actions of manganese on component 1 are reminiscent of the effects of this divalent cation on the fast sodium-dependent response to dopamine observed by Ascher[11].

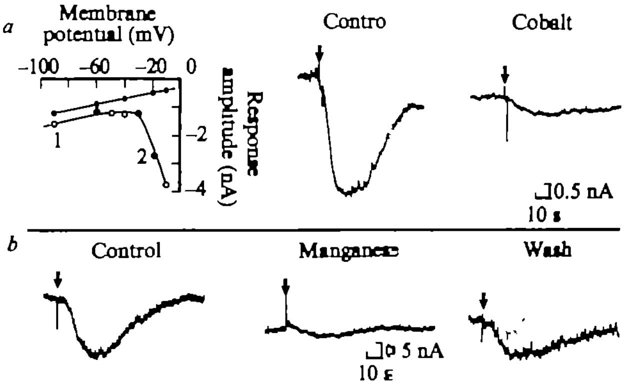

Fig. 1 Actions of calcium blockers cobalt and manganese. The graph in *a* shows that 25 mM cobalt in calcium-free seawater blocks component 2 (the inward current at potentials more depolarised than −30 mV) but minimally affects component 1 (the inward current at more hyperpolarised potentials). The current traces in *a* are from the same cell and show responses to serotonin when the membrane potential was voltage clamped to −10 mV in normal seawater (Control) and in the presence of cobalt. Inward current is represented by a downward deflection. *b* Shows the current response to serotonin in another cell when the membrane potential was clamped to −14 mV while in normal seawater (Control), in 25 mM manganese in normal seawater, and following replacement of normal seawater (Wash) ○, Control; ●, 25 mM CO^{2+}.

When extracellular sodium was replaced with glucosamine, component 1 was attenuated within 15 min. This effect was rapidly reversed with the reintroduction of sodium. As shown in Fig. 2, component 2 was affected differently, in that the response to serotonin was prolonged. In two of the three cells studied, the response was still present after 40–50 min in sodium-free seawater. In the third cell, component 2 of the response was initially prolonged, but within 40 min had declined to zero amplitude. The response recovered slowly in normal seawater, requiring 60 min for 50% reversal. Thus, component 1 is always quickly and reversibly blocked by sodium-free solutions, whereas component 2 is either left unblocked or is very slowly attenuated. In squid axon, prolonged exposure to sodium-free solutions increases intracellular free calcium[12], and intracellular accumulation of calcium has been shown to block an inward calcium current[13,14]. This may be the basis of our observed depression of component 2 in sodium-free solutions. It was previously reported that the serotonin response was greatly reduced by sucrose-substituted sodium-free seawater[5]. The present results using other Na^+ substitutes suggest that this effect may be related to the decreased ionic strength of the solution or to some nonspecific action, rather than the reduced sodium concentration.

The different ionic sensitivities of the two components of the excitatory response to serotonin indicate that these are independent conductance changes. This is further supported by the observation that in some cells only component 1 was observed, whereas in others only component 2 could be elicited by iontophoresis of serotonin. Component 1 is probably the A′ response of Gerschenfeld and Paupardin-Tritsch[6] and is due to an increase in sodium conductance. The results presented here suggest that calcium is carrying the regenerative inward current at depolarised potentials (component 2).

This is the first demonstration that iontophoretic application of a neurotransmitter can elicit a current carried exclusively by calcium. Of further interest is the regenerative nature of the inward current. Regenerative inward calcium currents have been observed in other systems. A regenerative calcium current is responsible for the calcium component of action potentials[1]. It is also thought to underlie the burst firing behaviour of neurones[15,16], and Eckert and Lux[15] have suggested that, in

0028-0836/79/0277—0483$01.00

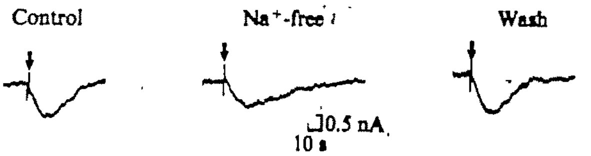

Fig. 2 Effects of sodium-free seawater on current response to serotonin. Na$^+$-free trace was taken after 55 min in sodium-free solution. Membrane potential was voltage clamped to −18 mV. Glucosamine HCl completely replaced NaCl in the seawater. The pH of the solution was adjusted to 7.2 by addition of 60 mM $Mg(OH)_2$. 'Control' and 'Wash' solutions were normal seawater at pH 7.2 to which 60 mM $MgCl_2$ had been added.

Helix, this current is carried exclusively by calcium. At the presynaptic terminal of squid giant synapse, Katz and Miledi[10] characterised a regenerative inward calcium current that they hypothesised was responsible for transmitter release. Induction of a regenerative calcium current by serotonin may serve to modulate one or more of these processes.

Demonstration of a neurotransmitter-evoked calcium current suggests the possibility of transmitter regulation of intracellular calcium concentration. As intracellular calcium is a principal regulator of a variety of cell functions, this transmitter action is of great physiological significance. Modulation of transmitter release is one possible role for a serotonin-induced calcium current. Our finding may explain some observations reported in the literature. Shimahara and Tauc[17] and Kandel *et al.*[18] have proposed that serotonin mediates presynaptic facilitation. In some cells of *Aplysia*, serotonin can broaden action potentials in the presence of tetraethylammonium, and Klein and Kandel[19] suggested that a calcium current is modulated by the neurotransmitter. Dretchen *et al.*[20] have observed that transmitter release at the mammalian neuromuscular junction is enhanced by serotonin, perhaps through a cyclic AMP mechanism. In neuroblastoma–glioma hybrid cells cultured with normal mouse myotubes, Christian *et al.*[21] have shown that serotonin caused release of acetylcholine and facilitated synaptic release. The regenerative inward calcium current induced by serotonin described here may underlie the presynaptic modulatory actions of serotonin, and may also have other important, as yet unrecognised, regulatory effects on neuronal function.

We thank Drs W. A. Wilson and H. R. Guy for discussions. T.P. held an NRC Resident Research Associateship.

Inhibition of Ca^{2+} efflux from mitochondria by nupercaine and tetracaine

IT was reported by Mela[1,2] that local anaesthetics stimulate Ca^{2+} uptake by rat liver mitochondria. This has been attributed to the protective action of these compounds on mitochondrial structure[3,4], particularly with regard to inhibition of phospholipase A (refs 5, 6). However, another possibility is that local anaesthetics affect differentially, and more directly, the uptake and efflux of Ca^{2+}. Recent evidence suggests that mammalian mitochondria, in addition to the well documented route for Ca^{2+} accumulation, have a different mechanism for Ca^{2+} release[7–9]. In the case of rat liver mitochondria, inhibition of Ca^{2+} uptake by the addition of

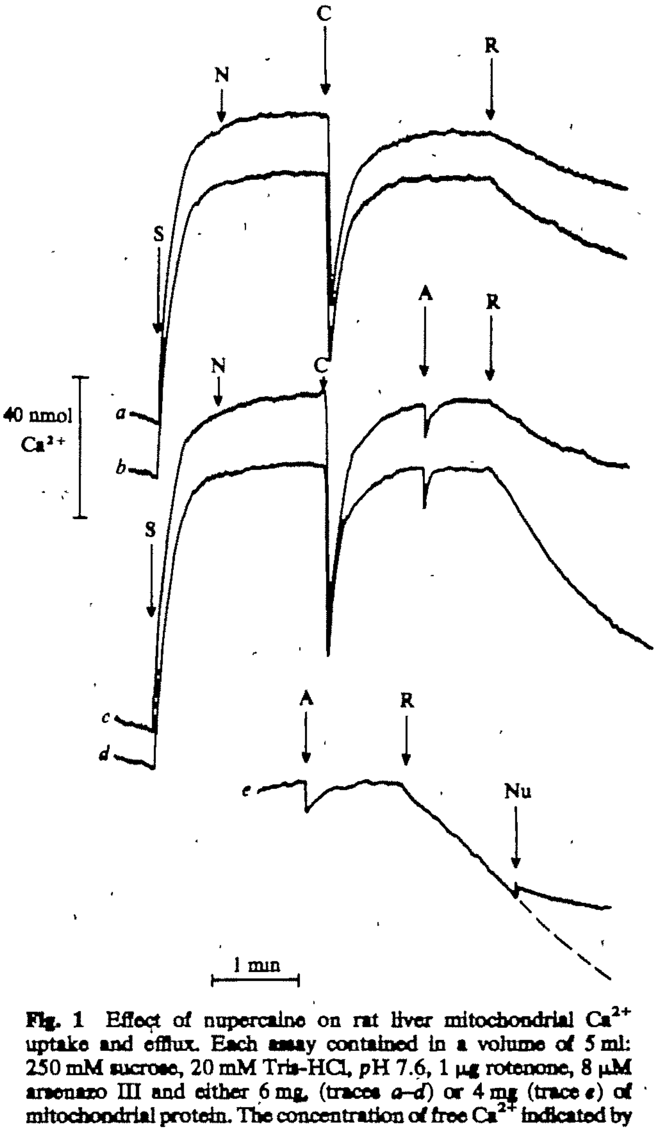

Fig. 1 Effect of nupercaine on rat liver mitochondrial Ca^{2+} uptake and efflux. Each assay contained in a volume of 5 ml: 250 mM sucrose, 20 mM Tris-HCl, pH 7.6, 1 μg rotenone, 8 μM arsenazo III and either 6 mg (traces *a–d*) or 4 mg (trace *e*) of mitochondrial protein. The concentration of free Ca^{2+} indicated by arsenazo III was measured using the absorbance difference 685–665 nm. A downward deflection of the trace indicates increasing extra-mitochondrial Ca^{2+}. The temperature was 30 °C. For traces *a–d*, succinate (12.5 μmol) was added at S, calcium chloride (50 nmol) at C and ruthenium red (6 nmol) at R. For traces *a* and *c*, 0.3 μmol nupercaine was added at N and for traces *c* and *d*, 12.5 μmol acetoacetic acid (Li salt) was added at A. For trace *e*, the experimental technique was exactly as for trace *d* up to the addition of 12.5 μmol acetoacetate at A. 4 nmol ruthenium red was added at R and 0.5 μmol nupercaine at Nu. The initial part of the trace is omitted for clarity. The dotted line represents the course of Ca^{2+} efflux in the absence of nupercaine.

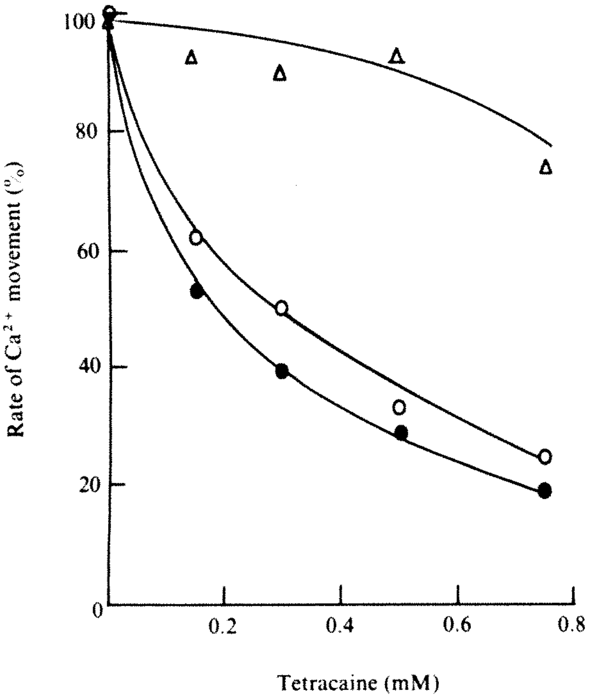

Fig. 2 Effects of tetracaine on Ca^{2+} uptake and efflux. The experimental procedure was the same as for Fig. 1, traces *a–d*, except that for measurement of the rate of Ca^{2+} uptake, the time axis was expanded 2.5×. Each assay contained 8 mg rat liver mitochondrial protein. △, Initial rate of Ca^{2+} uptake after the addition of 50 nmol Ca^{2+}; ○, ●, initial rate of efflux after addition of ruthenium red. In ●, 12.5 μmol acetoacetate was added 1 min before ruthenium red.

ruthenium red causes a slow release of Ca^{2+} from the mitochondrial matrix[7,8] which is enhanced by substrates such as acetoacetate, which cause oxidation of intra-mitochondrial NADH (ref. 10). In mitochondria from other tissues, such as heart and brain[8,9], the ruthenium red-insensitive release is dependent on Na^+ ions. We report here, using mitochondria from both rat liver and brain, that nupercaine and tetracaine, at concentrations which do not inhibit Ca^{2+} uptake, cause considerable inhibition of the ruthenium red-insensitive Ca^{2+} efflux observed in energised conditions.

Rat liver mitochondria were prepared as previously described[11], except that 0.5 mM EGTA was included in the homogenisation and first-wash media. Non-synaptosomal rat brain mitochondria were isolated by the method of Garbus[12] in a medium containing 320 mM sucrose, 5 mM HEPES–KOH, *p*H 7.6, and 0.5 mM EDTA, followed by purification on a discontinuous Ficoll gradient as described by Nicholls[9]. Ca^{2+} uptake and output were measured using arsenazo III as an extra-mitochondrial Ca^{2+} indicator[13] in an Aminco-Chance dual wavelength spectrophotometer equipped with a stirred cuvette. The overall response time was approximately 0.5 s.

Figure 1*b* shows the standard procedure used for our experiments with rat liver mitochondria. The addition of succinate causes the rapid uptake of free Ca^{2+} from the medium (40 nmol) plus Ca^{2+} which has leaked out of the mitochondria before the initiation of respiration. After 2 min the mitochondria were loaded with a further 50 nmol Ca^{2+} (as $CaCl_2$). Then, after a further 2 min, uptake was inhibited by the addition of 1 nmol ruthenium red per mg protein. This resulted in a slow Ca^{2+} efflux, as described previously[7,8]. In Fig. 1*a*, 60 μM nupercaine was added before Ca^{2+}. It can be seen that this has no effect on the kinetics of Ca^{2+} loading, but the subsequent efflux rate after ruthenium red addition is inhibited to approximately 50% of the control rate. When 2.5 mM acetoacetate is present for 1 min before ruthenium red, the initial rate of efflux is approximately doubled (Fig. 1*b*, *d*). Figure 1*c* shows that this higher rate is also 50% inhibited by 60 μM nupercaine.

Although in these experiments the anaesthetic was in contact with the mitochondria for $3\frac{1}{4}$ min, preincubation is not necessary. Figure 1*e* shows that the addition of 100 μM nupercaine after efflux has been initiated causes an essentially immediate inhibition of Ca^{2+} output. This result seems to rule out the possibility that effects due to preservation of mitochondrial integrity are involved in the inhibition of efflux, as these would presumably require the presence of the anaesthetic throughout the experiment.

Figure 2 summarises data for tetracaine, including its effect on the velocity of Ca^{2+} uptake. It can be seen that concentrations of the anaesthetic which cause up to 70% inhibition of efflux have essentially no effect on uptake, although at higher concentrations uptake is impaired to some extent. Preliminary observations with butacaine suggest that it behaves similarly to tetracaine, but there is a less clear distinction between its effects on uptake and efflux. The concentration of butacaine required for 50% inhibition of efflux is ~0.8 mM, compared with 0.2 mM for tetracaine and 0.06 mM for nupercaine.

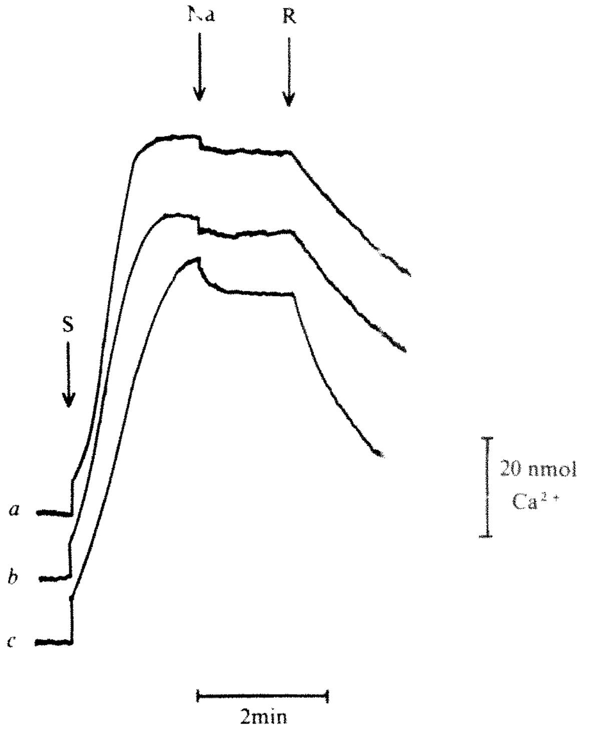

Fig. 3 Effects of nupercaine and tetracaine on rat brain mitochondrial Ca^{2+} uptake and efflux. Each assay contained in 5 ml: 250 mM sucrose, 20 mM Tris-HCl, *p*H 7.6, 1 μg rotenone, 1 mM potassium phosphate, *p*H 7.6, 6 μM arsenazo III, 12 μM free Ca^{2+} (measured with a Ca^{2+}-sensitive electrode) and 2.4 mg mitchondrial protein. For all traces: S indicates the addition of 12.5 μmol succinate (K^+ salt); Na, 25 μmol NaCl; R, 3 nmol ruthenium red. In addition, experiment *a* contained 1.1 μmol nupercaine and *b* 2.5 μmol tetracaine, both added 30 s before succinate. Other conditions were as for Fig. 1.

Figure 3 shows the effects of nupercaine and tetracaine on Ca^{2+} transport by rat brain mitochondria. In the conditions of this experiment, both compounds produce a considerable stimulation of uptake, an almost complete inhibition of the Na^+-induced efflux and a 50% inhibition of the rate of Ca^{2+} release subsequent to ruthenium red addition. The nature of the stimulation of uptake is not clear, but one possibility is a decrease in Ca^{2+} cycling during uptake.

Because the local anaesthetics used in this study all carry a positive charge, it might be expected that when they bind to a membrane they would reduce its passive permeability to cations[14]. Also, local anaesthetics have been shown to compete with Ca^{2+} for binding sites in the mitochondrial membrane[15]. It is rather surprising, therefore, that, at low concentrations, nupercaine and tetracaine inhibit Ca^{2+} efflux and have little effect on, or stimulate, Ca^{2+} uptake. Also, we have found that the rapid efflux of Ca^{2+} brought about by collapse of the membrane potential by uncouplers or antimycin A (ref. 7) is not affected by tetracaine, either in the presence or absence of ruthenium red. The inhibition of efflux in energised conditions thus seems to be a relatively specific effect, and provides further evidence for the view that the route for Ca^{2+} efflux from mitochondria is different from that for uptake. It is clearly a possibility that if mitochondria are involved in the regulation of cytosolic Ca^{2+} concentration, then this concentration might be perturbed by the application of nupercaine or tetracaine. Such a perturbation of external Ca^{2+} concentration would not be readily observed in the experimental conditions shown in Fig. 1, as even in the absence of nupercaine, measurements with a Ca^{2+}-sensitive electrode show that the mitochondria reduce the free external Ca^{2+} concentration to approximately 1 μM. If nupercaine stimulated the uptake of some, or even all, of this residual Ca^{2+}, the resulting change in absorbance of arsenazo III would be very small. It has, however, been observed[16] that the application of 0.1–1 mM tetracaine to perfused liver blocks both glucagon and cyclic AMP stimulated gluconeogenesis and Ca^{2+} release into the perfusate.

We thank CIBA for the nupercaine.

Gene fusion during the evolution of the tryptophan operon in Enterobacteriaceae

THE genes of tryptophan biosynthesis are organised differently in various species of microorganisms[1]. In several organisms it seems that gene fusions have joined functionally distinct polypeptide chains into single bifunctional proteins. Here we present our analysis of one example of a possible gene fusion and an attempt to deduce the sequence of events responsible.

The two initial reactions specific to the tryptophan pathway

$$\text{chorismate} + \text{L-glutamine} \xrightarrow{Mg^{2+}} \text{anthranilate} + \text{pyruvate} + \text{glutamate} \quad (1)$$

$$\text{anthranilate} + \text{5-phosphoribosylpyrophosphate} \xrightarrow{Mg^{2+}} N\text{-(5'-phosphoribosyl)anthranilate} + \text{pyrophosphate} \quad (2)$$

are catalysed by the enzymes anthranilate synthetase (AS) and anthranilate-5-phosphoribosylpyrophosphate phosphoribosyl transferase (PRT) respectively. In many bacterial genera[1,2], AS is an enzyme complex containing two non-identical polypeptides, components I and II[3]. Component I alone can convert chorismate to anthranilate using NH_3 but not L-glutamine as the amino donor. Component II contributes glutamine amido transferase (GAT) activity to the complex, thus conferring the ability to use L-glutamine as the amino donor[2]. While the size of AS component I is fairly uniform in bacteria[2], at least two different forms of component II have been observed. In *Escherichia coli*[4], and *Salmonella typhimurium*[5] it has a molecular weight of about 65,000 and has two distinct enzymatic capabilities: it provides the GAT activity for reaction (1) when complexed with component I, and catalyses reaction (2), the PRT reaction, whether in the complex or not. In *Serratia marcescens* a small polypeptide with a molecular weight of 21,000 contributes the GAT activity to AS[6–8], but a separate polypeptide with a molecular weight of 45,000[8,9] has PRT activity.

The two enzyme activities of AS component II of *E. coli* and *S. typhimurium* are associated with different segments of the polypeptide chain. Genetic studies indicate that the GAT activity resides in the N-terminal third of the molecule while PRT activity is associated with the remainder of the polypeptide chain[10–12]. Mild proteolytic digestion of intact component I–component II complexes of *E. coli* or *S. typhimurium*[8,13] produces a component II fragment of molecular weight 23,000 which retains GAT activity but lacks PRT activity. Li *et al.*[8] have found extensive amino acid sequence homology at the N-terminal end of these component II fragments of *E. coli* and *S. typhimurium* and the functionally homologous intact component II GAT polypeptide of *S. marcescens.* This suggests that the GAT region of the bifunctional component II polypeptides of *E. coli* and *S. typhimurium* and the smaller GAT subunit of *S. marcescens* share the same evolutionary origin and lends direct support to the idea that the bifunctional component II polypeptides of *E. coli* and *S. typhimurium* arose by fusion of two separate genes, one coding for a GAT and a second coding for PRT[5,8,11,14].

In *E. coli* all the genes of tryptophan biosynthesis are organised as an operon with the structural gene for AS component I (*trpE*) closest to the promoter/operator region[15]. *trpE* is followed by the structural gene for AS component II (*trpD*), with the genetic region specifying the GAT portion of the polypeptide (*trpG*) closest to *trpE*[8]. In order to indicate the two domains of the structural gene for the bifunctional component II polypeptide of *E. coli,* we shall designate it *trp*(*G*)*D* (ref. 1). In *S. marcescens*, the evidence for the organisation of the genes of tryptophan biosynthesis as an operon is indirect[9]. In particular, it was uncertain whether the structural gene for the GAT subunit of AS, *trpG*, lies adjacent to *trpD*, the PRT structural gene, or whether it is unlinked to the remaining genes of the operon, as in *Bacillus subtilis*, where AS component II also seems to provide GAT function for *p*-aminobenzoate synthesis[16,17].

We have recently characterised a cloned DNA fragment containing the regulatory region and first structural gene, *trpE*, of the *S. marcescens trp* operon[18]. DNA sequence analysis revealed that the fragment also contains the sequence coding for the first nine amino acids at the N-terminus of AS component II, confirming that *trpG* lies adjacent to *trpE* in the *trp* operon of *S. marcescens*[18]. Here we report the cloning of a different DNA fragment containing all the structural genes of the *S. marcescens trp* operon with the exception of *trpA*. A functional and structural analysis of this DNA fragment established that the gene order at the promoter proximal end of the *S. marcescens trp* operon (*trpE–trpG–trpD*) is analogous to the arrangement in *E. coli.* We have determined the DNA nucleotide sequence of the *trpG–trpD* punctuation region in *S. marcescens* and of the analogous region of the fused *trp*(*G*)*D* gene of *E. coli.* A comparison of the two sequences reveals extensive homology

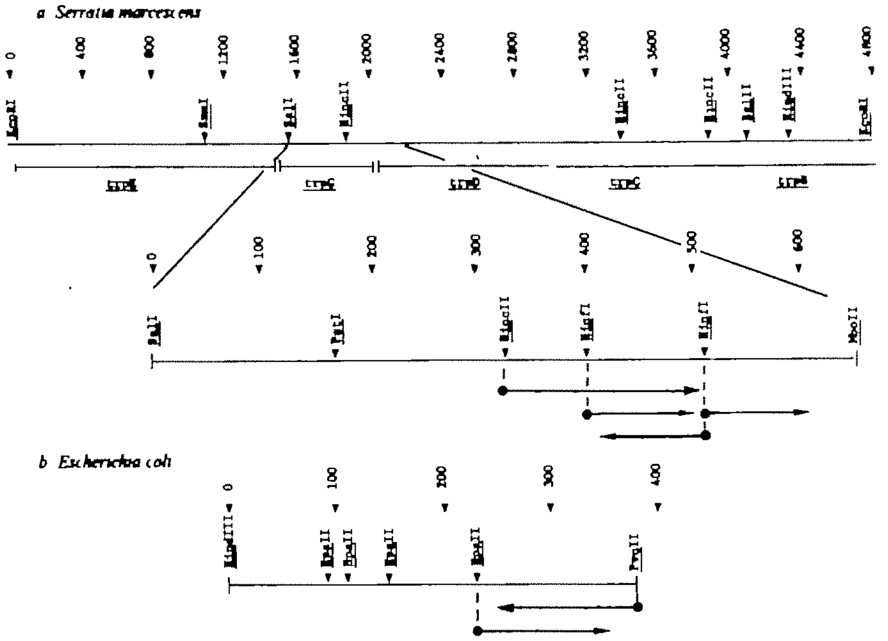

Fig. 1 *a*, Restriction map of a cloned fragment containing *S. marcescens trpEDCB*. Chromosomal DNA of *S. marcescens* was prepared by the method of Saito and Miura[37]. 10 μg of chromosomal DNA and 5 μg of pBR322 DNA were digested with *Eco*RI, phenol extracted, ethanol precipitated and resuspended in 250 μl of ligation buffer (60 mM Tris-HCl, *p*H 7.6, 10 mM $MgCl_2$, 10 mM dithiothreitol, 1 mM ATP). The mixture was incubated in the presence of T4 DNA ligase for 2 h at 13 °C. Ligation was stopped by ethanol precipitation and the pellet resuspended in 100 μl TE-buffer (10 mM Tris-HCl, *p*H 7.9, 0.1 mM EDTA). 20 μl were used to transform *E. coli* strain JA 221(C600 $r^- m^+ \Delta trpE5$ *leu recA*, obtained from J. Carbon) to prototrophy. Trp^+ transformants were screened for plasmid content. Plasmid pGM6 was recovered from such a transformant. It carries a single 4,800 base pair *Eco*RI insert. A restriction map of this insert is shown in the top portion of (*a*). The direction of the transcription is from left to right. The approximate location of the various *trp* genes is indicated underneath; the gene order in the dotted portion of the line has not been determined with certainty. The bottom portion of (*a*) shows an expanded restriction map of the DNA region containing the *trpG–trpD* interconnecting/intercistronic region. The arrows indicate the direction and length of sequencing runs, *b*, Restriction map of a DNA fragment from *E. coli* containing the *trpG–trpD* interconnecting region. *E. coli trpPOLED* DNA was isolated from plasmid pVH153[20]. The arrows underneath the restriction map indicate the length and direction of sequencing runs.

within the *trpG* and *trpD* structural genes, but considerable divergence in the *trpG–trpD* junction region. How the two sequences may be evolutionary related will be considered.

Chromosomal DNA of *Serratia marcescens*, obtained from wild-type strain SM6, was restricted with endonuclease *Eco*RI and the cleavage products were inserted into the *Eco*RI site of plasmid pBR322[19]. Plasmids carrying the initial portion of the *S. marcescens trp* operon were selected from the ligation mixture by their ability to transform an *E. coli* recipient strain which carries a deletion of most of *trpE* to tryptophan independence (see legend to Fig. 1 for experimental details). Plasmids pGM6, isolated from such a transformant, carries a single *Eco*RI insert of approximately 5,000 base pairs, whose restriction map appears in the top portion of Fig. 1*a*. pGM6 yields Trp^+ transformants with *trpE*, *trpD*, *trpC* and *trpB* but not *trpA* mutant recipients. Thus pGM6 carries most of the *S. marcescens trp* operon. The physical location and orientation of the *S. marcescens trp* genes on the *Eco*RI insert was determined by subcloning portions of the insert using various restriction enzymes. One such plasmid, pGM63, carries the 1,500-base pair *Eco*RI–*Sal*I segment from the left hand end of the *Eco*RI fragment shown in Fig. 1(ref. 18). This DNA fragment contains the entire *trpE* gene from *S. marcescens*[18]. The *Eco*RI site precedes the start of *trpE* by 20 base pairs, while the *Sal*I site is located approximately 30 base pairs beyond the *trpE–trpG* boundary[18]. Neither pGM6 nor pGM63 contains the promoter/operator region of the *S. marcescens trp* operon. Therefore, in both plasmids transcription of the *trp* genes must originate at a pBR322 promoter. The orientation of the insert is the same in both plasmids. Transcription is towards the region determining tetracycline resistance and away from the region determining ampicillin resistance[19].

We estimated the location of the *trpG–trpD* boundary of *S. marcescens* on the basis of the molecular weight of 21,000 for the *trpG* gene product[4,5]. The end of *trpG* and the presumed *trpG–trpD* intercistronic region was predicted to be approximately 500 base pairs from the *Sal*I site in the initial portion of *trpG*. A detailed restriction map of this DNA segment is shown in the bottom portion of Fig. 1*a*. DNA sequence analysis was performed with DNA fragments labelled at either the *Hin*fI sites (positions 400 and 520) or the *Hin*cII site (position 330) as outlined in Fig. 1*a*.

The analogous region of the *E. coli trp* operon is contained on plasmid pVH153[20]. This plasmid carries *E. coli trpPOLE*(*G*)*D* on a 4.7 megadalton *Eco*RI fragment from $\lambda trpED_{10}$ inserted into the *Eco*RI site in pVH51 (mini-ColE1[21]). A *Hin*dIII site is located in the initial portion of *E. coli trp*(*G*)*D*[22]. The exact location of this restriction site, 275 base pairs from the *trpE–trp*(*G*)*D* punctuation region, has been determined by DNA sequence analysis (C. Yanofsky *et al.*, in preparation). The molecular weight of 23,000 for the amino terminal proteolytic fragment of *E. coli* AS component II[6] is very similar to that of component II from *S. marcescens* (21,000). By analogy to the *S. marcescens trp* operon we would therefore expect the *trpG-D* junction region in *E. coli* to be located approximately 300 base pairs downstream from the *Hin*dIII site. A restriction map of the corresponding DNA segment is shown in Fig. 1*b*. DNA sequence analysis was performed with DNA fragments labelled at either the *Hpa*II site at position 225 or the *Pvu*II site at position 380 as indicated in Fig. 1*b*. The nucleotide sequence of this DNA segment is presented in Fig. 2 along with the sequence of the analogous region from *S. marcescens*.

The *S. marcescens* nucleotide sequence contains a potential ATG translation initiation codon at positions 88–90 (Fig. 2). The predicted amino acid sequence from this site is identical to the previously determined amino acid sequence at the N-terminal end of *S. marcescens* PRT[23]. This confirms our assumption that *trpD* follows *trpG* in the *S. marcescens trp* operon. The amino acid sequence at the C-terminal end of *S. marcescens* AS component II was determined by carboxypeptidase digestion of purified component II. The results [(Trp, Ala)-Leu-Ala-Lys-COOH] indicate that the TAA at positions 70–72 is used as the translation stop codon. In *S. marcescens trpG* and *trpD* are thus separated by an untranslated region 16 base pairs in length. Six contiguous mucleotides within this region (TAAGGA) are homologous to the 3′ terminus of *E. coli* 16S rRNA[24], a feature common to many prokaryotic ribosome binding sites[25].

The nucleotide and amino acid sequences preceding and following the segment corresponding to the *trpG–trpD* intercistronic region have been extensively conserved between *S. marcescens* and *E. coli*. Twenty of 23 amino acids in the *trpG* portion and 16 of 22 amino acids in the *trpD* portion are identical (Fig. 2). Several changes at the nucleotide level (eight in *trpG*; seven in *trpD*) are not reflected at the amino acid level. In contrast to this, sequence conservation is not immediately apparent in the *trpG–trpD* intercistronic region (Fig. 2). In *E. coli* 15 nucleotides are present in this DNA segment compared with 16 in *S. marcescens*; as a consequence the coding sequences of the *E. coli trpG* and *trpD* segments are in phase. This, together with the absence of translational stop and start signals (also there is no obvious sequence homology to the 3′ end of 16S ribosomal RNA), accounts for the production of a 'fused' *trp*(*G*)*D* polypeptide in *E. coli*.

The marked similarity between the two sequences suggests a common origin. This implies that at least once during the evolution of the *trp* genes in the Enterobacteriaceae a gene fusion or gene separation event occurred in the *trpG–trpD* region. Bonner *et al.*[26] have suggested that evolutionary development progresses from independent proteins through multimeric enzymes to fused gene products. Alternatively, as pointed out by Largen *et al.*[27], a fusion event involving ancestral *trpG* and *trpD* genes may have occurred before the appearance of the Entrobacteriaceae, in which case the separate *trpG* and *trpD* genes of *S. marcescens* would represent the result of a subsequent separation of the fused genes. Although the first possibility seems more plausible, the available evidence does not allow us to rule out the alternative route.

Fig. 2 Nucleotide sequence of the DNA region surrounding the *trpG–trpD* interconnecting/intercistronic region in *E. coli* and *S. marcescens*. The two sequences have been lined up in the *trpG* and *trpD* portion to show homologies. The predicted amino acid sequence is indicated between the DNA sequences. A split amino acid sequence indicates that the nucleotide sequence predicts a different amino acid for the two organisms at that position. The predicted amino acid sequence following the ATG codon at position 88–90 of the *S. marcescens* nucleotide sequence corresponds exactly to the previously determined amino acid sequence at the N-terminal end of *S. marcescens* PRT[23]. The C-terminal residues of *S. marcescens* AS component II were determined by carboxypeptidase A and B digestions of the purified protein[8,33]. The sequential appearance of Lys, Ala, Leu, and Trp served to identify the TAA at position 70–72 as the translation stop codon. The message punctuation signals in the *S. marcescens trpG–D* intercistronic region (translation stop and start codons, homologies to the 3′ end of *E. coli* 16S rRNA) are underlined. DNA sequence analysis was performed by the method of Maxam and Gilbert[36]. Details of this and related procedures such as isolation of plasmid DNA and DNA restriction fragments, restriction site mapping, phosphatase treatment, polynucleotide kinase reactions and agarose and polyacrylamide gel electrophoresis are given in refs 38, 39.

Fig. 3 Hypothetical sequence of events involved in the conversion of the separate *trpG* and *trpD* genes of *S. marcescens* into the single fused *trp*(*G*)*D* gene of *E. coli*. In reality the postulated fusion event would have taken place in a common ancestor of both organisms which may have been similar to *S. marcescens* in its nucleotide sequence.

If the fused *trp*(*G*)*D* arrangement of *E. coli* were ancestral to the *S. marcescens* gene order, the conversion of the first Lys codon of Fig. 3 to a stop codon would probably suffice to give separate, active, *trpG* and *trpD* polypeptides. The present day *trpG–trpD* interconnecting nucleotide sequence of *E. coli* may in fact have weak ribosome binding and translation initiation activity. Mutational studies suggest that there is a translation reinitiation site within *E. coli trp*(*G*)*D* which can produce a polypeptide with PRT activity[10,12]. In addition, as mentioned earlier, the polypeptide segment specified by the *trpG* portion of *trp*(*G*)*D* of *E. coli* has GAT activity. Thus separation could occur without loss of activity. Subsequent mutational changes could improve the efficiency of ribosome binding to the initiation region of *trpD* and consequently increase the yield of PRT.

One of several hypothetical sequences of events that would result in the formation of the fused *E. coli trp*(*G*)*D* gene from the separate *trpG* and *trpD* genes of *S. marcescens* is illustrated in Fig. 3. In a first step a single mutational event removes the *trpG* translational stop signal, allowing out-of-phase translation into the adjacent *trpD*. Both *trpG* and *trpD* are still expressed but out-of-phase translation probably would reduce production of the *trpD* polypeptide. Deletion of a single base pair in the immediately adjacent region (step 2) results in the formation of a fused polypeptide whose two functional domains would be held together by an 'immature' connector region. However, the fused gene retains the efficient parental *trpD* ribosome binding site and thus might produce both a fused *trp*(*G*)*D* polypeptide and a *trpD* polypeptide. Subsequent mutations in the intercistronic region could inactivate the ribosome binding site and/or introduce functionally acceptable amino acids (step 3) and alter the ATG start sequence (step 4). Three synonymous codon changes and two substitutions resulting in amino acid replacements (step 5) would then give the *E. coli* sequence. The *E. coli* connector region presumably does not interfere with the correct folding of the two functional domains of the fused polypeptide. As can be seen from the last line of Fig. 3, the overall sequence of events would not involve extensive base changes in the intercistronic region. This sequence of events neglects the fact that the fusion event would have taken place in an unknown *Serratia*-like ancestor which differed from *S. marcescens* in its nucleotide sequence. It is obvious that a single deletion event could more simply fuse the adjacent *G* and *D* genes. Perhaps the connector region of *E. coli*, in mRNA or protein, has some important unsuspected function.

Gene fusion and separation may have occurred several times in the evolution of the tryptophan genes. In yeast the third and fourth steps of the biosynthetic pathway are catalysed by separate proteins coded for by unlinked genes[28], while in *E. coli* and many other prokaryotes both reactions are catalysed by a single bifunctional polypeptide encoded in a single gene, *trpC*[1,28,29,30]. The converse is found for tryptophan synthetase, where the fungal enzyme consists of a fusion of α and β chain elements[31,32] which are separate polypeptides in *E. coli* and other prokaryotes[33]. The *trpG–trpD* case may be unique in that both the fused and separate states of the genes are found within closely related organisms, where evolutionary divergence apparently has not been significant enough to totally obscure the original fusion event.

If the fusion of genes involved in the same pathway confers a selective advantage, one wonders why in *S. marcescens* the separate *trpG* and *trpD* genes have not been replaced by a fused genetic element, particularly since fusion need involve so few mutational events. It is conceivable that in order for the fusion to become fixed, compensatory mutations must occur elsewhere within *trpG* or *trpD*. In such circumstances, the probability of a successful fusion event would be substantially reduced. Alternatively, *S. marcescens* AS component II may serve as a GAT subunit in *p*-aminobenzoate formation as does AS component II of *B. subtilis*[16,17] and *Acinetobacter calcoaceticus*[34]. Such a dual function of the *trpG* gene product would obviously place severe restrictions on the likelihood that *trpG* would undergo gene fusion.

These studies were supported by grants from the USPHS (GM 09738), the NSF (PCM 77-24333) and the American Heart Association. G.M. was a postdoctoral fellow supported by the Swiss National Science Foundation. C.Y. is a Career Investigator of the American Heart Association. This work was performed in accordance with NIH guidelines on recombinant DNA research.

Specific binding of Mu repressor to DNA

PHAGE MU is a temperate virus of *Escherichia coli* (for reviews see refs 1, 2). The immunity system of Mu has been shown by genetic and physical mapping to lie in the furthest left, 1,000-base-pair restriction fragment of the phage DNA[3-6]. This end of the phage genome is associated with a short (100-base pair) segment of bacterial DNA[4]. The *Hin*dIII-c restriction fragment of Mu (the furthest left 1,000 base pairs[4]) has been cloned into the amplifiable plasmid pMB9 (ref. 7). These recombinant plasmids confer high levels of Mu immunity on their hosts and, when recloned into minicell-producing strains, were shown to produce an additional protein of 25,000 subunit molecular weight in purified minicells[6,7]. This protein is assumed to be the Mu repressor because its production is correlated with immunity to Mu. We report here experiments which show that this protein binds specifically and with high affinity to Mu DNA, as would be expected of the Mu repressor. Furthermore, we demonstrate that the DNA sequence (operator) to which the Mu repressor binds is located on the same *Hin*dIII-c restriction fragment of Mu DNA as the repressor gene.

In these studies DNA binding was assayed using the unpurified crude extract of labelled minicells as a source of repressor. These extracts contain so few other labelled proteins that the only purification required is the removal of the plasmid DNA. Extracts of minicells derived from strains transformed

Table 1 Specific binding of the temperature-sensitive Mu repressor to Mu DNA

Crude lysate of repressor	DNA-bound repressor (fractions 5/6 (6/7*))	Unaggregated repressor (fraction 9/10)
−DNA	<1%	31%
+Mu DNA	13%	26%
+D108 DNA	<1%	31%
+λ DNA	<1%	31%
+25 DNA	14%*	23%
+p5D7 DNA	<1%	7%

The crude lysate of minicells was prepared as described in the legend to Fig. 1, and the top fraction of the high salt gradient used as the source of repressor. Aliquots were mixed with buffer IV or buffer IV plus 20 μg Mu, λ or D108 DNA, or 2.0 μg linearised plasmid 25 DNA or plasmid p5D7 DNA. The DNA concentrations were such that approximately equal numbers of DNA molecules were added to each binding mix. The binding mixture was incubated and run on gels as described in Fig. 1 legend. The fractions collected were assayed for proteins and DNA as before. Autoradiographs of the SDS-acrylamide gels run on gradients with repressor alone, repressor + Mu, repressor + D108 and repressor + λ DNA are shown in Fig. 1. The autoradiographs were scanned and the peaks of repressor weighed and normalised as described in Fig. 2 legend. The per cent of total repressor recovered from fractions 5+6, or 6+7 (DNA-bound repressor), and from fractions 9+10 (unaggregated repressor) is shown. Due to the noise in the system, repressor in amounts <1% of the total repressor in the gradient would not be detectable by scanning; Mu, D108, λ and plasmid p5D7 DNA sediment to fractions 5 and 6 in the gradients, whereas plasmid 25 DNA linearised by digestion with *Hin*dIII sediments to fractions 6 and 7 in these conditions.

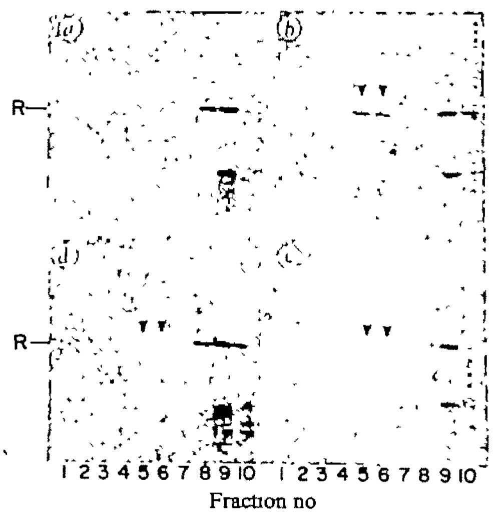

Fig. 1 Comparison of repressor binding to Mu, D108 and λ DNA ^{35}S-Methionine-labelled minicells purified (according to the procedure described by Zipser *et al*[6]) from χ1274/pMB9-mu *cI*ts62 *Hin*dIII-c 25 (frozen in 10 mM Tris, *p*H 8, 5 mM EDTA, 10% sucrose, 0.05 M NaCl) were lysed in the following manner The minicells were thawed slowly on ice, and NaCl and lysozyme were added to final concentrations of 0.3 M NaCl and 150 μg ml^{-1} lysozyme. After 1 h on ice, the minicells were frozen in a dry ice–ethanol bath and thawed on ice, five times. Triton X-100 was added to a final concentration of 0.33% (v/v), and the minicells were incubated for 20 min at 0 °C. The crude lysate (150 μl total volume) was centrifuged at 20,000 r.p.m. in a Beckman SW 60 rotor to remove cell debris and insoluble proteins. The supernatant was adjusted to 0.6 M NaCl and layered onto a 5 ml 5–20% sucrose in buffer IV (10 mM Tris, *p*H 8, 1 mM EDTA, 0.1 mM dithiothreitol, 50 μg ml^{-1} bovine serum albumin) gradient containing 0.6 M NaCl. The gradient was then centrifuged for 2 h at 45,000 r.p.m. (4 °C) in the Beckman SW 50.1 rotor, and 10 0.5-ml fractions were collected from the bottom of the gradient. Sedimentation through high salt was done to eliminate variability in the binding assay due to repressor binding to endogenous DNA In these conditions, the repressor and other labelled proteins remain at the top of the gradient, whereas endogeneous DNA moves to the middle of the gradient. The top fraction was used as the source of repressor in the binding assay. Samples (0.1 ml) of the top fraction were mixed with buffer IV or buffer IV plus 20 μg DNA (Mu, D108 or λ), and adjusted to 0.2 M NaCl. The binding mixtures were incubated for 30 min at 0 °C and then layered onto 5 ml 5–20% sucrose in buffer IV gradients containing 0.05 M NaCl. The gradients were centrifuged for 2 h at 45,000 r.p.m. (4 °C) in a Beckman SW 50.1 rotor, and 10 0 5-ml fractions were collected from the bottom of each gradient. Samples from each fraction were subjected to electrophoresis on 17.5% SDS–polyacrylamide gels. The gels were autoradiographed to assay for labelled proteins. Samples from the gradient fractions were also subjected to electrophoresis on 1% agarose gels. These gels were stained with ethidium bromide and photographed under UV light to assay for DNA Autoradiographs of the SDS-polyacrylamide gels run on gradients with *a*, repressor alone; *b*, repressor plus Mu DNA; *c*, repressor plus D108 DNA; and *d*, repressor plus λ DNA are shown above. The arrow labelled R indicates the position of the repressor band on the gels The vertical arrows indicate the position of the DNA in the gradients. Mu and λ DNA were prepared from lysogens carrying Mu *cI*ts62 and λ *cI*857 S7, respectively, by the procedure of Kahmann[12] D108 was prepared in a similar manner, except that purification of phage was done after infection of strain 783 (Thi$^-$, Trp$^-$, su$^+$) with wild-type D108.

with plasmids carrying the Mu repressor gene were mixed with unlabelled DNA and then sedimented through sucrose gradients[8,9]. To assay repressor, samples from each fraction of the gradients were subjected to electrophoresis on SDS-polyacrylamide gels, and the amount of repressor determined from autoradiographs of these gels. The position of the DNA in the gradient is determined from ethidium bromide-stained agarose gels run on each gradient fraction.

The specificity of Mu repressor is demonstrated in Fig. 1 and Table 1. When a repressor extract without DNA is sedimented through a gradient, the repressor, as well as other labelled proteins, remain near the top of the gradient. When the same extract is used with Mu DNA, a significant fraction of the repressor sediments with the DNA, but the position of other labelled proteins remains unchanged. If equal amounts of DNA from D108, a phage heteroimmune to Mu, or from phage λ are used, only trace amounts of Mu repressor are bound.

When the binding was carried out at 0.1 M rather than 0.2 M NaCl, some repressor was associated with D108, but less than the amount associated with Mu DNA. More repressor was found in the fractions between the DNA peak and the top of the gradient with D108 DNA than was found with Mu DNA, suggesting that the repressor was dissociating from D108 DNA as the DNA sedimented through the gradient. This indicates that although repressor binds tightly to Mu DNA, it has some affinity for other DNAs at lower salt concentrations.

Increasing the salt concentration in the binding reaction from 0.1 to 0.3 M NaCl had little effect on the amount of repressor bound to Mu DNA, but increasing it to 0.6 M NaCl eliminated repressor binding to Mu DNA. Binding was also not detected when both the binding mixture and the gradient contained 0.2 M NaCl.

Phage D108 is closely related, but heteroimmune, to phage Mu[10]. Heteroduplex analysis of D108 and Mu shows a total nonhomology of 6% between the two phages, the largest region of nonhomology (3%) being in the left end of the phages[10], where the repressor maps. As D108 does not bind Mu repressor, the operator must be nonhomologous and could be in the left end of the phage genome also. This would be similar to the situation found with bacteriophage λ, where the operators to which the λ repressor binds are located close to the repressor gene[8,11]. This might mean that the Mu operator is also on the cloned *Hin*dIII-c fragment that carries the repressor gene.

To test this possibility DNA of plasmid 25 (the same plasmid used to synthesise repressor) was used in the binding assay. As shown in Fig. 2, in the same conditions which gave specific binding to Mu DNA, the repressor binds to linearised plasmid 25, but not to linearised pMB9 DNA. Furthermore, the repressor does not bind to DNA of plasmid p5D7 (a recombinant plasmid constructed by the terminal transferase tailing method in a fashion analogous to that of plasmid 25 but inserting yeast genes instead of Mu DNA). This argues against the possibility that the repressor binds to the AT-rich regions created during cloning (see Table 1). Three other plasmids (36, 42 and 54 (ref. 7)) which were constructed in the same manner as plasmid 25 and which carry the same *Hin*dIII fragment of Mu *cI*ts62, also show specific binding of the Mu repressor. Thus, an operator to which the Mu repressor binds, is located in the furthest left 1,000 base pairs of the Mu genome.

The crude repressor preparations used for these studies contain varying amounts of inactive repressor (repressor which cannot bind to operator-containing DNA). The amount of

Table 2 Binding of the temperature-sensitive Mu repressor to varying amounts of DNA

Crude lysate of repressor	DNA-bound repressor (fractions 6/7)	Unaggregated repressor (fractions 9/10)
−DNA	<1%	48%
+0.1 μg 25 DNA	28%	44%
+0.5 μg 25 DNA	55%	47%
+2.5 μg 25 DNA	81%	38%
+12.5 μg 25 DNA	62%	35%
+0.5 μg pMB9 DNA	9%	49%

A crude lysate of minicells was prepared as described in Fig. 1 legend. Aliquots of the top fraction of the high salt gradient were mixed with buffer IV, or buffer IV plus varying amounts of linearised plasmid 25 DNA or 0.5 μg linearised plasmid pMB9 DNA, and adjusted to 0.2 M NaCl. Binding mixtures were incubated and run on gradients as before. The fractions collected were assayed for proteins and DNA as described in Fig. 1 legend. Autoradiographs of the acrylamide gels were scanned for the repressor band and the peaks weighed and normalised as described in Fig. 2 legend. The per cent of total repressor recovered in fractions 6+7 (DNA-bound repressor) and in fractions 9+10 (unaggregated repressor) is shown above. Due to the noise in the system, repressor in amounts <1% of the total would not be detectable by scanning. The DNA sediments to fractions 6 and 7 in these conditions.

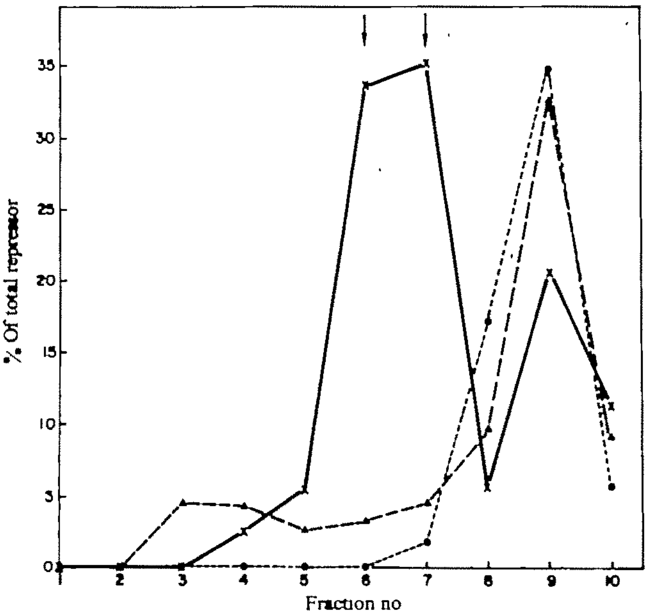

Fig. 2 Comparison of repressor binding to plasmid 25 and pMB9 DNA. A crude lysate of minicells was prepared as described in the legend to Fig. 1. As before, the top fraction of the high salt gradient was used as the source of repressor. Aliquots were mixed with buffer IV or buffer IV plus 2.5μg of linearised plasmid 25 or pMB9 DNA, and adjusted to 0.2 M NaCl. The binding mixture was incubated and run on gradients as described in Fig. 1 legend. The fractions collected were assayed for proteins and DNA as before. The repressor band in autoradiographs of the acrylamide gels were scanned using a Joyce, Loebl densitometer (Chromoscan Mk. II.). The peaks were cut out and weighed to determine the amount of repressor in each fraction. To normalise the amount of repressor in each fraction, samples of the binding mixtures before sedimentation were subjected to electrophoresis on 17.5% SDS–polyacrylamide gels. Autoradiographs of these gels were scanned for the repressor band and the peaks cut out and weighed. The amount of repressor in the control was multiplied by dilution factors to determine the amount of repressor in each binding mix. As an equal amount of the repressor preparation was used for each binding mixture, an average of the amount of repressor in the controls was used to normalise the amount of repressor in fractions of the gradients. The per cent of the total repressor recovered in fractions of gradients with *a*, repressor alone (●), *b*, repressor plus plasmid 25 DNA (×), and *c*, repressor plus pMB9 DNA (△) is shown. The vertical arrows indicate the position of DNA in the gradients. DNA of both plasmid 25 and pMB9 was digested with the restriction enzyme *Hin*dIII (Bethesda Research Labs) which cleaves both DNAs once, making linear molecules. Uncut plasmid 25 also shows binding of the repressor, however, two peaks of bound repressor are detected, corresponding to DNA in the monomer and dimer covalently closed circular forms. In these conditions the dimer DNA sediments further down the gradient than the monomer form. Plasmid 25 and pMB9 were purified from strain χ1274 (*E. coli* K12, Thi^-, Thr^-, Leu^-, $LacY^-$, $MalA^-$, MtL^-, Xyl^-, Ara^-, Gal^-, Str A, ton A, λ^R, azi, Min^-, su^+) according to the procedure of Clewell[13].

repressor found in the top fraction of the gradients did not decrease significantly with increasing amounts of DNA (Table 2). The amount of inactive repressor in any one preparation increased with the storage time of minicell preparations before use.

As shown in Table 2, both the amount of DNA-bound repressor and the overall amount of repressor recovered increase with increasing concentrations of plasmid 25 DNA, except at very high concentrations of DNA. Similarly, more repressor was recovered when pMB9 DNA was added to the same preparation, than was recovered after sedimenting the preparation alone. In this case, however, the repressor was not associated with pMB9 DNA, but was spread throughout the gradient (Fig. 2). This suggests that the active repressor proteins will bind to each other, if not bound to DNA, forming aggregates which sediment rapidly in the gradient. Thus, if the repressor extract is sedimented without added DNA, much of the active repressor goes to the bottom of the gradient.

This repressor–repressor interaction must be weaker than repressor–DNA binding, as any DNA added to the repressor seems to inhibit aggregate formation. As the repressor dissociates from non-operator-containing DNA (that is, pMB9) during sedimentation, however, it will begin to form repressor–repressor aggregates, and this repressor is detected throughout the gradient. Repressor binding to operator-containing DNA (plasmid 25 DNA) is tight, so that very little repressor dissociates from the DNA during sedimentation and no aggregation of the repressor occurs. This finding is consistent with the observation that there is a decrease in the amount of total repressor recovered in binding assays carried out at 0.3 M rather than 0.1 M NaCl. The decrease in recovery is more dramatic with D108 or pMB9 DNA than with Mu or plasmid 25 DNA.

Further characterisation of the nature of the binding of Mu repressor to Mu DNA (and repressor–repressor interaction) requires purification of significant amounts of repressor protein. This is feasible because large quantities of repressor can be made in strains carrying plasmid 25 (or similar recombinant plasmids), and crude DNA binding assays (like that described above) allow easy detection of active repressor during purification.

Surface and inside volumes in globular proteins

MEASUREMENTS of the surface area accessible to solvent provide a convenient definition of the surface and the inside volumes in proteins of known X-ray structure. The study of the accessibility to solvent of amino acid residues in several proteins[1–3] has confirmed the early observation that polar residues are found mostly on the surface and non-polar residues mostly inside globular protein structures. But the accessibility shows systematic variations with the molecular weight, because of the change in surface to volume ratio. Experimental data[4] indicate that the accessible surface area A (in Å^2) of monomeric globular proteins follows the law[5,6]:

$$A = 11.1\, M^{2/3} \qquad (1)$$

which implies that the mean accessible surface area per residues decreases like $M^{-1/3}$ (where M is molecular weight) with increasing M, from about 68 Å^2 for proteins of 6,000 molecular weight to 38 Å^2 for proteins of 35,000 molecular weight. Thus, the accessibility to solvent is not a characteristic of the amino acids.

We made histograms of the accessible surface areas of residues in a sample of 22 proteins, and found that the number n_B of buried residues, defined as having less than a given accessible surface area A_m, varies with the total number n of residues in the

0028-0836/79/0277—0491$01 00

polypeptide chain according to:

$$n^{1/3} - n_B^{1/3} = k \tag{2}$$

where k depends only on A_m. Completely buried residues (zero accessible surface area) are few: 4 in pancreatic trypsin inhibitor (58 residues), 40 in carboxypeptidase A (307 residues). Better statistics are obtained by choosing $A_m = 10$ to 20 Å^2, which amounts to consider as buried residues which have one or two atoms in contact with the solvent. With $A_m = 20$ Å^2, the average value and standard deviation of k are 1.62 ± 0.13. The geometrical significance of equation (2) is apparent in Fig. 1: k represents the thickness of the surface layer made of residues in contact with the solvent. While the hard sphere model of globular proteins, first presented by Fisher[7], is in formal agreement with equations (1) and (2), the fit only implies that the gross geometrical properties of globular proteins (surface and volume) are those of a set of solid bodies which deviate in similar ways from a spherical shape. This is not true of subunits in oligomeric proteins: the subunits of tetrameric lactate dehydrogenase[4] and glyceraldehyde-3-phosphate dehydrogenase have much larger accessible surface areas and fewer buried residues than expected from equations (1) and (2).

Table 1 gives the amino acid composition of our sample of buried and accessible residues. The buried residues make up the protein inside; 56% are Leu, Ile, Val, Ala, or Gly, another 22% are Phe, Ser, Thr or Cys, and 22% are of the 11 other types. The protein surface has a much more regular amino acid composition than the inside: non-polar residues are by no means absent, even though Asn, Asp, Glu, Gln, Lys and Arg constitute 40% of the accessible residues. The ratio f of the molar fractions of each amino acid in the two samples is of particular interest. It represents the partition coefficient of this amino acid between the surface and inside volumes. Consequently, $\Delta G_t = RT \ln f$ may be taken as the free energy of transfer from the inside to the surface. Though the exact value of f depends on the choice of A_m made in defining buried residues, the effect is small: reducing A_m from 20 Å^2 to 10 Å^2 changes the free energies by no more than their statistical standard deviation of 0.1–0.2 kcal mol^{-1}. Thus f and ΔG_t are characteristic of the amino acids in globular proteins.

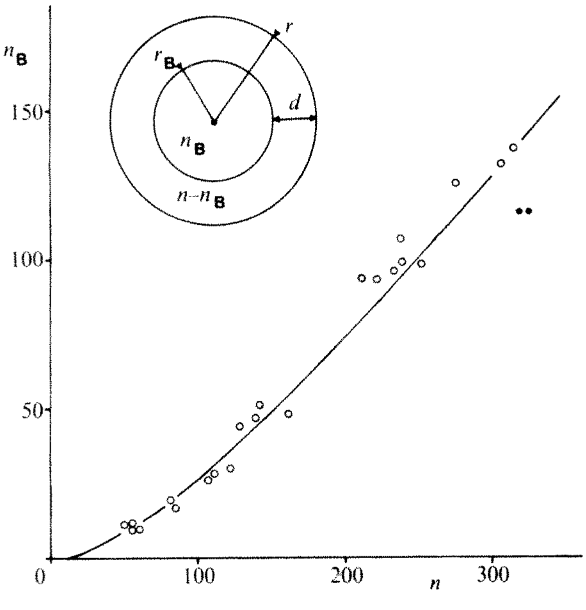

Fig. 1 Buried residues in globular proteins. The accessible surface areas of individual residues are calculated according to Lee and Richards[1] using a computer program of M. Levitt. The atomic coordinates are obtained from the Protein Data Bank, Cambridge, UK. The following 22 protein structures are used here and in Table 1: insulin, ferredoxin, rubredoxin, pancreatic trypsin inhibitor, high potential iron protein, cytochrome b_5, parvalbumin, cytochrome c_2, ribonuclease S, hen lysozyme, staphylococcus nuclease, flavodoxin, phage T4 lysozyme, papain, trypsin, concanavalin A, elastase, α-chymotrypsin, carbonic anhydrase B, substilisin, carboxypeptidase A, thermolysin. The number n_B of residues with less than $A_m = 20$ Å^2 of accessible surface area is plotted against the total number n of residues in the polypeptide chain (open circles). Filled circles represent the subunits of lactate dehydrogenase and glyceraldehyde -3-phosphate dehydrogenase. The insert represents the protein as made of two concentric spheres, the volumes of which are proportional to n and n_B; the radii are proportional to $n^{1/3}$ and $n_B^{1/3}$, and therefore k is proportional to the thickness d of the surface layer, made of $n - n_B$ accessible residues. For the 22 proteins: $A_m = 0$ Å^2, $k = 3.0 \pm 0.4$ (s.d.), $d = 9.6$ Å; $A_m = 10$ Å^2, $k = 2.0 \pm 0.2$, $d = 6.4$ Å, $A_m = 20$ Å^2, $k = 1.62 \pm 0.13$, $d = 5.2$ Å. The solid line is calculated from equation (2) with $k = 1.62$.

Table 1 Amino acid composition of the inside and surface

Residue	Molar fraction Buried	Accessible	Free energy (kcal mol^{-1}) f	ΔG_t	ΔG_h
Leu	11.7	4.8	2.4	0.5	1.8
Val	12.9	4.5	2.9	0.6	1.5
Ile	8.6	2.8	3.1	0.7	
Phe	5.1	2.4	2.2	0.5	2.5
Cys	4.1	0.9	4.6	0.9	
Met	1.9	1.0	1.9	0.4	1.3
Ala	11.2	6.6	1.7	0.3	0.5
Gly	11.8	6.7	1.8	0.3	0.0
Trp	2.2	1.4	1.6	0.3	3.4
Ser	8.0	9.4	0.8	−0.1	−0.3
Thr	4.9	7.0	0.7	−0.2	0.4
His	2.0	2.5	0.8	−0.1	0.5
Tyr	2.6	5.1	0.5	−0.4	2.3
Pro	2.7	4.8	0.6	−0.3	
Asn	2.9	6.7	0.4	−0.5	
Asp	2.9	7.7	0.4	−0.6	
Gln	1.6	5.2	0.3	−0.7	
Glu	1.8	5.7	0.3	−0.7	
Arg	0.5	4.5	0.1	−1.4	
Lys	0.5	10.3	0.05	−1.8	

Molar fractions (%) of the 20 amino acids in samples of 2,001 buried residues (less than 20 Å^2 accessible surface area) and 3,220 accessible residues (more than 20 Å^2); f is the ratio of the buried/accessible molar fractions; $\Delta G_t = RT \ln f$. ΔG_h is the free energy of transfer from an organic solvent to water[8]. Cys residues with a free −SH group are few in the sample; our data are more representative of substituted −SH groups (disulphides, metal adducts or thioethers).

In a protein of n residues, the most probable fraction g of buried residues of one type, say valine, is easily calculated from the data of Table 1:

$$g = \frac{f n_B}{n - n_B + f n_B} \tag{3}$$

where n_B is given by equation (2). Thus, the fraction of valines which are buried increases from 0.4 to 0.7 when the chain length increases from 60 to 300 residues, while it remains less than 0.1 for lysines.

Chothia[3] has noted that the average accessibility of residues in proteins is not correlated to the free energies ΔG_h of transfer from an organic solvent to water, measured by Nozaki and Tanford[8]. This is seen clearly in Table 1: ΔG_t is governed by the presence or absence of oxygen and nitrogen atoms in the side chain[1,3]. These polar atoms must find hydrogen bond partners when the residue is buried, a stringent requirement except for Ser and Thr residues, the hydroxyl group of which can easily form a hydrogen bond to adjacent main chain carboxyl groups[9]. Proline appearas as polar; its imino nitrogen cannot participate in normal main chain hydrogen bonds and behaves as a part of the side chain.

Dimeric association of band 3 in the erythrocyte membrane demonstrated by protein diffusion measurements

BAND 3, a major constituent of the human erythrocyte membrane, comprises a class of membrane-spanning proteins which are implicated in anion and possibly other transport functions[1–4]. Various observations indicate that band 3 proteins may exist as dimers in the membrane[5–9]. The most direct indication has been obtained from chemical cross-linking experiments. The band 3 dimer is an early product of various cross-linking reactions[7], and the particular case of cross-linking by oxidative disulphide bridge formation results in almost quantitative dimerisation of band 3 (ref. 8). However, cross-linking experiments are in general inconclusive for they do not indicate whether a successful cross-linkage reflects a naturally occurring stable complex, or is the result of collisions between independent proteins which rapidly diffuse over small distances. In the recent elegant studies of Kiehm and Ji[9], rapid photochemical cross-linking was achieved by photolysing with a millisecond flash. Whilst these experiments undoubtedly provide the best evidence so far obtained for the existence of the band 3 dimer, they still leave some doubts concerning the possibility of collision-induced crosslinks. These can only be ruled out if the mean time between collisions is shown to be much longer than the lifetime of the flash-induced reactive species. The latter time was assumed to be short (of the order of 1 ms) on the basis of solution studies but was not measured in the experimental conditions. The collision frequency is a function of the local lateral diffusion coefficient. Band 3 diffusion over distances $>1\ \mu m$ seems to be slow in the erythrocyte membrane[10,11], but as discussed elsewhere[12], this may reflect restrictions to long range diffusion and does not rule out the possibility of more rapid local diffusion. If the local diffusion coefficient is in the range 10^{-9} to $10^{-10}\ cm^2\ s^{-1}$, the mean time between collisions is also of the order of 1 ms (ref. 9). A lateral diffusion coefficient in this range is consistent with the rotational diffusion of band 3 (ref. 12). Here we present a new physical approach to determining the self-association of band 3, based on the measurement of rotational diffusion. The rotational diffusion coefficient of an intrinsic membrane protein is strongly dependent on the diameter of its cross-section in the plane of the membrane. We show that cross-linking band 3 into dimers produces no observable decrease in the rotational diffusion coefficient of band 3 in the membrane. We therefore conclude that the dimer pre-exists in the membrane and is not a product of the cross-linking reaction following random collisions.

In the present experiments, the rotation of band 3 was measured by observing the flash-induced transient dichroism of a triplet probe, as previously described[12,13]. However, band 3 was labelled with eosin maleimide instead of the eosin isothiocyanate previously used; essentially similar results are obtained with either probe. Dimerisation of band 3 in the membrane was achieved by copper–phenanthroline-catalysed oxidation of cytoplasmic sulphhydryl residues to form disulphide bridges, as described by Steck[8].

Figure 1 shows the result of the cross-linking reaction as visualised by SDS-polyacrylamide gel electrophoresis. Band 3 has disappeared from its normal position in the gel, moving to a new band with a molecular weight of approximately 180,000, corresponding to the band 3 dimer. This result is identical to that reported by Steck[8].

The rotational mobility of band 3 in the cross-linked membranes was measured and compared with that of untreated controls. The transient dichroism measurements were analysed by calculating the absorption anisotropy $r(t)$ given by

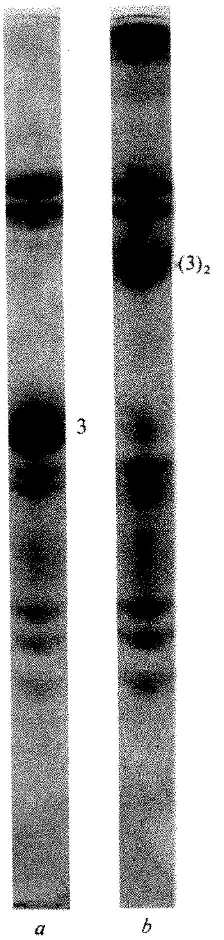

Fig. 1 Dimerisation of band 3 by oxidative disulphide bridge formation. Intact human erythrocytes were labelled with eosin-5-maleimide as described previously for other eosin derivatives[12,13,19], except that incubation was for 1 h at room temperature. These conditions yield approximately 1 molecule of bound eosin per band 3 monomer. Ghosts were prepared by hypotonic lysis[12] and given a final wash in 5 mM sodium phosphate, *p*H 8.0. They were allowed to react for 1 h at room temperature with one volume of *o*-phenanthroline (200 μM) and copper sulphate (40 μM) in the same buffer. The reaction was ended by the addition of 30 volumes 1 mM EDTA and 5 mM sodium phosphate, *p*H 8.0, and by a further wash in 5 mM sodium phosphate, *p*H 7.4. The control sample was subjected to the same procedures but without the addition of the copper–phenanthrolin reagent. Ghosts were then dissolved for electrophoresis and run on cylindrical 4% polyacrylamide gels in 0.2% SDS as described by Steck[8]. 3 and $(3)_2$ denote the positions of the band 3 monomer and dimer, respectively. Gel *a*, control; gel *b*, cross-linked ghosts.

$$r(t)=\frac{A_{\parallel}(t)-A_{\perp}(t)}{A_{\parallel}(t)+2A_{\perp}(t)} \qquad (1)$$

where $A_{\parallel}(t)$ and $A_{\perp}(t)$ are, respectively, the absorbance changes at time t after the flash for light polarised parallel and perpendicular with respect to the polarisation of the exciting flash. Figure 2 shows the time dependence of r for dimerised and untreated band 3. It is clear that the shapes of the two curves are virtually identical.

As discussed elsewhere[12,14], the predicted form of $r(t)$ for a protein which rotates only about the axis normal to the plane of the membrane is

$$r(t)=A_1\exp(-D_{\parallel}t)+A_2\exp(-4D_{\parallel}t)+A_3 \qquad (2)$$

where $D_{\parallel}$ is the rotational diffusion coefficient and A_1, A_2, A_3 are constants. To make a quantitative comparison of the cross-linked and control samples, we made a least-mean-square fit of

0028–0836/79/0277—0493$01.00

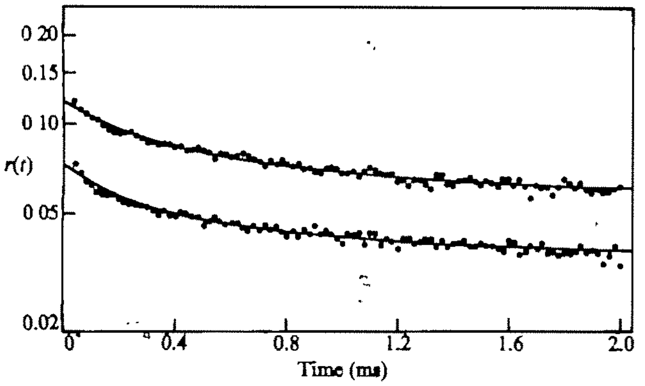

Fig. 2 Time dependence of the absorption anisotropy for untreated and cross-linked erythrocyte membranes. Flash-induced transient dichroism of the eosin probe was measured using a flash photolysis apparatus which is described in detail elsewhere[13]. The sample was excited at 540 nm by a linearly polarised flash of duration 1–2 µs. Absorbance changes arising from ground state depletion were measured at 520 nm. Upper curve, untreated control; lower curve, cross-linked as described in the legend to Fig. 1. Experimental points were obtained by averaging 32 signals. The solid lines were obtained by fitting the data to equation (2). For illustrative purposes the two curves have been artificially separated by a vertical displacement of the lower curve by 20%. Otherwise the data almost exactly superimpose. Measurements were made at 37 °C in 5 mM phosphate buffer, *p*H 7.4, under argon.

the data to equation (2). In this way we obtain $D_{\parallel} = 1{,}296 \pm 99\ \mathrm{s}^{-1}$ and $1{,}492 \pm 202\ \mathrm{s}^{-1}$ for the control and cross-linked membranes, respectively.

If we regard band 3 as a cylinder of radius a immersed to a depth h in the membrane, then the coefficient for rotational diffusion about the membrane normal is given by[15]

$$D_{\parallel} = (kT)/(4\pi a^2 h\eta) \qquad (3)$$

where η is the membrane viscosity. Thus, the rotational diffusion coefficient depends on the square of the radius of the rotating species. Assuming that dimerisation increases the radius of the particle by a factor of 1.5–2, we thus expect a two- to fourfold difference in $D_{\parallel}$ between the monomer and the dimer. As we fail to observe any decrease in $D_{\parallel}$ following cross-linking, we conclude that the band 3 dimer exists as a stable complex in the erythrocyte membrane independent of chemical cross-linking.

A possible objection to this conclusion is that the cytoplasmic portion of band 3 on which the reactive SH-group is located[16], is attached by a flexible linkage to the major part of the protein whose rotation we observe. Hence, cross-linking in this position might not change the rotation of band 3 monomers. However, Ross and McConnell have reported[17] that a spin label bound to the same SH-group is 'immobilised' (on the conventional electron spin resonance time scale). This strongly suggests that the cytoplasmic fragment is rigidly attached to the bulk of the protein and is not an independently rotating entity.

It should also be pointed out that cross-sectional shapes of band 3 could in principle be devised which would considerably reduce the expected change in $D_{\parallel}$ on association of monomers into dimers. Because we could detect a change in radius with cross-linking as small as 15%, we consider this a rather improbable explanation of our data. Taken together with the earlier chemical studies, there can be little doubt that band 3 does exist as a stable dimer within the human erythrocyte ghost membrane. However, further association of band 3 dimers among themselves or with other integral membrane proteins such as the major sialoglycoprotein are not ruled out.

The functional significance of the band 3 dimer is unclear. As the major part of band 3 is the anion transport system[1,2,18], it is tempting to speculate that the anion channel is formed at the interface between the two subunits of the dimer. However, inhibition studies with disulphonic acid stilbene inhibitors[18] and eosin maleimide[19] show that about one inhibitor bound per band 3 monomer is required for total inhibition of anion transport. This suggests that there are two anion binding sites per channel, if there is only one channel per band 3 dimer. Alternatively, one half of the inhibitor molecules could be bound to nonspecific sites on the protein.

Thus, the experiments reported here demonstrate how rotational diffusion measurements can be used to detect stable oligomeric complexes of proteins within biological membranes. We anticipate that the approach may be extended to other membrane proteins, for example, the (Mg^{2+}, Ca^{2+})ATPase of the sarcoplasmic reticulum, where the possibility of self-association is now under consideration[20,21].

Binders for the journal are also available at £8.00 (UK), US$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

matters arising

Coesite and stishovite in the Vredefort, South Africa

RECENTLY I have been involved in tectonophysical research in the Witwatersrand collar sequence of the Vredefort dome, concentrating on microfabric studies in the collar quartzites with particular reference to the shock metamorphic microstructures found in some of these rocks. These shock microstructures include planar features, crystallographically controlled cleavage, crystallographically controlled faults and mosaic extinction. Other microstructures include extreme undulose extinction and deformation bands.

Planar features are the most widely accepted indicators of shock deformation and in the Vredefort collar quartzites they occur as decorated, planar discontinuities parallel to crystallographic planes in the quartz. The crystallographic orientation of planar features can be used to estimate the magnitude of shock pressures sustained by the rock sample[1-3], and has been used with considerable success at the Charlevoix and Slate Islands structures[2,3]. The technique involves measuring the orientation of planar features in 20 to 30 grains in a sample, classifying each grain on the basis of its planar feature content[1], and assigning to each a pressure value calculated from experimental data[2,3]. The shock pressure in the rock is then calculated as the mean of shock pressures in individual grains.

Samples from the Witwatersrand collar (Fig. 1) have been used in the type of analysis described above. Shock estimates range from 59 to 148 kbar. A diagram showing estimated shock pressure as a function of distance from the core–collar contact is shown in Fig. 2 in which the curve of best fit is nonlinear and given by

$$P_{\mathrm{sh}} = 145.47D^{-0.39}$$

where P_{sh} is the estimated shock pressure and D is the distance from the core-collar contact. There is a strongly evident decrease in shock pressure away from the contact.

Many of the shock microstructures in the Lower Witwatersrand quartzites, however, have been recovered and recrystallised. The amount of recrystallisation increases towards the core, from minor recrystallisation away from the core (in which minor amounts of new quartz occur along planar features and grain boundaries) through major recrystallisation (where a large percentage of the rock is recrystallised with only relict primary grains), so that the Hospital Hill quartzites are completely recrystallised. Minor recrystallisation extends to the outermost quartzites of the collar. Major recrystallisation, however, occurs in a zone[4] which has the same shape as, but is not as extensive as, the limit of contact metamorphism in the collar (which is shown in Fig. 1), so that it is probable that recrystallisation in the quartzites is a result of the thermal metamorphism which produced the contact metamorphic metapelites in the collar.

Stöffler[5] has demonstrated that after their formation, coesite and stishovite are metastable and susceptible to reversion during thermal metamorphism. Certainly one would expect that large amounts of high pressure quartz polymorphs would be found in the lowermost Witwatersrand rocks (those closest to the core) since this is where the shock pressures are greatest (Fig. 2). However, as Martini has shown, none are found; samples from the Hospital Hill quartzite examined by Martini (those from Marra 395, Fig. 1 and Vlakspruit 1180, which is off Fig. 1 to the south-west) are barren. However, Martini did find coesite and stishovite at Weltevrede 167 and coesite at Ospan 238 which are high up in the Witwatersrand sequence (Fig. 1).

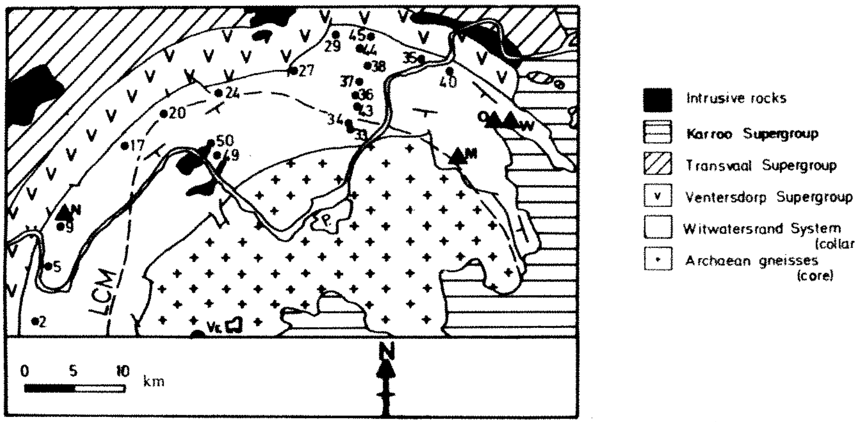

Fig. 1 A simplified geological map of the Vredefort dome (modified after Bisschoff[6]) showing the limit of metamorphism in the collar (LCM)[6] and the localities of samples used in the shock pressure analysis (dots). The approximate localities of farms on which Martini[7] took samples are shown as triangles where W is Weltevrede 167, O is Ospan 238, M is Marra 395 and N is Nooitgedacht 508. The towns of Parys (P) and Vredefort (Vr) are also shown.

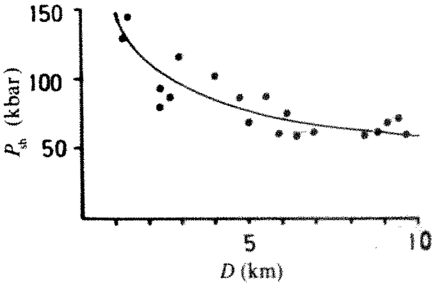

Fig. 2 A plot of estimated shock pressure (P_{sh}) against distance from the core–collar contact (D) for samples from the Vredefort collar sequence.

I suggest, therefore, that no polymorphs are found in the lowermost collar rocks because they were affected by the post-shock, metamorphic overprint. Only those rocks not strongly affected by metamorphism and/or recrystallisation (that is, the rocks further from the core) would retain their high pressure polymorphs of quartz.

The sample which Martini took on Nooitgedacht 508 (Fig. 1) is, however, barren. This is well outside the thermal aureole and does not fit comfortably into the model outlined above. My sample from Nooitgedacht 508 (sample 9, Fig. 1) shows evidence of minor amounts of recrystallisation along planar features; this indicates that these rocks were very slightly affected by the metamorphism. This may account for the lack of high pressure minerals in these rocks.

This work was supported by the CSIR and the South African National Geodynamics Project.

5. Stöffler, D. *J. geophys. Res.* **76**, 5474–5488 (1971).
6. Bisschoff, A. A. *Trans. geol. Soc. S. Afr.* **76**, 27–52 (1973).
7. Martini, J. E. J. *Nature* **272**, 715 (1978).

MARTINI REPLIES—The microfabric investigations conducted by Lilly are of great interest as they not only confirm the very high pressure conditions having characterised the Vredefort Dome event, but also give a geographical distribution of these conditions. However, the number of samples analysed for coesite and stishovite is statistically not representative and at this stage it is not possible to demonstrate any clear field relationship between the distribution of high-pressure silica polymorphs and the extent of Lilly's metamorphic zone. On theoretical grounds, I agree that metamorphism must account at least in part for the absence of these minerals, but a much more detailed investigation is needed to clarify this aspect. Other factors may be also responsible for the absence of coesite and stishovite.

The post-shock metamorphism described by Lilly results probably from the high temperature of the rocks immediately before impact. Due to the great magnitude of this event, deep portions of the continental crust must have been shattered, at depths where temperatures attained several hundred degrees. In the Vredefort Dome these deep portions are represented by the lower part of the Witwatersrand Supergroup and by the granitic core, that is those rocks in which the post-shock metamorphism is developed.

After the quick uplift which occurred immediately after impact, rocks brought very close to the surface cooled down rapidly. This part is now eroded. In contrast, rocks which remained at a depth of several hundred metres or more, which presumably constitute the present-day outcrops, remained warm long enough to allow for the recrystallisation of shock metamorphism textures and reversal of coesite and stishovite into quartz. This probably explains the post-shock metamorphism, which in fact has been initiated before the impact.

Expected shapes of asteroids

FUJIWARA *et al.*[1] have demonstrated experimentally that random breakage of basalt blocks to simulate asteroid formation produces a predominance of what the sedimentary petrologists call blade-shaped fragments; rod-like and sphere-like fragments tended not to be produced. These results agree well with a theoretical analysis[2] of the random breakage situation in which very simple probabilistic methods were used to estimate the formation of the four basic Zingg shapes (disks, spheres, blades and rods). It was proposed that, with an attainable 10% accuracy of dimensional resolution, random breakage of an isotropic rock material would yield 72% blade shapes, 27% tetragonal shapes (rods and disks) and 1% equiaxed shapes (spheres). The sphere value agrees well with the Fujiwara *et al.* results but the theoretical estimation did not allow rods and disks to be separated. It is possible that the experiments[1] produced several disk particles which were judged to be blades. In some earlier experiments Drake[3] examined various rock types; basalts and other aphanitic rocks produced approximately the same number of spheres as predicted by the theory but the number of blades was greater, at the expense of rods and disks; as Fujiwara *et al.* have also found.

NATURE

We invite applications for 1979 Writing Fellowships and Sabbaticals at *Nature.*

Writing Fellowships

There will be opportunities for two or three scientists or journalists to travel on our behalf and write feature articles and news stories based on their experiences. We see these fellowships as a means of extending the coverage of our news pages.

Sabbaticals

We shall also have two or three vacancies for scientists with a particular interest in editing or writing to spend a short period working with the *Nature* staff.

For further details and application forms please write to:

The Editor, *Nature,*
4 Little Essex Street, London WC2R 3LF

stating which scheme you are interested in.

Pharmacia Peristaltic Pump P-3

A compact pump electronically controlled for constant liquid flows in chromatography and gradient formation

You can

- obtain three different flow rates at the same time through the three individually tensioned pumping channels
- change tubes in seconds with the snap-in cassette
- forget about pulsation thanks to the large driven rollers
- rely on a constant motor speed, electronically compensated for load and temperature
- use any flow rate between 0.6 and 400 ml/h per channel with the same gear box
- reverse the flow instantly
- push for maximum flow and clear pump lines rapidly

NEW!

JOURNAL OF ANALYTICAL AND APPLIED PYROLYSIS

Editors: H. L. C. Meuzelaar
Flammability Research Center
University of Utah
391 South Chipeta Way,
Research Park,
Salt Lake City, UT 84108, U.S.A.

H.-R. Schulten
Institut für Physikalische Chemie
der Universität Bonn
5300 BONN
Wegelerstrasse 12
G.F.R.

Associate Editor: C. E. R. Jones, 36 Green Lane, Redhill, Surrey RH1 2DF, U.K.

This new international journal brings together, in one source, qualitative and quantitative results relating to:

- Controlled thermal degradation and pyrolysis of technical and biological macromolecules;
- Environmental, geochemical, biological and medical applications of analytical pyrolysis;
- Basic studies in high temperature chemistry, reaction kinetics and pyrolysis mechanisms;
- Pyrolysis investigations of energy related problems, fingerprinting of fossil and synthetic fuels, coal extraction and liquefaction products.

The scope will include items such as the following:

1. Fundamental investigations of pyrolysis processes by chemical, physical and physico-chemical methods.
2. Structural analysis and fingerprinting of synthetic and natural polymers or products of high molecular weight.
3. Technical developments and new instrumentation for pyrolysis techniques in combination with chromatographic or spectrometric methods, with special attention to automation, optimization and standardization.
4. Computer handling and processing of pyrolysis data.

Pyrolysis is applied in a wide range of disciplines. This journal will therefore be of value to scientists in such diverse fields as: polymer science, forensic science, soil science, geochemistry, environmental analysis, energy production, biochemistry, biology and medicine.

Contributions will be in the form of: original papers, technical reviews, short communications, letters, book reviews and reports of meetings and committees. The language of the journal is English. Prospective authors should contact one of the editors.

Publication Schedule and Subscription Information:

The journal will be published quarterly. The first issue is scheduled to appear in Spring 1979.
1979: Volume 1 (in 4 issues), US $70.75/Dfl. 145.00 including postage

A free sample copy will be sent on request.

Major environmental controversy

B. A. Thrush

The Ozone War. By L. Dotto and H. Schiff. Pp. 342. (Doubleday: New York, 1978.) $10.

THE most interesting environmental controversy in recent years has surrounded the potential effects of supersonic aircraft and of chlorofluoromethanes (CFMs) on the stratospheric ozone which protects the Earth's surface from harmful ultraviolet light. Although the basic mechanism by which oxygen is converted into ozone had been propounded in 1930 by Chapman, the atmosphere had become so much a preserve of meteorologists and atmospheric physicists that, forty years later when it was suggested that the nitrogen oxides in the exhausts from supersonic aircraft would deplete the ozone layer, no-one knew what the natural amounts of nitrogen oxides in the ozone layer were.

In such circumstances, it is hardly surprising that projected fleets of 500 supersonic planes were predicted to produce large depletions of ozone, and that the major Climatic Impact Assessment Program (CIAP) was established in the United States. When CIAP's report appeared in 1975, the problem had largely disappeared because of the paucity of supersonic aircraft and better knowledge of the problem. By now, Molina and Rowland's paper (*Nature*, **249,** 810; 1974) had switched attention to the CFMs, particularly F-11 ($CFCl_3$) and F-12 (CF_2Cl_2) which are extensively used as aerosol propellants, refrigerants and foam-blowing agents. The great stability of these compounds ensures that they are eventually transported up to the stratosphere where their decomposition products will remove ozone. Because the predicted ozone depletions increase slowly to a maximum over a period of 50–100 yr, they would be very hard to detect against the short-term fluctuations in ozone cover; the argument therefore revolved around modelling calculations. To the thriving and vocal industries involved, 'theory' and 'hypothesis' rapidly became pejorative words, although research was soon financed. US Government agencies battled briefly for the 'lead' role. Many scientists joined the bandwagon and the Congressional Record sometimes provided rapid publication for unrefereed work. The public were often confused by contradictory news stories, and (although it is customary to blame the press for seeking scare stories) some scientists provided them willingly, others unwittingly through the difficulty of explaining a complex problem clearly.

This book gives a fascinating insight into the people and organisations who became involved in these controversies. To those accustomed to the more phlegmatic debate of such issues in this country *The Ozone War* may sound an exaggerated title, but many of the participants saw themselves as crusaders against the lack of action or the overreaction by Environmentalists, Industry or Government Agencies, with Congressional Hearings providing a natural sounding board.

The debate calmed down when the National Academy of Sciences (for once not described as 'prestigious' in a North American publication) appointed a panel to examine the CFM problem. Their report in 1976 concluded that release of F-11 and F-12 at the 1973 rates would eventually produce an ozone depletion of 7% with uncertainty limits from 2–20%. Predictably, some saw the upper limit as a cause for immediate action and others saw the lower limit as a reason for delaying action. Surprisingly, the latter have taken heart from recent discoveries which have reduced estimates of ozone depletion by supersonic aircraft and by increased use of nitrogenous fertilizers, despite the concomitant increases in the predicted effects of CFMs.

Surprisingly, there has been no debate on what would be an acceptable ozone depletion, and the potential effects of ozone depletion have received much less attention. A 10% decrease in ozone would increase damaging ultraviolet light by about 20%, probably causing a similar increase in skin cancer. However, such diseases are only responsible for about 1% of cancer deaths, although the figure is increasing rapidly because of the fashion for suntans in recent years. Is excessive sunbathing a health hazard or should we be more concerned about the considerable effect of increased ultraviolet light on phytoplankton? Will ozone depletion affect atmospheric circulation and therefore the climate? Here the answer is that it is probably less than that due to the increased carbon dioxide from burning fossil fuels.

Basically, the aerosol spray provides an easy target for the environmentalist, whereas the other uses of F-11 and F-12 in air conditioners, in insulating foam and in refrigerators require a more careful cost–benefit analysis. Another interesting point to be considered is how far different nations can agree about what is a global problem, as the effects of these compounds are quite independent of where on the Earth's surface they are released.

The history of how the vital processes in atmospheric chemistry were discovered and the rush to join the bandwagon are reminiscent of *The Double Helix* but with a much larger cast and broader setting in which Industry, Government Agencies and individual scientists strive to protect their own interests. The principal events and characters are well described and although one protagonist may not be pleased to see the first measurement of the rate of an important reaction attributed to another, the authors are to be congratulated on producing a highly readable and accurate account of how a major environmental controversy evolved in the United States. There are lessons here for all, particularly for those who wish to know how newspapers can come to publish contradictory or dogmatic reports about an unresolved issue. □

Plant-parasitic nematodes

Ecology of Plant-Parasitic Nematodes. By D. C. Norton. Pp. 268. (Wiley: New York and Chichester, UK, 1978.) £16.95.

THIS book is an introductory account of plant-parasitic nematodes in relation to their environment. It is not an updated version of Wallace's book *Nematode Ecology and Plant Disease,* as the author tackles the subject from, what he terms, a broad ecological viewpoint. Emphasis is placed on the effects of the environment rather than on the disease aspect, and discussions on nematode damage to plants are largely omitted.

The first five chapters cover aspects

of nematode distribution, dispersal, habitats, groupings and communities, and population change. These include some interesting, but all too brief, discussions on the origins and recent past of nematodes, clustering, their means of dissemination, and some methods of analysing nematode communities and populations. It is well accepted that parasitic nematodes are always found associated with all forms of plant life; and, under the heading of habitats, the author mentions their associations with fungi, algae, lichens, mosses and higher plants. An introduction to population changes is presented in which seasonal changes, growth patterns, r and k selection, and sex ratios are discussed.

In the following two chapters the author deals with the soil environment: in the first of these, he discusses basic soil principles referring frequently to the interrelationships between soil factors; and in the second, he discusses the effects of physical and chemical soil changes on the nematodes, the section on effects of soil fertility is of particular interest to plant nematologists. The remainder of the book is concerned with survival, biological control, and interactions between nematodes and with other organisms. The final chapter is a disappointingly short account of the effects of agricultural practices on nematode populations, although the author acknowledges that the influence of cultural practices on nematodes has not received the attention it deserves.

There are errors throughout the book which could have been avoided—for example, the use of some defunct nematode nomenclature. Dr Norton has summarised much of the relevant literature in tabular form rather than discussing it in the text; even so these lists are not exhaustive. Most of the literature cited and the majority of the discussions relate to the ecology of nematodes in the United States. Although these are often relevant to work elsewhere, the book seems to have been written with the North American market in mind.

It is a useful introductory book to plant nematode ecology in which the author has brought together information from ecological disciplines relating to nematodes under one cover. Some interesting ideas are introduced, but it is not a sufficiently in-depth, critical or comprehensive study of the subject to entirely satisfy the needs of the professional nematologist. **John Bridge**

John Bridge is Overseas Plant Nematology Liaison Officer for the Ministry of Overseas Development and a Research Fellow at Imperial College, University of London, UK.

Search for psychological reality

Linguistic Theory and Psychological Reality. By M. Halle, J. Bresnan and G. A. Miller. Pp.329. (MIT Press: Cambridge, Massachusetts, and London, 1978.) £12.25; $17.50.

THE search for psychological reality is on again. Last time the psychologists did the searching with the new toys they did not understand; this time it is the linguists (at least in approach) who are doing the searching and get the reviewer very confused in the process. It is a book without Chomsky, but with his bust on the mantlepiece, in which we start with the acceptance that linguistics is a branch of psychology but come away with the feeling that they mean that psychology is a branch of linguistics. Linguists and psychologists talk together; they write chapters which refer to each other (good editorial work here) but to scarcely anyone else.

We start with a chapter by Bresnan on "A realistic transformational grammar". The largest part of this is devoted to a beautiful linguistic demonstration of how some facts which used to be handled by transformations are now handled in the lexicon. The linguistics is generally judged among the best being produced currently and is very convincing. The 'realistic' in the title is introduced early. She makes the explicit claim that if a grammar is "to represent the knowledge of the language user in any psychologically interesting way" then all the grammatical rules must be realisable in a psychological model. If this is a serious claim then one might think that the best strategy would be to focus first on the types of constraint that psychology might impose. Instead we get the impression that the psychology is an afterthought. A hand reaches out languidly to pluck out a single piece of supporting data or intuition but no more. Thus Bresnan gives us reasons for arriving at passive and short passive forms directly instead of by means of transformations. At the end she notes that one of the other contributors to the volume reports that short passives (for example, the dog was bitten) was acquired before full passives by children. The tone of voice is almost congratulatory—how sensible of the children to realise the correct derivation! Such use of psychological evidence permeates the book.

Wanner and Maratsos give an example of a different kind of model, an Augmented Transition Network (ATN). One of their aims is to parse sentences without recourse to transformations. Strangely, then, we are also told several times that these parsers "are not incompatible with a transformational model of language". Remembering that Bresnan still found transformations necessary, this is reassurring. However, if Brenan's grammar is psychologically realistic and the ATN's have psychological reality doesn't the latter have to be the realisation of the former?

The lexical side of language is no better handled except in a little piece on "The child as a word learner" by Susan Carey. In this she exposes the magnitude of the task of pairing thousands of words with their meanings in a few years. No answers, but a hint of the psychological questions. George Miller has a chapter on the semantic relations among words. This is a development of the ideas he put forward with Johnson-Laird in *Language and Perception* (reviewed in *Nature;* **264,** 124, 1976). Miller makes some tight formal points but his thinking doesn't make as close a contact with psychological issues as the earlier work. Still, this is better than Jackendorf who, like Miller, wants to claim that semantics must derive from a general theory of conceptual structures. This seems a saner view of universality than one which bases it exclusively on language, but Jackendorf effectively turns the relationship around by using linguistic analysis to derive the semantic system from which the cognitive universals should emerge. The effectiveness of his argument may be judged from a nonlinguistic parallel which he describes—"the ability of a dancer to create appropriate dances for given music . . . in such a way that there is substantial interpersonal agreement on how appropriate the translation is." There must be generalisations which mediate the "complex and subtle" expression "determined at least in part along lines laid down by the nature of the organism." (Q.E.D.).

This kind of nativism gets another airing by Halle in a discussion of phonology where a 1971 result of Eimas is cited in support of innate mechanisms of speech analysis. Half-a-dozen or more recent refutations of this view have apparently gone unremarked (see, for example a chapter by Mehler in *Psycholinguistics,* series 2, ed. Morton and Marshall; Elek, 1979). There is a lot of intelligence in this book overall and a review by a linguist might give a much more positive impression but the *and* in the title is disjunctive.

M. Vinogradov, Moscow
T. Vucetic, Split

Scope
The Journal of Plankton Research will publish papers dealing with both zoo- and phytoplankton, in marine, freshwater and brackish environments. The three main topics covered are: (1) the ecology (including model studies) of plankton, including larval and juvenile stages; (2) the physiology (including experimental results) of planktonic organisms; (3) the distribution, life histories and taxonomy of planktonic organisms.

Submission of Manuscripts
Contributions falling within the above scope are invited. Papers will not normally exceed 20 pages in length, although in exceptional cases, longer papers will be considered. Manuscripts (the original and two copies) should be submitted directly to the Executive Editor. Guidance notes for contributors may be obtained from the Production Editor.

Subscription Information
The first quarterly issue of Volume I will appear in Spring 1979.
Subscription prices:
USA, Canada, Central & South America US $65.00
Rest of the world (surface mail) £35.00
Rest of the world (air mail) £39.50

Oxford University Press

A History of Technology

Volumes VI and VII: The Twentieth Century c.1900–c.1950 Parts I and II

Edited by Trevor I. Williams

These two volumes extend the five-volume *History of Technology* edited by Charles Singer, E. J. Holmyard, A. Hall, and Trevor Williams, which covers the period from earliest times to 1900. The same guiding principles that were adopted for the earlier volumes have been retained for these, but greater emphasis has been placed on the economic, social, and political aspects in order to reflect their increasing importance in the twentieth century. Illustrated Volume VI £25, Volume VII £27

Sea-Level Changes

North-west England
during the Flandrian Stage

M. J. Tooley

In 1974 the Board of the International Correlation Programme approved a key project on *Sea-level movements during the last 15,000 years*, and thereby initiated a programme of co-ordinated research into global sea-level movements. The subject of this research monograph is the study of the evidence for, and nature of, sea-level changes in north-west England. £12 *Oxford Research Studies in Geography*

Industrial Geology

Edited by J. L. Knill

These essays provide an introductory survey of applied geology for the more advanced undergraduate or the postgraduate student, those who are teaching geology, and planners concerned with geological resources. The subjects treated are: the energy resource industries; oil and natural gas; coal; mineral development; mineral exploration; the metallogeny of Britain; aggregates, sand, gravel, and constructional stone; cement; groundwater; the construction industry; geological hazards; geology in conservation. £9.50

Kinematic Geometry of Mechanisms

K. H. Hunt

The aim of this book is to explain how modern methods can be brought to bear on the problems of mechanism analysis and synthesis. The first half of the book deals with the conventional kinematic geometry of planar mechanisms; the second half with less familiar subjects, such as the theory of screws, a wide-ranging and important topic which has long been neglected. £35

M

ICE AGES

Solving the Mystery

John Imbrie and Katherine Palmer Imbrie

In 1971 the National Science Foundation organised the CLIMAP project to study changes in the climate of the earth over the past 700,000 years. Out of their analytical work came an exciting by-product: confirmation of the correctness of one of the several theories about what causes ice ages to occur.

This book was written by one of the principal scientists of the CLIMAP group and his daughter, a writer. It presents the recent findings and puts them into perspective. It tells the story of ice ages: what they were like, why they occurred, and when the next one is due.

"It is satisfying that at last we have a work which brings us up to date on a scientific mystery whose solution will literally dictate the future of humanity."
Dr. Stephen H. Schneider, deputy head of the climate project of the National Center for Atmospheric Research.

FLOODS

A Geographical Perspective

Roy C. Ward
Focal Problems in Geography series

This study of major flood problems ranges from the hydrological causes of floods, and their prediction and routing, to a survey of man's response when confronted by serious flooding. Each of the world's major flood-areas is considered, and particular reference is made to floods as geomorphological agents.

M MACMILLAN PRESS

Haematological overkill

The Year in Hematology, 1978. Edited by R. Silber, J. LoBue and A. S. Gordon. Pp. 517. (Plenum Medical: New York and London, 1978.)

ALL the signs are that we are entering a state of literary polycythaemia. For non-clinical readers this means that current scientific writing is suffering from a pathological excess of blood. As well as the increasing number of textbooks and monographs on the subject and a rapidly proliferating series of haematology journals, many of which carry review articles, there are regular review series such as *Clinics in . . .*, *Recent Advances in . . .*, *Topics in . . .*, *Seminars in . . .*, *Progress in . . .*, and many more, all offering minor variations on the same theme. Added to all this the general scientific and medical journals are giving a considerable amount of space to articles on haematological topics, and nearly every international meeting on the subject now insists that authors prepare manuscripts for a published account of the proceedings. Presumably somebody reads all these reviews and the publishing houses and the Inland (and Internal) Revenues (if not the authors) are waxing rich. However, as blood letting rather than transfusion is the more logical approach to the treatment of polycythaemia, surely the appearance of yet another review series in this field must raise serious questions about the value of all this repetitive writing.

The Year in Hematology first appeared in 1977 and on the jacket of the 1978 edition the series is described as offering "a comprehensive overview of the latest findings and trends that have occurred during the last year, critically appraising the most recent observations of normal and abnormal function in the hemopoietic system". A glance at the list of references at the end of each chapter and of their contents indicates that it does no such thing. In fact, this is yet another collection of review articles.

Because of this plethora of activity the editors of new haematological review series must exercise considerable ingenuity in finding topics which have not been covered many times in the previous year or two. In fact, there are one or two subjects which appear in this edition of *The Year in Hematology* which fall into this category, although not many. For example, the interesting chapters on the regulation of the egress of bone marrow cells, thymosin, and the effects of anti-cancer agents on haemopoietic progenitors deal with areas which have not been overexposed recently. On the other hand haemoglobin switching, cytogenetic studies in leukaemia, leukaemia antigens, and recent advances in the treatment of Hodgkin's disease and non-Hodgkin's lymphoma have all figured with monotonous regularity.

With a few exceptions the subjects covered in the 1978 *Year in Hematology* are dealt with thoroughly, referenced adequately and presented clearly. The book is well produced and illustrated. Perhaps it is unfair to judge this series after only two editions but the editors are certainly going to have to use all their imagination to really justify the existence of yet another review series in a field in which the number of 'overviews' seems to be in danger of exceeding the number of original articles which are available to be reviewed. Indeed, the horrid neologism 'overview' seems to be in real danger of taking on a rather different meaning to that which its inventors had in mind!

Green crop fractionation

Leaf Protein and Other Aspects of Fodder Fractionation. By N. W. Pirie. Pp. 183. (Cambridge University Press: Cambridge and London, 1978.) £8.

IMPROVED systems of crop production and utilisation attract world-wide attention. The technique of fractionation to produce high quality foods for humans and simultaneously feeds for farm livestock from fibrous green crops comes into this category. For approaching half a century N. W. Pirie has inspired, with his determination and enthusiasm, much research in both the developing and more developed regions of the world. Students, teachers, scientists and others with a devotion to improving food production, including those with particular interests in fractionation, would do well to read the book and to absorb the vast amount of investigation which has already taken place.

Leaf protein is potentially a most abundant source of protein with a good nutritive value, and temperate and tropical flora examined as sources of extractable protein are numerous. The separation and preparation of good fractionation products is well documented and these can be stored safely to prevent deterioration. A vast amount of qualitative information is already available from the scientific literature and the need now is for more quantitative data: crop and machines used must be thoroughly defined so that the end-products cease to be mysterious. The main challenge now is to assess when the exciting technical potential can be harnessed to provide worthwhile practical systems.

N. W. Pirie has always been interested in the less developed areas of the world and already there is evidence of sub-tropical villagers using leaf protein as food. The expansion of this type of work needs a missionary approach and substantial financial support to act as the catalyst. Adoption of the technique has been slow. At the present time a greater interest seems to exist for exploiting the fractionation technique on a factory scale to produce leaf protein more as a source of pigment for poultry rations than as a source of protein. Some units already exist in Europe and North America and a modest expansion of this use of the technique is likely to occur around the world. Whether as a 'village' or a 'factory' operation the prospects for fractionation need discussion and debate. Further research is also required and a number of proposals are made in the chapters of this book.

Greater attention should be directed to improving the efficiency of green crop production and utilisation. Although it is technically possible by fractionation to produce leaf protein, We must not lose sight of the fact that some 80% of the harvested dry matter is best suited for ruminant consumption and certainly cannot be discarded. In many ways the use of fibrous green crops for human foods is exciting but there is a necessary balance between this and ruminant feeding.

Two centuries after the death of Hilaire Marin Rouelle, who published the first scientific papers on leaf protein, the world is certainly no less dependent on the politicians and the economic climates they create and foster. Progress has been made in green crop fractionation and the prospects are tantalising ecpecially if scientists in the wake of N. W. Pirie can help the necessary biochemical engineering to take place and develop reliable systems robust enough to be profitable compared with alternatives irrespective of the scale and objectives of the operation. Investigation of the future prospects of green crop fractionation deserves support and the book is a timely publication.

Gregory Rift Valley and early man

Geological Background to Fossil Man. Recent Research in the Gregory Rift Valley, East Africa. Edited by the late W. W. Bishop. (Scottish Academic Press: Edinburgh, 1978.) £25.

THE subtitle of this book is important, but it needs some explaining. The Gregory Rift Valley, for the benefit of non-geologists, is part of the great East African Rift—the system of valleys bounded by faults that extends southwards from the Red Sea for a distance of some 3,000 km. The section of this system known as the Gregory Rift, if one is to be precise, runs only for about 450 km from the bottom end of Lake Turkana in northern Kenya to the Lake Natron and Ngorongoro areas in northern Tanzania. But for the purposes of this book, the Gregory Rift has been interpreted more widely to include the northwards extension of the Rift—otherwise called the Ethiopian Rift—to the Afar in northern Ethiopia. The important early man sites at Hadar, and those in the Omo Valley and east of Lake Turkana thus come within the book's scope.

By geological accident, the Gregory Rift Valley—in both narrow and wide senses—is a field laboratory perhaps without equal for palaeontological and archaeological studies of early man as well as for investigating the structural, volcanic and geophysical aspects of rift systems. It was therefore a good idea of the late W. W. (Bill) Bishop's to organise in February 1975 a meeting at the Geological Society of London of many of the geologists and others who had worked or were still working in different parts of this great valley. This book—a collection of 35 papers—is the outcome. Not all the contributions are geological, but all in one way or another add to knowledge of the development of the Gregory Rift Valley and the environment of early man at different times in this part of East Africa.

A major part of the book is about the geology and palaeontology of the Baringo Basin. This was the area in which Bishop, and also Basil C. King—Director of the East African Geological Research Unit and Bishop's Professor for a period—devoted much of their own and their students' time between the mid-1960s and mid-1970s. It is a loss to science that with Bishop's tragically early death in 1977 and King's retirement from the chair of geology at Bedford Colege, London, systematic geological and palaeontological surveying in the Baringo area has almost ceased, although an archaeological project at Chesowanja does continue.

As events have turned out, the book has become a memorial tribute to Bishop's geological work in East Africa. It is therefore a pity that the volume is not all that it might have been. Bishop unfortunately died before he had completed the introduction to the three main parts and also the summing-up, so the book lacks these sections—though this is not the publisher's fault. I was, however, sorry to see so many typographical errors and minor editorial inconsistencies for which the publisher should take responsibility. These are understandable in the circumstances, but are to be regretted nonetheless. I should also mention that 'recent' in the subtitle means no later than 1975–76.

Geological Background to Fossil Man remains, however, a useful record of research in the Gregory Rift Valley and is especially valuable for the many geological maps and sections it contains. A special feature, and one that is rare these days, is the inclusion of a 1 : 10,000 coloured, foldout geological map of the area around Olorgesailie Prehistoric Site in Kenya. This map was prepared in 1946 by Robert M. Shackleton for the First Panafrican Congress of Prehistory in Nairobi but money was not available then for its publication. For this edition, grants towards the cost of publication have come from the Royal Society and the L. S. B. Leakey Foundation. The names of the stratigraphical units have been updated and the map was specially redrawn by Barbara Isaac. It accompanies a detailed account by Glynn Ll. Isaac of the geology of the Olorgesailie Formation. **Sarah Bunney**

Sarah Bunney was recently Editor at The International Louis Leakey Memorial Institute for African Prehistory in Nairobi, Kenya.

Ion-selective electrodes

Analysis with Ion-Selective Electrodes. By J. Vesely, D. Weiss and K. Stulik. Pp.243. (Wiley: New York, London and Sydney, 1978.) £16.

THE Ellis Horwood Series in Analytical Chemistry under the guidance of Dr R. A. Chalmers (Editor of Talanta) and Dr Mary Masson, of the University of Aberdeen, will be useful both to professional analysts, working in industry and the public services, and those few who teach analytical chemistry as a specialist subject in universities and polytechnics.

This volume is concerned with the applications of ion-selective electrodes as "sensors" that instrument technologists will need to interface with microprocessors—for example, when monitoring sodium and potassium levels for hospital patients. The authors are from Prague, home of J. Heyrosky and polarography fame, which guarantees that their work rests on a good theoretical background. The translation is smooth and clear, so that English readers can easily follow their text.

The work is divided into four chapters; the last is long and devoted to analytical applications. The first two deal with introductory theory and instrumentation, in some seventy pages with more than 300 references. Exact treatments are given of the theory of membrane potentials and activities, classification of electrode types with details of their selectivities and response characteristics, and information about measuring instruments used in potentiometry. The third chapter gives the experimental techniques used, including directions for the preparation and presentation of samples for analysis, descriptions of discrete and continuous measurements with explanations of calibration and standardisation techniques. This chapter finishes with an account of automated methods of analysis and the use of ion-selective electrodes in biochemistry, biology and medicine.

The final long chapter surveys the applications, as reported in the world's literature until about the end of 1977. It seems to be comprehensive; some 840 references are reviewed in 78 pages. These are dealt with rather in order of the reliability of present-day electrodes, starting with the applications for halogens and cyanide in greatest detail and continuing with sulphur compounds, nitrogen (including enzyme reactions), phosphorous and other nonmetals more briefly. Cation-selective electrodes are treated in the same way, starting with alkali and alkaline earth metals, followed by silver, mercury and so on. The book continues with tabulations for the determination of various inorganic materials and organic compounds and concludes with an Appendix of useful data tables.

This then is a valuable text and one does not need to criticise such honest work on the part of the authors. However, it is hoped that at a later time they may be encouraged to include the glass pH electrode, purposely avoided in this volume, as it is still the 'best' ion-selective electrode.

J. A. W. Dalziel

J. A. W. Dalziel is Reader in Analytical Chemistry at Chelsea College, University of London, UK.

announcements

Meetings

4–18 March, **Comparative Biology of the Nervous System,** Caracus (Dr Guillermo Whitfembury, Director of CLAB, Instituto Venezolano de Investigaciones Cientificas, Apartado 1827, Caracus, Venezuela).

9–10 March, **New York Einstein Centennial Celebration** (Einstein Committee, The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

12–16 March, **Labex International '79,** Birmingham (Industrial and Trade Fairs Ltd, Radcliffe House, Blenheim Court, Solihull, West Midlands, UK).

13–16 March, **Tunnelling '79,** London (Christopher Bradley Ltd, 78 Vineyard Hill Rd, Wimbledon Park, London SW1, UK).

15 March, **Charge Coupled Devices in Signal Processing,** London (Dr A. Holmes-Seidle, Fulmer Research Institute, Stoke Poges, Slough, UK).

27–29 March, **SEA-CON (79),** Brighton (C. G. Hague, Kent Instruments Ltd, 27B Bell St, Reigate, Surrey, UK).

28–30 March, **Process Engineering—the Future,** Loughborough (The Conference Secretariat, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

1 April, **More Physics, Less Relevance?,** Cambridge (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

3–5 April, **Annual Chemical Congress,** Bristol (Dr John F. Gibson, The Chemical Society, Burlington House, London W1, UK).

3–6 April, **3rd International Symposium on Distillation,** London (S. A. E. Buxton, The Institution of Chemical Engineers, 165-171 Railway Terrace, Rugby, UK).

9–11 April, **River Pollution Control,** Oxford (Conference Organiser, Water Research Centre, Medmenham Laboratory, Henley Rd, Medmenham, Bucks, UK).

9–11 April, **Enzyme Inhibitors as Drugs,** London (Mrs J. Kruger, Dept of Pharmacology, School of Pharmacy, University of London, 29-39 Brunswick Square, London WC1, UK).

9–11 April, **Pollution from Road Vehicles,** Warwick (NSCA, 136 North St, Brighton, Sussex, UK).

10–11 April, **Symposium on Straw Decay,** Hatfield (Dr E. Grossbard, Hatfield Polytechnic, Bayfordbury House, Lower Hatfield Rd, Hertford, UK).

16–21 April, **Freeze-etching in Electron Microscopy,** Woods Hole (Admissions Office, MBL, Woods Hole, Massachusetts 02543).

18–19 April, **Photochemistry, Lasers and Spectroscopy,** Newcastle upon Tyne (Dr John F. Gibson, The Chemical Society, Burlington House, London W1V0, BN, UK).

2–4 May, **Drug Treatment in Chronic Cerebrovascylar Disorders,** Milan (Dr G. de Gaetano, Istituto di Ricerche Farmacologiche "Maro Negri", 20157 Milano, Via Eritrae, 62 Italy).

8 May, **Efficient Use of Resources: Implications for the Agricultural Engineer,** Kenilworth (Mrs E. J. Holden, The Institution of Agricultural Engineers, West End Rd, Silsoe, Bedford, UK).

APPOINTMENTS VACANT

UNIVERSITY OF HONG KONG
DEPARTMENT OF ANATOMY
SENIOR LECTURESHIP IN ANATOMY
(Re-advertisement)

Following the establishment of a Dental School, applications are invited for appointment from September 1, 1979, to a post of Senior Lecturer in Anatomy.

Applicants should be either dental, medical or science graduates with experience in teaching anatomy to preclinical dental students. The appointment carries the responsibility for coordinating and implementing all anatomical teaching within the dental course. The appointee will be expected to engage in research work and may be required to teach other students on occasion. Facilities exist within the Department for a major research interest to be built up in one of the oral biology fields.

Annual salary (superannuable) is: HK$98,700 by 4,260 to 120,000 by 4,200 to 132,600 (£1=HK$9.40 approx.). Starting salary will depend on qualifications and experience.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

Closing date for applications is **March 15, 1979.** 9569(A)

Central Birmingham Health District
BIRMINGHAM MATERNITY HOSPITAL
Infant Development Unit
CYTOGENETICIST
(Principal Biochemist Grade)
(£6,999 to £9,177)

Applications are invited for this new ost of Principal Cytogeneticist. The aboratory offers a full range of cytoenetic investigation and has Regional s well as District commitments. The ppointee will be responsible to the Consultant Pathologist for the organiation of work within the laboratory, uality control and the introduction of ew techniques. Applicants should old a relevant science degree and be ully experienced in the field of Cytoenetics.

Visits to the laboratory may be rranged by appointment with Dr ameron, Tel. 021 454 4851 ext. 224 Children's Hospital).

Application forms and job description from Personnel Officer, Birmingam Maternity Hospital, Birmingham 15 2TG. Tel. 021 472 1377.

9511(A)

UNIVERSITY OF MALAWI
Bunda College of Agriculture

Applications are invited for the following posts in the

CROP PRODUCTION DEPARTMENT

tenable from September 1, 1979:

LECTURER IN BIOMETRY

Applicants should have a good first degree in Agriculture, Mathematics, or the natural sciences with postgraduate qualifications and experience in statistics as applied to agriculture. The appointee will be responsible for teaching agricultural statistics.

LECTURER IN HORTICULTURE

Applicants should have a good first degree in Agriculture or Horticulture with postgraduate qualifications in Horticulture. Practical research or production experience in Horticulture would be an advantage. Duties of the post include teaching the horticulture aspects of crop production and establishing a research programme in fruit or vegetable production.

LECTURER IN SOIL SCIENCE (Two Posts)

Applicants should have a good first degree in Agriculture or Soil Science with postgraduate qualifications and practical field experience in soil chemistry or soil physics. Duties of both posts include teaching the soil environmental aspects of crop production.

LECTURER IN AGRICULTURAL ENTOMOLOGY

Applicants should have a good degree in Agriculture, Biology or Zoology with postgraduate qualifications and experience in entomology as applied to agriculture. Duties of the post include teaching entomology as part of the crop protection element of crop production.

Salary Scale: K3,500 to K6,600 p.a. (£1 sterling=K1.62.) The British Government may supplement salaries in range £3,450 to £3,654 p.a. (sterling) for married appointee and £2,340 to £2,544 p.a. (sterling) for single appointee (reviewed annually and normally free from all tax) and provide children's education allowances and holiday visit passages. If no British Government supplementation is available, the University may pay an addition of between K1,320 to K1,656 p.a. (taxable in Malawi). Family passages, superannuation scheme; gratuity 15 to 25%; biennial overseas leave; housing and various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of Malawi, P.O. Box 278, Zomba, Malawi, by March 19, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9568(A)

MEDICAL RESEARCH COUNCIL
VIROLOGY UNIT
Institute of Virology
UNIVERSITY OF GLASGOW

A vacancy exists for a research scientist with experience in enzymology and/or protein biochemistry. The successful candidate would investigate the properties of certain Herpes Simplex Virus induced biologically active polypeptides (e.g. DNA polymerase, thymidine kinase), and be expected to pursue individual research problems as well as collaborative projects with other staff. Previous experitnce with animal virus systems is advantageous, but not essential.

The position is a three or five year limited-term appointment on the M.R.C. non-clinical scientific staff with salary starting at an appropriate point on the Grade II scale (£3,883 to £6,080). M.R.C. Pension Scheme. Applicants should send a curriculum vitae giving full details of qualifications and experience and the names of three Referees to:-

Professor J. H. Subak-Sharpe,
Institute of Virology,
University of Glasgow,
Church Street,
GLASGOW,
G11 5JR

by **February 28, 1979.** 9486(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF PATHOLOGY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from biological scientists with interests in virology, cell biology, or immunology. The successful applicant will join a team investigating lymphocyte-virus interactions during EB virus infection in vitro.

This grant-supported appointment will carry a salary on the scale beginning £3,833 per annum, depending on experience. (Scale under review.) The appointment will be for two years in the first instance, and is likely to be renewed thereafter for a further three years.

Replies in writing, giving the names and addresses of two referees to Professor M. A. Epstein, Department of Pathology, The Medical School, University Walk, Bristol BS8 1TD, by February 28, 1979. 9580(A)

Southampton THE UNIVERSITY
DEPARTMENT OF PHYSICS

Applications are invited for two **LECTURESHIPS** in the Department of Physics. The persons appointed will be expected to play a full part in the Department's programme of teaching and research in experimental physics. It is likely that preference will be given to candidates with research experience in the fields of condensed matter physics, low-temperature physics and space physics.

Salary scale £3,883 to £7,754 per annum plus U.S.S. The initial salary will depend on qualifications and experience.

Further particulars may be obtained from Mrs E. C. P. Sears, Staffing Section, The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than March 26, 1979. Please quote reference number 1703/A/Na. 9470(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
RESEARCH ASSISTANT IN BIOCHEMISTRY

urgently required to study the biological role of peptides released after activation of pancreatic zymogens. A knowledge of peptide chemistry and/or organ culture desirable but not essential. The appointment is in the Department of Surgery and will be for three years in the first instance with the possibility of registering for a Ph.D. degree.

Emoluments according to experience; minimum starting £3,834 p.a. inc. London weighting.

Please send curriculum vitae to Dr D. Grant, Department of Surgery, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. There is no closing date, suitable applicants will be interviewed immediately. 9593(A)

oxford polytechnic
DEPARTMENT OF BIOLOGY
TECHNICIAN IN HUMAN PHYSIOLOGY

(Salary £3,732 to £4,146)

Candidates should have degree, HNC, or equivalent qualification, and experience with electrophysiological equipment. Placement on salary scale according to age and experience.

Further details and application forms may be obtained from **the Deputy Administrator, Oxford Polytechnic, Oxford OX3 0BP.** 9563(A)

UNIVERSITY OF JOS
JOS NIGERIA

VACANCIES IN THE FACULTY OF MEDICAL SCIENCES

Applications are invited from suitably qualified candidates to fill the following vacancies in the Faculty of Medical Sciences of the University of Jos.

A. *POSTS*:

Professor/Reader/Senior Lecturer/Lecturer I and II in the following specialities: —

(1) Medicine
(2) Paediatrics
(3) Pharmacology and Therapeutics
(4) Psychiatry
(5) Surgery
(6) Obstetrics and Gynaecology
(7) Community Medicine
(8) Anaesthesia
(9) Microbiology
(10) Chemical Pathology
(11) Pathology
(12) Haematology and Blood Transfusion.

(i) *Professor/Reader*

Qualifications:

The Candidate, who should have a post-graduate qualification registerable with the Nigeria Medical Council, should be an authority in his field and should have several years' experience in his area of competence. He should have evidence of undoubted ability in research, such as contributions in reputable journals and should be capable of directing and supervising the research of junior colleagues. He should be capable of giving both administrative and academic leadership.

(ii) *Duties*:

The successful candidate would be involved with planning and organising undergraduate clinical programmes and in research. He would be expected to have the resourcefulness and energy required to meet the challenge of a new department.

B. *Senior Lecturer/Lecturer*:

(i) *Qualifications*:

Candidates for 1, 2,, 3 and 4 should possess an M.R.C.P. or similar post-graduate qualification.
Candidates for 5, should possess an F.R.C.S.
Candidates for 6, should possess an M.R.C.O.G.
Candidates for 7, should possess D.P.H./M.P.H. and possession of an M.R.C.P. or M.F.C.M. would be an advantage.
Candidates for 8, should possess an F.F.A.R.C.S. or D.A.
Candidates for 9, 10, 11 and 12 should possess an M.R.C. Path., a Ph.D. or equivalent qualification.

In the case of Senior Lecturers, candidates should possess not less than five years' experience in research and teaching in the speciality. Possession of a Ph.D. would be an advantage, as would training and experience in any sub-speciality in these fields.

(ii) *Duties*:

Successful candidates would be expected to be capable of interdisciplinary research and teaching, and would be responsible to the Head of Department for the organisation of clinical instruction.

C. *SALARY*:

Professor ...	... GL 16 — N11,268 x 576 — N12,420 per annum
Reader ...	... GL 14 — N 8,868 x 320 — N 9,828 per annum
Senior Lecturer	... GL 13 — N 7,764 x 320 — N 8,724 per annum
Lecturer I	... GL 11 — N 6,444 x 180 — N 6,984 per annum
Lecturer II	... GL 10 — N 5,460 x 162 — N 6,432 per annum

(N 1 equals approx. £0.80)

D. *CONDITIONS OF SERVICE*:

Successful candidates will be on probation for the first two years and afterwards confirmed to retiring age if their services are considered satisfactory. Other fringe benefits include pension scheme, car allowance, part furnished accommodation, or housing allowance in lieu of accommodation. 25 per cent Contract Addition is payable to all expatriates.

E. *METHOD OF APPLICATION*:

(a) Interested candidates in Nigeria are required to forward detailed applications (ten copies) to the Registrar, University of Jos, P.M.B. 2084, Jos, giving the following information: Post desired, full name, date and place of birth, nationality, permanent address, telephone number, if any, current postal address and telephone number, if applicable, marital status, number and ages of children, educational institutions attended with dates, full qualifications plus copies of certificates, previous employment with dates, present employment with dates and salary, list of publications, names and addresses of three distinguished scholars in relevant field as referees, two passport photographs of self. Candidates are advised to request their referees to forward references on them directly and under confidential cover to the Registrar to reach him not later than February 14, 1979.

(b) Overseas candidates should forward their applications (four copies) to the Principal Assistant Secretary (Recruitment), National Universities Commission, London Office, 180 Tottenham Court Road, London W1P 9LE, England, marked "Registrar/Jos" and giving the details listed in (a) above. Similarly, candidates should request their referees to forward references on them directly and under confidential cover to reach the London Office by February 14, 1979.

N.B. Further details are available from the London Office.

YSD/SA: REGISTRAR.

9574(A)

IMMUNOLOGIST/ VIROLOGIST

Two positions are available immediately at the Assistant Professor level for a Cellular Immunologist and a Virologist to work in the Bovine Leukemia Research Unit. Applicants should have a Ph.D. or D.V.M. degree with post-graduate training in the appropriate discipline.

Qualified applicants should send a résumé, copies of representative publications and the names of three people who may be contacted for references to:, Dr Jorge F. Ferrer, Chief, Section of Viral Oncology, University of Pennsylvania School of Veterinary Medicine, New Bolton Center, R.D. 1, Kennett Square, Pa. 19348. 9298(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
RESEARCH ASSISTANT IN CELL BIOLOGY

required to join a Cancer Research Campaign funded 3-year project investigating human pancreatic and other common cancers. Experience in cellular assays and tissue culture desirable but not essential.

Emoluments £3,834 to £4,333 (under review). The successful candidate will be expected to obtain a Ph.D. degree.

Applications and further particulars from the Establishment Officer, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 9586(A)

CHILDREN'S HOSPITAL BIRMINGHAM
TECHNICIAN OR BIOLOGICAL SCIENCE GRADUATE

required for a research post. The successful applicant will be concerned with a leukaemia and non-Hodgkins Lymphoma study. Previous experience in immunology helpful but not essential. Appointment for one year in the first instance.

Salary according to experience and qualifications.

For further details and an application form please contact Dr F. G. H. Hill, Consultant Haematologist, Haematology Department, The Children's Hospital, Ladywood Middleway, Birmingham B16 8ET. Telephone: 021-454 4851. Closing date: March 15, 1979. 9590(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF GEOLOGICAL SCIENCES
LECTURER IN HYDROGEOLOGY

Applications are invited for the above post, the duties of which will principally include the teaching of Hydrogeology at M.Sc. Course level and the supervision of Course project work. The successful applicant will be expected to pursue research in the field of hydrogeology.

Applicants should have a good honours degree. A postgraduate qualification in Hydrogeology and practical experience would be advantageous.

Salary, according to age and experience, in the range £3,883 to £7,754 (to be reviewed) plus superannuation.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (3 copies) including curriculum vitae and naming three referees should be sent by March 2, 1979.

Please quote: Ref NG3. 9589(A)

UNIVERSITY OF LIVERPOOL
SCHOOL OF DENTAL SURGERY
TECHNICIAN

to work in electron microscope unit Research interests are concerned principally with mineralised tissues The unit is shortly to be equipped with a Jeol Temscan system with Link energy dispersive analytical equipment Previous experience in electron microscopy an advantage but training could be given to suitable applicant with previous relevant laboratory experience ONC or equivalent as minimum qualification.

Salary on scale up to £3,060 p.a. (under review) according to qualifications and experience.

Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX.

Quote Ref: RV/481/N. 9579(A)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF LINGUISTICS
RESEARCH ASSOCIATE

for S.S.R.C. Project on the Intelligibility of Speech to Children, for two years from March, 1979.

Qualification in psycholinguistics and/or linguistics plus some familiarity with experimental method required.

Salary: £3,883 to £4,382 per annum.

Applications with curriculum vitae and names of two referees to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, by February 16, 1979.

Please quote: Reference 5004.

9577(A)

UNIVERSITY OF LEICESTER
PHYSICS RESEARCH Ph.D.

The Department of Physics offers excellent research opportunities leading to the degree of Doctor of Philosophy in the following areas:

IONOSPHERIC PHYSICS
NUCLEAR ELECTRONICS
QUANTUM MOLECULAR PHYSICS
SOFT X-RAY SPECTROSCOPY
SOLID STATE PHYSICS
THEORETICAL PHYSICS
X-RAY ASTRONOMY

Further details and application forms may be obtained from Professor J.L. Beeby, Department of Physics, University of Leicester, Leicester LE1 7RH. 9488(A)

UNIVERSITY OF EDINBURGH
THE EDINBURGH SCHOOL OF AGRICULTURE
LECTURER IN ANIMAL PRODUCTION

Applications are invited from suitably qualified graduates for a post of LECTURER IN ANIMAL PRODUCTION. The successful candidate will be involved in courses for postgraduate, undergraduate and HND students and will be encouraged to develop research interests.

Salary on scale £3,883 to £7,754 per annum.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications should be lodged not later than March 9, 1979.

Please quote: Reference 1014.

9578(A)

CAREERS in SCIENTIFIC COMPUTING and ELECTRONIC ENGINEERING

CHALLENGING OPPORTUNITIES TO WORK ON:

- **MICROPROCESSORS**
- **REAL-TIME PROGRAMMING**
- **NETWORKS**
- **LOGIC DESIGN**
- **INSTRUMENTATION**
- **ACCELERATOR CONTROL SYSTEMS**

Daresbury Laboratory is developing major national facilities in the fields of computer networking, atomic, molecular and biological sciences and nuclear physics. The exploitation of these facilities requires first-class computing support. Computers at the laboratory include an IBM 370/165, GEC 4070s, PDP-11s and Interdatas.

• COMPUTER NETWORKS:
Development and support of communications software for interactive terminal, graphics and remote job entry access to the SRC's computing centres using microprocessor based communications hardware and mini-computer pocket switches and front end processors.

• LOGIC DESIGN:
Interface design for mini-computers using the latest microprocessor techniques, also communications interfacing for remote data processing. Specialised design of data acquisition systems.

• DATA ACQUISITION:
Programmers are required for the development of data acquisition systems using LSI and PDP-11 computers connected to an IBM 370/165. There are opportunities to work with large and small systems in a stimulating scientific environment. Relevant programming experience would be an advantage but is not essential.

• INSTRUMENTATION:
Design and development of specialised analogue and digital instrumentation for processing electrical signals from a wide range of charged particle and photon detectors. The most up-to-date facilities for R&D are available.

• ACCELERATOR CONTROL SYSTEMS:
Development of an on-line process control system for the Daresbury Synchrotron Radiation Source (a 2 GeV Electron Storage Ring), using Interdata computers. Experience in programming in both high level and assembler languages, and also in digital interface hardware, would be an advantage.

Applicants should have a good honours degree in a relevant scientific discipline. Appointments will be made depending on qualifications and experience at SO level.

Scientific Officer - £2,839-£4,415 (Salaries are currently under review)

Closing date: 15th March, 1979.

Please write or telephone: Warrington 65000, Ext. 467, for an application form quoting reference No. DL/65

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

Energy..Energy.. Energy...

The potential of both conventional and unconventional energy technologies in helping meet future energy needs is a topical and important subject.

If the full potential of these technologies is to be realised, research, development and demonstration programmes all have a vital part to play.

The Energy Technology Support Units of the U.K.A.E.A., located at Harwell, is responsible on behalf of the Department of Energy for initiating and managing many of these programmes, all of which are now expanding.

SCIENCE OR ENGINEERING GRADUATES in their late twenties or early thirties, are needed in the following areas:-

-Planning the national programmes.
-Promotion and development of new and existing technologies in all areas of energy use to establish greater efficiency.
-Continuing development of solar, wind, wave, geothermal and tidal programmes.

Especially welcome are applications from those with industrial experience or those able to discuss technological matters effectively with senior people in both industry and Government.

Salary range: £5,514-£7,380

Write or 'phone: Steve Beackon, Personnel Department, UKAEA, Harwell, OXON, OX11 0RA. Abingdon (0235) 24141. Ext. 2058. 9507(A)

HARWELL

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN PURE MATHEMATICS

Applications are invited for the above post in School of Mathematics, Trinity College, Dublin, which will become vacant on October 1, 1979.

Salary scale: £4,232 to £8,321 p.a. Appointment is likely to be made within the range £4,232 to £4,680.

Application forms and further particulars relating to this post may be obtained from:

The Establishment Officer,
West Theatre,
Trinity College,
Dublin 2,

The closing date for receipt of applications will be **March 1, 1979.** 9487(A)

UNIVERSITY OF READING LECTURERSHIP IN PHYSIOLOGY AND BIOCHEMISTRY

Applications are invited for a Lectureship in Physiology. Candidates should have a degree in Physiology or related subjects, with interests in cardiovascular, respiratory, renal or muscle physiology and biochemistry and evidence of active research.

The appointment will be in the Lecturer salary scale but, other things being equal, within the range £3,883 to £5,842 per annum.

The person appointed should take up duties on June 1, 1979 or as soon as possible thereafter.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than March 10, 1979. 9534(A)

UNIVERSITY OF GLASGOW LECTURESHIP IN MATHEMATICS

Applications are invited for a Lectureship in the Department of Mathematics, duties to commence on October 1, 1979. Salary will be within the range £3,975 to £5,830 of the Lecturers' scale £3,975 to £8,250 according to qualifications and experience (which may be in any branch of Pure or Applied Mathematics).

Further particulars may be obtained from the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (8 copies), giving the names and addresses of three referees, should be lodged on or before March 31, 1979.

In reply please quote Ref. No. 4362M. 9556(A)

ST. HELIER HOSPITAL
Carshalton, Surrey

POSTDOCTORAL RESEARCH ASSISTANT

required to work in Dermatology Department using immunological and biochemical techniques to study various aspects of skin disease including Cancer.

Salary according to experience.

Application, with full details of experience and names and addresses of three referees to Dr E. Rhodes, Dermatology Department at above address, from whom further details can be obtained. 9564(A)

UNIVERSITY OF KENT AT CANTERBURY
Appointments in Electronics

Applications are invited for the posts of

LECTURER AND TUTORIAL FELLOW
in Electronics

Preference will be given to applicants with experience in one or more of the following fields: digital communications, microwaves, medical electronics, electromagnetism, fundamental physical electronics.

Salary scales: Lecturer £3,883 to £7,754; Tutorial Fellow £3,883 to £6,555.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH, to whom completed applications should be returned by March 12, 1979. Please quote: Ref. A4/79. 9565(A)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF OCCUPATIONAL HEALTH AND HYGIENE

RESEARCH OFFICER

Applications are invited from Honours graduates, preferably with Ph.D., for a post as Research Officer in Applied Physiology which has been established in the Department of Occupational Health and Hygiene. The person appointed will be required to assist and collaborate in studies of human respiratory and exercise physiology including physiological anthropometry, control mechanisms, sports physiology and the effects of occupational dusts and vapours. Applications from holders of HNC in physiology, medical physics or applied biology with relevant experience will also be considered.

Salary according to age, qualifications and experience on either the Range 1B salary scale £3,384 to £4,882 per annum or the Range 1A salary scale £3,883 to £6,555 per annum. The post is available for up to three years. Membership of the appropriate University superannuation scheme will be required.

Applications (three copies) together with the names and addresses of three referees should be sent to The Senior Administrative Assistant, The Medical School, University of Newcastle upon Tyne NE1 7RU, not later than March 12, 1979. 9566(A)

The Physiological Institute, Lehrstuhl 2, University of Goettingen, is offering a contract for the position of **COMPUTER PROGRAMMER** for its PDP-11 computer network. A knowledge of digital electronics would be advantageous. Application with curriculum vitae to: H. Schultens/EDV, Humboldtallee 7, D-3400 Goettingen, FRG. 9575(A)

SENIOR HISTOPATHOLOGIST

[HE ST GEORGE HOSPITAL

with conjoint appointment as Clinical Professor or Clinical Associate Professor

School of Pathology

University of New South Wales

Australia

Suitably qualified medical pracitioners are invited to apply for ppointment as Senior Histopathologist t this 550 bed teaching hospital of the Jniversity of New South Wales. The ppointee may also be offered the title f Clinical Professor (conjoint appointnent) or Clinical Associate Professor conjoint appointment) and as such vould be responsible to the University f New South Wales for teaching in he School of Pathology, with access o the facilities of that school.

The Histopathology Division provides comprehensive service to the Hospital nd is staffed with a second full-time pecialist and two Registrars. A fullime Senior Lecturer in Pathology is lso on site.

Salary is at the Senior Staff Specialist rate, currently $A39,364 p.a. Other onditions in terms of the Medical Officers' Hospital Specialists' (State) Award include study leave of three nonths for each five years' service nd limited right of private practice n terms of the procedures laid down y the Health Commission of New South Wales.

Written applications, including the iames and addresses of three referees lose with the Chief Executive Officer, The St George Hospital, Kogarah, 2217, on April 12, 1979. Enquiries concerning hospital duties should be directed to the Medical Superintendent, The St George Hospial, phone (02) 588 1111, and on Uiversity matters to Professor A. Lykke (02) 662 2770.

9537(A)

UNIVERSITY OF HONG KONG

Closing date for applications is **March 15, 1979.** 9570(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of

LECTURER IN ANIMAL BEHAVIOUR

tenable from October 1, 1979. Candidates should have field experience and be able to assist with ecological teaching and with the development of Joint Honours courses with Psychology and Anthropology.

Salary on the scale £3,883 to £7,754 per annum (under review) plus U.S.S. Applications (3 copies) naming three referees, should be sent by February 23, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

9463(A)

Radioimmunoassay Development

Our Radioimmunoassay kits are well established in the Haematology, Obstetrics/Gynaecology and Thyroid fields and make a substantial contribution to the company's 20% p.a. growth rate and current group turnover of more than £33m.

The group responsible for their development is expanding to meet the need for new products and we now have opportunities for experienced and skilled Radioimmunoassay Scientists to play a key role in our future development programme. Candidates must have appropriate experience in a commercial or specialist research environment and good academic training to degree level with a period in further research in Chemistry, Biochemistry or related subjects. Ability and success in developing Radioimmunoassay or related analytical methods should have been a strong feature in the career of the successful candidate. 1979 graduates (first or second degree) are unlikely to have sufficient experience.

The company is based in rural Buckinghamshire and this post offers considerable scope for scientists keen to join a successful and rapidly-expanding high technology organisation. Salaries will be in the range £5,600 – £7,600 depending on the qualities and experience of candidates. Conditions of employment are excellent and assistance with relocation will be given where needed.

In the first instance, please write with full details of career to: Dr. J. S. Allinson.

UNIVERSITY OF MANITOBA

DIVISION OF GENETICS, FACULTY OF MEDICINE AND HEALTH SCIENCES CENTRE

ASSOCIATE *or* ASSISTANT PROFESSORS

in areas of :

1. Clinical Genetics—M.D., F.R.C.P. or equivalent in Pediatrics. At least 3-4 years experience in Clinical Genetics/Genetic Counselling and Research to head Section of Clinical Genetics, Health Sciences Centre.
2. Basic Genetics—Ph.D. or M.D. with Research interests in the area of Somatic Cell Genetics, Population Genetics or Immunogenetics. Some experience in Graduate and Undergraduate teaching required.

Both appointments to commence on or after July 1, 1979. Send C.V. and references as soon as possible to Dr John L. Hamerton, Division of Genetics, Health Sciences Centre, 700 William Avenue, Winnipeg, Manitoba, R3E 0Z3. 9559(A)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOLOGY

Applications are invited for the post of Lecturer in the Department of Biology. Candidates should have a special interest in Plant Ecology and should expect to contribute fully to the general teaching in the Department.

Salary scale £3,883 to £7,754 per annum plus U.S.S. Initial salary will depend on qualifications and experience.

Further particulars may be obtained from Mrs E. C. P. Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH, to whom applications (seven copies), naming three referees should be sent, as soon as possible and not later than March 9, 1979. Please quote reference number 1609/R/Na. 9362(A)

UNIVERSITY OF LONDON ROYAL POSTGRADUATE MEDICAL SCHOOL

SAFETY OFFICER

Applications are invited for this newly established post, the holder of which will be Secretary of the Safety Committee and will be responsible to the School Secretary for the implementation of safety policy.

Applicants should have a sound knowledge of safety matters. Particular knowledge of safety considerations in laboratories would be an advantage, but is not essential.

Salary on grade II for academic-related Administrative Staff: £6,317 to £7,754 (under review) plus £450 a year London Allowance.

Superannuation under Universities Superannuation Scheme.

Further particulars should be obtained from the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS (tel: 01-743 2030, ext 352), to whom applications (6 copies) should be sent, naming three professional referees, to arrive not later than Wednesday, February 28, 1979. 9594(A)

GRADUATE or POSTDOCTORAL RESEARCH ASSISTANT required for 1¼ years in the Department of Microbiology for an M.R.C. research project on cytomegalovirus immunovirology. Laboratory experience in virology essential. Applications, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. M.C.2. 9553(A)

POSTDOCTORAL RESEARCH POSITION immediately available for a young Ph.D. in Biochemistry interested in working on Interferon. The project includes specific aspects of the molecular biology of induction and mechanism of action of Interferon. Experience in nucleic acid research including hybridisation and cell-free translation would be helpful. Applicants should send their curriculum vitae, bibliography and the name and address of two referees to: Dr Jean CONTENT, Institut Pasteur du Brabant, 28 ru de Remorqueur, B 1040-BRUSSELS, BELGIUM. 9558(A)

Ph.D. PHYSIOLOGIST

with special interest in reproductive physiology wanted to direct gynecologic endocrine laboratory at Tufts New England Medical Center Hospital. Send curriculum vitae to: Martin Farber, M.D., Associate Professor—Department of Obstetrics and Gynecology, Director—Division of Reproductive Endocrinology, Tufts New England Medical Center Hospital, 37 Benner St, Boston, Mass. 02111.

An Equal Opportunity Employer M/F. 9500(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

Applications are invited for the post of LECTURER IN MATHEMATICS. Applicants should have research experience and publications in Pure Mathematics, preferably in an area of TOPOLOGY.

The appointment, to commence on October 1, 1979, will be to the Universities' Lecturer scale:—£3,883 to £7,754 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: February 28, 1979. 9412(A)

SWINBURNE COLLEGE OF TECHNOLOGY

Hawthorn, Victoria, Australia

Applications are invited for appointment as

DEAN

FACULTY OF APPLIED SCIENCE

The appointment will be made either by contract, for at least three years, or on a permanent basis. If necessary, appropriate repatriation arrangements will be made for a contract appointment.

Swinburne is a tertiary institution currently affiliated with the Victoria Institute of Colleges, and with a large measure of autonomy. The Faculty of Applied Science offers courses at undergraduate and postgraduate levels in fields of Applied Chemistry, Biochemistry, Biophysics, Computer Science, Instrumental Science, Mathematics and Environmental Health. It has an academic staff of about 60 and approximately 550 cooperative (sandwich) full-time and part-time students.

Qualifications: Candidates should hold formal qualifications, preferably at postgraduate level, in a field of science appropriate to the activities of the Faculty. In addition, they should have had considerable experience in professional, industrial or research activities and in tertiary education at a senior level.

Salary: $A33,059 (current exchange rate $A1=£0.57 Stg. approximately).

Duties: The successful applicant will exercise responsibility for academic leadership and administrative coordination in the Faculty of Applied Science. The Dean is expected to liaise with outside industrial and professional groups.

Further information about the position, conditions of employment and application procedure may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date: **April 6, 1979.** 9571(A)

HAMBURG UNIVERSITY

West Germany

TECHNICIAN

required to join a team involved i polynucleotide chemistry and bio chemistry. The post is particularl suitable for a person who would no like to do routine work but to tak part in an interesting and intensiv research programme. Experience wit nucleic acid chemistry (oligonucleotide synthesis) is desirable.

Salary: DM 25.000 per annum.

Personal details and details of qualifications, experiences and curriculun vitae should be addressed to Professo Dr H. Köster, Universität Hamburg 2 Hamburg 13, Martin-Luther-King Plaz 6 (Institut für Organische Chemi and Biochemie). 9573(A)

MEDICAL RESEARCH COUNCIL
Laboratory Animals Centre

NUTRITIONIST

Scientists with postdoctoral research cperience in the nutrition of labora- ry animals, farm livestock or poultry e invited to apply for the post of ead of the Centre's Nutrition Depart- ent The successful applicant will be e focus of all aspects of the entre's work in this field and will ndertake research into the nutritional quirements of laboratory animals ading to general improvements in utrition with particular emphasis on reeding performance and the lowering f mortality rates He or she will also rovide a comprehensive advisory rvice to diet manufacturers and users f laboratory animals

Excellent conditions of service, tracting a salary commensurate with e, qualifications and relevant experi- ice.

Applications, enclosing a full urriculum vitae, should reach the irector, Laboratory Animals Centre, ledical Research Council Laboratories, 'oodmansterne Road, Carshalton, urrey SM5 4EF by March 1, 1979

9501(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of RESEARCH FELLOW in the above Department from biochemists or chemists with an interest in metalloproteins to work on a project, supported by the Science Research Council, on the equilibria and kinetics of oxygen binding by respiratory proteins and their subunits in collaboration with Dr E J Wood Candidates should possess a Ph D degree. The appointment will be made for a fixed period of up to three years

Starting salary in the range £3,883 to £4,382 on the 1A scale for Research and Analogous Staff (£3,883 to £6,555) under review) according to age, qualifications and experience.

Informal enquiries may be addressed in the first instance to Dr E J. Wood (telephone. (0532) 31751, Extn 66)

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/18/D Closing date for applications: February 26, 1979.

9476(A)

AGRICULTURAL RESEARCH COUNCIL

POULTRY RESEARCH CENTRE
King's Buildings, West Mains Road
Edinburgh EH9 3JS, Scotland

HIGHER SCIENTIFIC OFFICER

Applications are invited for the post within the H S O grade, Band II in the Reproductive Physiology Department at the above Centre.

Initially the successful candidate will be required to participate in the development and use of in vivo and in vitro systems to study lipogenesis, lipoprotein metabolism and related metabolic processes in relation to the production and control of egg-yolk constituents by the liver of the domestic fowl.

Previous experience in the use of enzymatic assay techniques, determination of intermediary metabites and methods of protein analysis is desirable

Qualifications Degree, H N.D./H N C or equivalent in Biochemistry/Chemistry with at least 5 years relevant post qualifying experience. Knowledge of related disciplines, e.g. physiology, endocrinology would be an advantage

Salary. In scale £4,101 to £5,448 22 days annual leave plus 10½ days public/privilege holidays A non-contributory pension scheme is in operation

Application forms may be obtained from the Assistant Secretary at the above address These should be returned to her not later than February 28, 1979 Please quote Reference No. PRC 795. 9557(A)

CENTRAL ELECTRICITY RESEARCH LABORATORIES

Kelvin Avenue, Leatherhead, Surrey, KT22 7SE

RESEARCH OFFICER

ENVIRONMENTAL PHYSICS SECTION

The Environmental Physics Section, whose role at CERL is to study the physical, meteorological, and mathematical aspects of the dispersion and fate of atmospheric emissions from power stations, requires a graduate/postgraduate physicist to undertake research on certain aspects of the global CO_2 problem These relate to the takeup of CO_2 at natural surfaces such as vegetation, forests, and the sea, as part of a programme to study the ground level deposition of airborne species like SO_2, NO_x, CO_2, and particulates. Accurate methods for measuring the flux of these species to ground need to be developed to study the CO_2 balance, the effects of air pollution on crops, and the transport of pollution over continental distances

The successful candidate would be expected to develop the necessary techniques, apply them in field experiments, and establish an informed position on the overall CO_2 problem. He/she would be working with other scientists concerned with the dispersion of emissions from power stations whose facilities include the latest mobile remote sensors, ground samplers, meteorological instrumentation, and data processing

Candidates should have a good honours degree in physics, preferably with post-graduate experience in a relevant field such as environmental science or meteorology

The Laboratories are situated in a pleasant part of Surrey and offer attractive conditions of service, and facilities for the total of 800 Research and Support staff engaged in a broad spectrum of research into the materials, technologies and plant performance problems of the Central Electricity Generating Board

This appointment will be made within incremental salary ranges rising to £6035 or £7050 plus a Self-Financing Productivity Scheme payment ranging between £8 and £17 per month

Application forms are obtainable from the Head of Personnel Development & Services, Central Electricity Research Laboratories, at the above address or telephone Leatherhead 74488 Ext 363, quoting reference number RL/5. Closing date is **Friday 23 February 1979.** 9587(A)

CHAIRPERSON

Applications are sought for the position of chairperson of the Department of Veterinary Physiology and Pharmacology, Iowa State University Available July 1, 1979 Qualifications include the DVM and/or Ph D degrees, academic leadership potential, and demonstrated excellence in teaching and research

Send applications, including curriculum vitae and bibliography by April 1, 1979, to Dr F Ahrens, Department of Veterinary Physiology and Pharmacology, Iowa State University, Ames, Iowa 50011

An Affirmative Action/Equal Opportunity Employer 9543(A)

YARMOUK UNIVERSITY

Irbed—Jordan

invites applications for teaching positions for the academic year 1979-1980 in the following areas

Biological Sciences Embryology-Comparative Anatomy, Animal Physiology, Microbiology, Plant Pathology, Taxonomy-Ecology, Plant Physiology

Appointments will be at the level of Assistant Professor, Associate Professor or Professor Applicants must hold a Ph.D. Placement will be according to experience in teaching and research Salaries range· $16,000 to $27,500 (9 months). Fringe benefits include travel expenses at beginning and termination of employment and for home leave every three years for appointee and members of family, health and life insurance, and furnished accommodation at reasonable cost. 9523(A)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL BIOENGINEERING

Applications are invited for a newly-established post of LECTURER IN BIOENGINEERING in the Department of Surgery The Lecturer will work in close collaboration with the N H S Department of Medical Physics, Queen's Medical Centre, Nottingham

The successful candidate will be expected to have special experience in bioengineering and computer analysis, and will help to extend collaboration between departments in the Medical School and the Department of Medical Physics

Salary will be within the non-clinical scale for lecturers with membership of U S S/F S S U. as appropriate. The successful applicant will be expected to take up the appointment as soon as possible

Those interested in this post are invited to write for details and a form of application to the Deputy Registrar, Medical School, Queen's Medical Centre, Nottingham NG7 2UH to whom completed applications should be returned by March 1, 1979

9469(A)

POSTDOCTORAL POSITION available for a 2-3 year study of the role of prostaglandins and cyclic nucleotides in stimulus-secretion coupling Curriculum vitae and two letters of recommendation should be sent to: Dr R. P Rubin, Department of Pharmacology, Medical College of Virginia, Richmond, Virginia 23298, U S A

RESEARCH CHEMIST

PHARMACEUTICAL INDUSTRY

Pfizer Central Research is part of a leading international group engaged in the research, development, manufacture and marketing of a wide range of human medicinal and animal health products.

We have a vacancy for a chemist to work in our Agricultural Chemistry Department. Preferred male or female applicants will have:–

- Qualifications at HNC, GRIC, or B.Sc. level.
- Several years experience in synthetic organic chemistry, preferably in the pharmaceutical industry.
- Proven ability as an experimentalist.
- The ability to work with minimal supervision.

In return we offer:–

- A competitive starting salary within an incremental pay system.
- Varied synthetic work supported by first class analytical and library facilities.
- Modern laboratories within easy reach of pleasant seaside resorts, the Kentish countryside and Continental Europe.
- Flexible working hours.
- Participation in Bonus, Salary Continuance, Pension and Death Benefit schemes.
- A flourishing sports and social club.

Pfizer

If you are interested in this opportunity write or telephone for an application form to:– **Graham Marshall, Personnel Officer, Pfizer Central Research, Sandwich, Kent. Tel: (03046) 3511**

9561(A)

LOTHIAN HEALTH BOARD

BASIC GRADE CYTOGENETICIST

Applications are invited from science graduates for the above post based at the Department of Pathology, Royal Hospital for Sick Children, Edinburgh. Experience in human cytogenetics desirable.

All types of cytogenetic investigation are undertaken including the prenatal diagnosis of chromosome disorders, blood culture analysis, bone marrow investigation and the karyotyping of postmortem and spontaneous abortion material. A broad training in cytogenetics would be afforded.

Arrangements to visit the department may be made by telephoning 031-667 1991, ext. 270.

Salary scale: £2,991 per annum to £4,899 per annum with placement according to qualifications and experience.

Applications, which should be typewritten, giving particulars of age, qualifications and previous experience, together with the names and addresses of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ by February 22, 1979.

9498(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF INORGANIC AND STRUCTURAL CHEMISTRY

Applications are invited for a post of

POSTDOCTORAL RESEARCH FELLOW

from inorganic or physical chemists. Candidates should already possess, or expect to receive within the next few months a Ph.D. degree. Experience in inorganic synthesis or pulse nmr would be valuable. The appointee will take part in a project, supported by S.R.C., and will prepare and study NEW SOLID STATE INORGANIC PROTON CONDUCTORS applicable to fuel or electrolysis cells, hydride batteries or electrochromic displays. The appointment will be for a fixed period of two years to commence as soon as possible or from October 1, 1979.

Starting salary in the range £3,883 to £4,382 on the 1A scale for Research and Analogous Staff (£3,883 to £6,555) (under review) according to age, qualifications and experience.

Informal enquiries may be addressed in the first instance to Dr A. T. Howe, Department of Inorganic and Structural Chemistry (Tel: 0532-31751, ext. 6061).

Applications (quoting reference number 44/5) should be made as soon as possible to the Registrar, The University, Leeds LS2 9JT (from whom further particulars may be obtained). 9581(A)

ZOOLOGY CHAIRMAN GUELPH

The College of Biological Science is searching for a Chairman. The department wishes to recruit a scholar with expertise in one of the areas of specialization of the department.

The department has a large undergraduate teaching component both as a service function as well as in its own disciplinary area. At the graduate level the department specializes in:— aquatic science, marine biology, parasitology, environmental physiology, fish and wildlife biology, management and behaviour.

Salary and rank are commensurate with experience.

Recommendations and applications should be sent to. Secretary, Selection Committee, c/o Professor K. Ronald, Dean, College of Biological Science, University of Guelph, Guelph, Ontario, N1G 2WI.

Position subject to final budgetary approval.

9526(A)

(Re-advertisement)

RESEARCH SCIENTIST

THE PHARMACOLOGY OF FEVER

The National Institute for Biological Standards and Control is a recently established multi-disciplinary Institute concerned with the standardisation and control of biological substances important in medicine

The Institute's Division of Hormones requires a research scientist for a three year appointment for work involving the mechanism of fever production, the action of bacterial pyrogens and the development of methods for the measurement of their effects The work will provide good opportunities for collaboration both in the UK and internationally.

Candidates should preferably possess a PhD although those with a good honours degree in pharmacology or a related subject will be considered. It is hoped that the person appointed will be able to take up the post as soon as possible

Salary will be in accordance with the scales for university non-clinical lecturing staff and will initially be in the range **£4,300 to £6,500 p.a**

Please write or telephone, for an application form quoting Ref. No. 0138, to the Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, Hampstead, London NW3 6RB Tel: 01-435 2232, ext. 211. Closing date: 23.2.79.

LECTURER IN CROP PHYSIOLOGY

Applications are invited for the position of Lecturer in the Department of Plant Science. Applicants should have qualifications and research experience in crop physiology, preferably combining a sound knowledge of physiological principles with personal experience of crop or pasture production Teaching at undergraduate and postgraduate levels will necessitate competence in such topics as photosynthesis, water relations, competition etc

Commencing salary according to qualifications and experience Present salary scale is: NZ$11,529 to $14,250. Travel and removal expenses are reimbursed up to specified limits New Zealand Government Superannuation is available

Initial enquiries may be made to the following now on study leave in England. Dr P. Jarvis, Plant Physiology Department, University of Sussex, or Dr W R Scott, Plant Breeding Institute, Cambridge.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College

Applications close on **April 16, 1979.**

9541(A)

UNIVERSITY OF OXFORD

RESEARCH OFFICERSHIPS IN NUCLEAR AND PARTICLE PHYSICS

The University proposes to appoint three Research Officers in the Department of Nuclear Physics for a period of three years, from October 1, 1979 or earlier if possible. Salary according to age on the University Lecturer scale (under review) £3,883 to £8,257 One post will be filled in experimental high energy physics and two in experimental structure physics. Further particulars may be obtained from the department

Applications (one typed copy) including a statement of qualifications, publications and the names of two referees, should reach Professor K W Allen, Department of Nuclear Physics, Keble Road, Oxford OX1 3RH by March 15, 1979 (Revised)

9518(A)

City of Glasgow District Council

MUSEUMS AND ART GALLERIES

Conservation Officer (Scientific)

Salary Scale: £3,279 to £4,773*

Applications are invited for a vacancy in a conservation science laboratory. Candidates should possess a good honours degree in physics, chemistry, metallurgy, materials science or a related subject. Museum or research experience would be advantageous.

The successful candidate will work closely with a large conservation staff and will be expected to develop methods of conservation treatment and apply scientific techniques into research into museum objects.

*Including Supplement

Superannuation, Sick Pay and Staff Life Assurance Schemes in operation. Removal expenses, legal fees and lodging and subsistence allowances payable in appropriate cases.

Appointment subject to medical fitness. Local authority salary and conditions apply.

Further details and an application form may be obtained from The Director, Art Gallery and Museum, Kelvingrove, Glasgow G3 8AG (Tel: 041-334 1134). Completed application forms to be returned by Friday, February 23, 1979.

PLEASE QUOTE REF. NA/6/79.

9489(A)

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)

Chair of Pharmacology and Materia Medica

Applications are invited from suitably-qualified candidates in any branch of the sciences of pharmacology, including clinical pharmacology, for the above Chair in the University of Wales at the Welsh National School of Medicine, Heath Park, Cardiff. This post will become vacant following the retirement of Professor J.D P Graham and it is hoped that the successful candidate will be able to take up the appointment on October 1st 1979 or as soon as possible thereafter

The salary will be either within the scale for clinically-qualified Professors—currently up to a maximum of £12,C84 or that for non-clinical Professors (currently up to a maximum of £11,055) with participation in the Universities Superannuation Scheme

Further particulars for the post may be obtained from the **Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN** to whom applications should be submitted by 16th March, 1979.

9490(A)

If you are a graduate, age 26 or over, with a first or second class honours degree plus at least four years' relevant postgraduate experience and would like to make a career in research administration, a post of

Scientific Administrative Officer

in the Medical Research Council headquarters office in London should be of interest to you. Research experience in fields associated with medicine in the broadest sense and a research degree would be an advantage. Initially the successful candidate is likely to work in the Grants and Training Awards Section which is responsible for handling all aspects of the project grants, fellowships and studentships awarded by the Council.

The MRC is the main UK Government agency for the promotion of medical research and its headquarters office is responsible for the administration of an extensive programme of research which is carried out by directly supported staff in the Council's own establishments as well as by other research workers funded by MRC grants and other awards.

Salary will be in the range £5,619 to £7,363 per annum. In addition there is a pay supplement to compensate for contributions to the Council's pension scheme. Subject to satisfactory completion of a two years' probationary period, the appointment will be established; there is opportunity for promotion.

Application forms may be obtained by writing to or telephoning Miss M. Gale, Medical Research Council, 20 Park Crescent, London W1N 4AL (Tel. No. 636 5422 Ext. 35). Closing date for applications 26 February, 1979. Please quote P. 1002/39.

9529(A)

MRC
Medical Research Council

THE UNIVERSITY OF LEEDS
DEPARTMENT OF MEDICAL PHYSICS

Applications are invited for a temporary post of either **RESEARCH ASSISTANT** or **RESEARCH FELLOW** in the above department. Applicants should be graduates with a good honours degree and, for appointment at Research Fellow level, should possess a Ph.D. degree. The successful candidate will be required to take part in a study of bone mineralisation in patients with chronic rheumatoid arthritis. Mineralisation of the femur will be measured by gamma-ray absorptiometry and total body-calcium by in vivo neutron activation analysis and the person appointed will be responsible for calibrating the equipment, making measurements, collating data and improving methods of data processing. Candidates should have knowledge of radiation physics and experience of programming large and small computers. The appointment will be made for a fixed term of three years.

Initial salary in the range £3,384 to £4,133 on either the 1B scale (Research Assistant) (£3,384 to £4,882) or the IA scale (Research Fellow) (£3,883 to £6,555) for Research and Analogous Staff. Both scales are currently under review.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 92/2. Closing date for applications: March 2, 1979.

9474(A)

UNIVERSITY OF MALAWI
THE POLYTECHNIC

Applications are invited for the post of

LECTURER IN PHYSICS

in the DEPARTMENT OF MATHEMATICS AND SCIENCE. Applicants should possess a good degree in Physics. An interest in Mathematics would be an advantage. Previous teaching experience will be an advantage but is not essential. Appointee will be required to teach Physics, Mechanics and Electrical Science to diploma level in the field of engineering.

Salary scale: Lecturer K3,500 to K6,600 p.a. (£1 sterling to K1.62). The British Government may supplement salary in range £3,450 to £3,654 p.a. (sterling) for married appointee and £2,340 to £2,544 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. If no British Government supplement is available, the University may pay an addition of between K1,320 to K1,656 p.a. for Lecturer grade (taxable in Malawi). Family passages; superannuation scheme; Gratuity 15% to 25%; biennial overseas leave; housing and various allowances. Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Malawi, PO Box 278, Zomba, Malawi by March 22, 1979. Applicants resident in UK should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9480(A)

UNIVERSITY OF WOLLONGONG
Australia

PROFESSOR— MATHEMATICS (Ref. No. 919)

Applications are invited for the above-mentioned positon which has become vacant following the retirement of the Foundation Professor of Mathematics, Professor A. Keane. Applicants may have interests in any field of Mathematics, but the University would welcome, in particular, applications from those with an interest in Applied Statistics.

Applications close **March 23, 1979.**

PROFESSOR/ASSOCIATE PROFESSOR—PSYCHOLOGY

Following the appointment of the Foundation Professor of Psychology, Professor A. M. Clarke, to the position of Deputy Vice-Chancellor, the University invites applications for this vacancy which may be filled by either: a Professorial appointment, including Chairmanship of the Department, for a limited term of four years (Ref. No. 005) or (b) a tenurable appointment at Associate Professor level, with the appointee being required to serve as Chairman of Department for a minimum period of four years. (Ref. No. 991).

Applicants may have interests in any field of Psychology, but the University would welcome, in particular, applications from those with interests in empirically oriented research in community, clinical (counselling and abnormal) or social psychology or the psychology of human learning.

Applications close **March 9, 1979.**

Salary per annum: Professor $A33,061; Associate Professor $A27,916.

Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill a Professorial or Associate Professorial vacancy by invitation.

For all positions, fares to Wollongong for the appointees and dependents are paid and a relocation allowance is payable. For a limited term appointment, the University would consider contributing to the cost of repatriation on conclusion of the appointment.

Applications should contain full details of qualifications, employment history, research interests, publications list, and the names and addresses of three referees, and should be forwarded to the Bursar, The University of Wollongong, Box 1144, P.O., Wollongong, N.S.W., 2500, Australia, from whom further information is available if required. Please quote the reference number of the position, and mark envelope "Confidential—Appointment". A copy of application should be sent to the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, from whom further information may also be obtained. 9539(A)

UNIVERSITY OF EDINBURGH
LECTURESHIP IN MICROBIOLOGY

Applications are invited for a newly established Lectureship in the Department of Microbiology. Applicants should have some experience or interest in applied microbiology, preferably in the area of agriculture or food.

Salary on scale £3,883 to £7,754 per annum, with superannuation benefits.

Further particulars may be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications by letter (five copies), including the names of three referees, should be lodged not later than March 7, 1979. Please quote Reference 1007.

UNIVERSITY OF CAMBRIDGE

LECTURESHIP

Applications are invited for a University Lecturer in Botany to take up appointment from October 1, 1979 or as soon as possible thereafter. The person appointed will be expected to provide teaching in the field of whole plant physiology and/or ecological plant physiology and to have research interests in the same areas of plant physiology. The appointment will be for three years in the first instance, with the possibility of reappointment to the retiring age. The salary is on an incremental scale rising from £5,367 to £8,257 per annum. Applications with the names of two referees should be sent by March 31, 1979 to the secretary of the Faculty Board of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, from whom further particulars may be obtained. 9531(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF FOOD SCIENCE

Applications are invited for a temporary post of RESEARCH FELLOW in the above Department. Applicants should have a Ph.D. degree, preferably in biochemistry or chemistry, and have an interest in applying their knowledge to the biochemistry of foods or to the chemistry of food additives. The successful applicant will have opportunities to cooperate with research institutes and to help with departmental teaching. The appointment will be made for a fixed period of three years.

Salary on the IA scale for Research and Analogous Staff (£3,883 to £6,555) (under review) according to age, qualifications and experience.

Interested persons who wish to discuss the post in more detail or visit the Department should contact Professor David S. Robinson (0532 31751, ext. 540).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 72/3/D. Closing date for applications, March 16, 1979.

9473(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of LECTURER in the above Department. The person appointed will participate in teaching biochemistry to science and to medical students. The Department provides good facilities and opportunities for research. The appointment will date from October 1, 1979.

Salary on the scale for lecturers: £3,883 to £7,754 (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/71/D. Closing date for applications, March 12, 1979.

9367(A)

UNIVERSITY OF ZAMBIA

Applications are invited for 2 posts of

SENIOR LECTURER/ LECTURER IN ORGANIC CHEMISTRY

in Department of Chemistry. Applicants should have a Ph.D. or equivalent and show evidence of research ability. The appointees would be expected to teach at all levels, from first-level to post-graduate courses and to participate in Departmental Research Programmes.

Salary scales: Senior Lecturer K7,608 to K8,016 p.m. Lecturer K5,904 to K7,608 p.a. (£1 serling=K1.56). The British Government may supplement salary in range £2,922 to £4,350 p.a. (sterling) for married appointees or £930 to £1,968 p.a. for single appointees (reviewed annually and normally free of all tax) and provide children's education allowance; superannuation; medical aid scheme; regular overseas leave; three year contract. Detailed application (2 copies) with curriculum vitae and naming 3 referees to be sent to Regisrar, University of Zambia, PO Box 2379, Lusaka, Zambia by March 16, 1979. Applicants resident in the UK should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9483(A)

CHARING CROSS HOSPITAL

BASIC GRADE BIOCHEMIST

Applications are invited from honours graduates for the above post in the Department of Chemical Pathology.

This is a busy, highly automated department with computerised data handling and the successful applicant will be expected to participate in all aspects of the routine work.

Previous experience and/or higher qualifications in clinical chemistry would be an advantage, but are not essential. Study for further qualifications will be encouraged.

Informal enquiries and requests to visit the department should be directed to Dr O. Swale (Tel: (01) 748 2040 ext 2779 or 2772). Whitley Council conditions of employment apply. Salary scale £3840—£4629 per annum inclusive. Application forms from District Personnel Department, Charing Cross Hospital, Fulham Palace Road, Hammersmith, London W6 Tel: (01) 748 2040 ext 2992/3021.

Closing date for receipt of applications 1 March 1979. 9499(A)

MEDICAL RESEARCH COUNCIL

RADIOBIOLOGY UNIT

A SCIENTIST

is required to join a team studying the distribution and effects of radioactive materials in animals. The appointee will initially be concerned with studies on the distribution and dosimetry of radionuclides in tissues but other interests in radiobiology will be encouraged. Applicants should preferably be well qualified in physics or biology and have at least 3 years postgraduate experience in research. Experience in the use of computers would be an advantage.

Salary in accordance with age and experience on M.R.C. Grade II/I, £3,883 to £7,754 (as at October 1, 1978, with negotiations in progress).

Enquiries or application with curriculum vitae and names of two referees to **Dr J. Vennart, Director, M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD,** by March 9, 1979.

FELLOWSHIPS

RESEARCH FELLOWSHIP

Firemen's Health Research – Monitoring of ECG and other studies

Scientific Advisory Branch
Horseferry House, London, SW1

Senior/Junior Research Fellow

The successful candidate will be appointed to help carry out measurements of heart rate and other physiological functions as part of a work programme investigating stress in firemen's work. The officer will help in planning and developing a study programme for ECG measurement on groups of active firemen and for implementing and maintaining the measurement procedures.

The officer will form part of a small team working on a number of aspects of the health of firemen and will be responsible to a Senior Scientific Officer concerned with the research planning of the team.

The applicants should have an honours degree or equivalent in human physiology with some practical experience in the use of physiological apparatus and the measurement of cardiac and respiratory function. A background in physics and chemistry would be an advantage.

Some travel will be necessary.

The fellowship will be tenable for two years and remuneration will be on the scale £3695-£4580 for Junior Research Fellow and £5092-£6216 for Senior Research Fellow.

Apply in writing by 16th March, 1979 to Miss S. M. Swinborne, Room 203, Whittington House, 19-30 Alfred Place, London WC1E 7EA.

9477(E)

Home Office

FELLOWSHIPS—continued

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)
WATFORD ROAD, HARROW
MIDDX. HA1 3UJ

M.R.C. TRAINING FELLOWSHIPS

Applications are invited from suitably qualified graduates to work in any one of the following areas:

1. Immunochemical analyses of serum immune complexes, in particular those occurring in E.B. virus infections (infections mononucleosis) and mycoplasma pneumoniae infections. It is also planned to investigate the possible role of auto-anti-idiotypes in the control of the anti-host tissue antibodies (e.g. crythrocyte autoantibodies) in these infections.
2. The neuropathology of mental disease.
3. Immunopathology of C.N.S. receptors.
4. Applications of immunological methods to clinical problems.

Eligibility requirements: From post-registration up to senior registrar or equivalent academic levels PHD/D.PHL. or MSC plus at least 3 years postgraduate experience.

Tenure: Up to three years.

Stipend: On the current NHS medical (House Office to Senior Registrar) or current relevant academic scale.

The successful applicants will be required to apply for a medical research training fellowship through the normal annual competition for these awards.

Please send curriculum vitae to Mrs J. Tucker-Bull by **FEBRUARY 16th.**

9545(E)

UNIVERSITY OF SASKATCHEWAN

GERHARD HERZBERG FELLOWSHIPS FOR GRADUATE STUDY

In honours of Dr Gerhard Herzberg, 1971 Nobel Laureate in Chemistry, and to commemorate his service to Saskatchewan, the University of Saskatchewan offers a graduate fellowship valued at $7,000 per annum, renewable for a second year. Herzberg Fellows are eligible for a part-time laboratory demonstratorship which provides additional remuneration up to $2,000 per annum.

The fellowship is tenable in the Department of Physics or the Department of Chemistry and Chemical Engineering by a candidate for a graduate degree in spectroscopy or a related field.

Letters of application with appropriate documentation and the names of two referees should be addressed to the Dean, College of Graduate Studies and Research, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0. Applications for Fellowships for the 1979-80 academic year should be made prior to March 15, 1979.

9485(E)

RESEARCH FELLOWSHIP

IMPERIAL CANCER RESEARCH FUND

We have a vacancy for a postdoctoral Research Fellow to join a working group on markers of neoplastic transformation during ageing and carcinogenesis *in vitro*, in epithelial cell systems. The specific collaborative project will be concerned with isolation of hybrids, using irreversible biochemical inhibitors, identification of transformed characters and the association of these characters to DNA and chromosome changes. Special experience in cell culture or cytogenetic techniques required.

Appointment will be for three years. Salary according to qualifications and experience.

Further information from Dr L. M. Franks (01-242 0200, ext. 211). Applications with curriculum vitae and names of two referees should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX.

9555(E)

FELLOWSHIPS—continued

LANCHESTER POLYTECHNIC

Coventry

Department of Biological Sciences

Postdoctoral Research Fellowship

(Tenable for up to 3 years from March 1, 1979)
£4,101 - £6,558

THE JOB · The project is funded jointly by the SRC and ICI and involves the development of a method for the *in vitro* culture of perifused hepatocytes supported in a 3-dimensional matrix and its application to toxicological studies

REQUIRED Experience in animal cell culture and biochemistry Knowledge of cytological procedures would be an advantage

For further Information applicants may contact Dr Sturdee or Dr Crisp by telephoning Coventry (0203) 24166

Faculty of Applied Science

Research Assistant in Cardiac Pacing

(Tenable for 1 year from March 1, 1979)
£3,192 - £3,330

THE JOB · A statistical survey of patients with artificial cardiac pacemakers is required to attempt to identify those factors which cause a rise of stimulation threshold in certain patients The required collection of data will involve close collaboration with cardiac pacing centres in a number of hospitals

REQUIRED · Applicants should have either an appropriate Honours Degree, or an appropriate HNC plus relevant experience

For further Information applicants may contact Dr. Economides or Dr Duckers by telephoning Coventry (0203) 24166

For application forms and further particulars for the above posts please apply in writing enclosing a foolscap stamped and addressed envelope to the Personnel Officer, Lanchester Polytechnic, Priory Street, Coventry CV1 5FB, applications returnable by February 19, 1979 8404(E)

RESEARCH FELLOWSHIP

Imperial Cancer Research Fund Laboratories,
Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in Drosophila melanogaster, using cloned DNA fragments to investigate their organisation and expression. Experience in molecular biology desirable.

Appointment will be for three years. Salary with entry according to qualifications and experience within range £5,332 to £6,530.

Further information from Dr Ish-Horowicz (01-959 3236) Applications with curriculum vitae and names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields WC2A 3PX by February 24, 1979.

History of Medicine Fellowships

The Wellcome Trust provides grants for research in the history of medicine and maintains Wellcome Units for the History of Medicine in the Universities of London, Oxford and Cambridge, the Wellcome Institute for the History of Medicine in London, and also provides support for a small Unit at Edinburgh University.

Applications are invited for research fellowships of up to three years, to be held in the Wellcome Units or the Wellcome Institute. Applicants must hold a doctoral degree or an equivalent qualification and have a background in history, science or medicine. Applicants should write in the first instance, outlining their research proposals and enclosing their *curriculum vitae*, to the Director of the Unit in which they wish to work. The addresses of the Units are as follows, and letters should arrive **not later than 1st March:**

**The Wellcome Institute for the History of Medicine,
183 Euston Road, London NW1 2BP.**

Wellcome Unit for the History of Medicine, 47 Banbury Road, Oxford OX2 6PE.

Unit of History of Medicine, University College London, Gower Street, London WC1E 6BT.

Wellcome Unit for the History of Medicine, Free School Lane, Cambridge CB2 3RH.

The Wellcome Lecturer in the History of Medicine, Department of History, University of Edinburgh, William Robertson Building, George Square, Edinburgh EH8 9JY.

If the Director of the academic unit concerned agrees to support the proposal, it will be forwarded to the Wellcome Trust for a decision on whether a fellowship can be awarded. Applicants should write to their first choice only. If unsuccessful, the application may be passed to other Units if the candidate requests it.

THE WELLCOME TRUST

1 Park Square West, London NW1 4LJ 9508(E)

APPLICATIONS
are invited for

CHARLES A. REVSON FELLOWSHIPS
at
THE HEBREW UNIVERSITY OF JERUSALEM

The Fellowships are being offered in the Faculties of Agriculture, Science and Mathematics, Medicine and Dental Medicine (in the pre-clinical areas) and the Schools of Pharmacy and Applied Science and Technology

The Fellowships, which will be awarded to outstanding scholars for a period of three to four years, are mainly at the *rank of lecturer* with a limited number also available at the rank of senior lecturer or above. Fellows will be required to carry out teaching and research in one of the above fields

Applicants should be residents of Israel or persons intending to settle in Israel.

Appointments will be made as from July 1979 and not later than October 1980 Academically suitable Charles A. Revson Fellows will be offered posts as regular faculty members at the Hebrew University of Jerusalem on completion of their Fellowships

Applications accompanied by a full curriculum vitae, list of publications, reprints of three recent publications, names of referees and date of availability, should reach the Academic Secretary, The Hebrew University of Jerusalem, Israel, by March 15, 1979. 9552(E)

FELLOWSHIPS—continued

DEPARTMENT OF
VETERINARY PHYSIOLOGY

UNIVERSITY OF EDINBURGH

S.R.C. funded postdoctoral research fellowship to join a group working on somatosensory mechanisms in the mammalian spinal cord. Tenable for three years, starting salary scale point 3 on range 1A national research salary scale. Candidates should be experienced in neurophysiological techniques. Experience in laboratory-oriented computing will be an advantage.

For further information contact Professor A. Iggo, Department of Veterinary Physiology, Royal (Dick) School of Veterinary Studies, Edinburgh EH9 1QH.

Applications, by letter (two copies), giving the names of two referees, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, not later than March 2, 1979. Please quote reference 5003.

UNIVERSITY OF ABERDEEN

DEPARTMENT OF
BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP/ ASSISTANTSHIP

(Re-advertisement)

Applications are invited for an S.R.C. Research Fellowship to determine the amino acid sequence of pyruvate kinase. The project is a collaborative one with the protein crystallography group at the University of Bristol, and will lead to a detailed description of the molecular structure of pyruvate kinase.

The successful applicant will work, in collaboration with a predoctoral research assistant already in post, with Dr L. A. Fothergill's research group which is currently studying the structures of four other glycolytic enzymes.

The appointment is available for a period of up to three years. Salary within Range 1A, £3,883 to £4,882 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by March 2, 1979.

9576(A)

New Zealand

UNIVERSITY OF CANTERBURY

Christchurch

Applications are invited for a University

POSTDOCTORAL FELLOWSHIP

in the following Department. Applicants should possess a Ph.D. or equivalent degree, preferably followed by some research experience. The appointee may be asked to undertake a limited amount of teaching in addition to contributing to the current research programme in their particular field:

BOTANY: The fields within which the Fellowship may be held are: Reproductive biology of flowering plants; Soil biomass studies; Fine structure and taxonomy of marine nanno plankton.

Applications close on **March 31, 1979.**

The emolument will be NZ$8,500 per annum. Fellowships are tenable for one year.

Further particulars and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

9592(E)

MONASH UNIVERSITY

Melbourne, Australia

POSTDOCTORAL FELLOWSHIP IN ECOLOGY-ANIMAL/PLANT INTERACTIONS

The University is offering a 2 year appointment to initiate studies in a local, natural ecosystem, with primary emphasis on the relationships between fauna and flora. Examples of possible fields of study are ant/eucalypt interactions, litter decomposition, plant/herbivore systems, etc. The appointment is jointly in the Department of Botany and Zoology. Applications should include a general statement of the proposed research. Salary: Junior Research Fellow $A13,083 p.a. Travelling and removal allowance. Assistance with temporary housing. Applicants should quote reference No. 43065 Closing date:: **February 28, 1979.**

Applications in duplicate to the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria, Australia 3168 giving age, qualifications, experience and names and addresses of three referees.

9540(E)

THE UNIVERSITY OF HULL

DEPARTMENT OF
APPLIED PHYSICS/PHYSICS

Applications are invited for three research fellowships, which are immediately available, for a period of up to three years.

Department of Applied Physics

1. A research fellow is required to measure the frequency characteristics of the current generation of pulsed CO_2 lasers and to devise ways of improving their frequency stability using techniques such as hybridisation and injection locking.
2. A research fellow is required to work on the use of timable multi-atmosphere, molecular gas lasers for the remote sensing of trace gases in the atmosphere.

Department of Applied Physics/
Physics

3. A research fellow is required to investigate the use of ion implantaiont for fabricating fast, photovoltaic, infrared detectors in materials such as HgCdTe.

These fellowships are suitable for graduates with at least three years' research experience in the fields of optics and quantum electronics (for 1 and 2) and solid state physics (for 3).

Salary scale: £3,883 to £6,555 per annum (under review).

Applications should give full details of education, qualifications and research experience, together with the names of two referees, and should be sent by February 22, 1979 to Dr. E. L. Thomas, Department of Applied Physics, The University of Hull, Hull HU6 7RX from whom further details may be obtained. 9520(E)

UNIVERSITY OF BRISTOL

SCHOOL OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP IN LASER SPECTROSCOPY AND KINETICS

Applications are invited for a Postdoctoral Research Fellowship to work on the electronic spectroscopy and state to state kinetics of free radicals. The project will make use of both continuous wave and pulsed dye lasers and an inert gas halide laser, and will be oriented to problems of astrophysical importance. The post is S.R.C. funded, and the initial salary will be in the range £3,883 to £4,382 p.a. (scale under review). Applicants should send a curriculum vitae and the names of two referees to Professor R. N. Dixon, School of Chemistry, The University, Bristol BS8 1TS, U.K.

9533(E)

THE ANIMAL VIRUS RESEARCH INSTITUTE

Pirbright,
Woking, Surrey GU24 0NF

Applications are invited for a

WELLCOME RESEARCH FELLOWSHIP

tenable for 3 years. The successful candidate will investigate the physical and chemical structure of picornaviruses with the aim of ascertaining those factors which determine the stability of the capsid structure of foot-and-mouth disease virus. Applicants should preferably hold a Ph.D. degree and have had previous experience in virology and protein chemistry but students graduating this year are invited to apply. Opportunity will be provided to study for a higher degree.

Tax free stipend £4,000 p.a. for Ph.D.; £3,000 p.a. for new graduate.

Applications to the Secretary from whom further details can be obtained.

Closing date: March 15, 1979.

9595(E)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF
CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from graduates in Chemistry or Physics to work wih Dr J L Duncan and Dr D C McKean on Infra-red Spectroscopy. The successful applicant will undertake research on a variety of topics using a computer controlled, high resolution Fourier transform spectrometer. Previous interactive experience wih computers, and an ability to develop software and undertake electronic maintenance is desirable.

The post is funded by the Science Research Council and is available from April 1979. Appointment will be for one year in the first instance, with possible extension up to a maximum of three years.

Commencing salary within Range 1A, £3,883 to £4,382 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen with whom applications (two copies) should be lodged by February 23, 1979.

9506(E)

ASSISTANTSHIPS

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF INORGANIC,
PHYSICAL AND INDUSTRIAL
CHEMISTRY

THEORY OF VIBRATIONAL PHENOMENA IN ADSORBATES

Applications are invited for an S.R.C. postdoctoral Senior Research Assistantship at an initial salary of between £3,883 and £4,382 per annum, with superannuation benefits. The post is tenable for one year in the first instance, and may be renewed for a further year. The project is the theoretical study of vibrational phenomena in adsorbates including elec energy loss spectroscopy, with Professor T. B. Grimley. The successful applicant will join an active group involved in the theoretical study of molecular and electronic processes on solid surfaces.

Applications stating age, academic qualifications and experience, together with the names of two referees should be received not later than March 5, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: 479/N. 9522(P)

UNIVERSITY OF CALGARY

GRADUATE ASSISTANTSHIPS

(Teaching and Research)

Available for students proceeding the M.Sc. and Ph.D. degrees in a branches of CHEMISTRY and BIO CHEMISTRY. The assistantships a valued at $7,000 to $8,000 p.a. a include remission of program fee Travel allowance also available.

For further information write to:

Department of Chemistry
Chairman of Graduate Studies
UNIVERSITY OF CALGARY
Calgary, Alberta, Canada
T2N 1N4

Please indicate field of interest.

9462(P)

UNIVERSITY OF HULL

DEPARTMENT OF
APPLIED PHYSICS

RESEARCH ASSISTANTSHI NON DESTRUCTIVE TESTING

Applications are invited for a r search assistantship tenable for a perio of up to two years in the first instanc with the possibiliy of renewal. Th research assistant will be involved i the study of magnetic particle inspec tion testing and ultrasonic testing of wide variety of industrial component in collaboration with the Health an Safety Executive, Nuclear Inspecto rate.

Salary scale: £3,384 to £4,882 (unde review) together with USS benefits.

Applications, which should includ the names of two referees, should b sent as soon as possible, to Dr S Palmer, Department of Applied Ph sics, The University of Hull, Hul HU6 7RX from whom further part culars may be obtained.

9465(P)

THE HATFIELD POLYTECHNIC

PO Box 109,
Hatfield, Herts. AL10 9AB

SCHOOL OF NATURAL
SCIENCES

RESEARCH ASSISTANTSHIPS

POST 1 MAMMALIAN PHYSIOLOGY Ref: 167

There is an immediate vacancy for a suitably qualified graduate to work for a higher degree on non-adrenergic and non-cholinergic transmission on the rat gastric corpus. The post is tenable for two years in the first instance with possibility of extension for a third year.

For further details apply to Dr K. Wilson, Biological Sciences, Telephone Hatfield 68100, extension 483.

POST 2 ASTRONOMY AND EARTH SCIENCES GROUP Ref: 168

Applications are invited from graduates with an honours degree in geology to work on a contract to investigate rock weathering sponsored by the Overseas Unit of the Transport and Road Research Laboratory. An interest in applied petrology would be an advantage.

The appointment will be for an initial period of two years with the possibility of an extension for a further year. The person appointed would be expected to register for a higher degree.

The successful candidate will be expected to take up the post on April 1, 1979, or as soon as possible thereafter.

Informal enquiries to Dr D. Cawsey, Hatfield 68100 extension 283, or write or telephone the Staffing Office, extension 309.

Salary scale for both posts (which are superannuable): £2,613 to £2,700 to £2,787 per annum plus £159 local weighting.

Closing date: February 26, 1979.

9530(P)

ASSISTANTSHIPS—cont.

PHILIPPS-UNIVERSITY MARBURG

DEPARTMENT OF PHARMACOLOGY

SCHOOL OF MEDICINE AND HUMAN BIOLOGY

Applications are invited for a two-year **POSTDOCTORAL RESEARCH ASSISTANTSHIP** (DFG, BAT II) for work with Dr G. F. Fuhrmann on problems of yeast plasma membrane vesicles—structure and function. Applicants with interest in membrane research and pharmacology should write to: Professor Dr G. F. Fuhrmann, Department of Pharmacology, Philipps-University Marburg, Lahnberge, D-3550 Marburg, Germany. 9584(P)

STUDENTSHIPS

GLASSHOUSE CROPS RESEARCH INSTITUTE

invites applications for an

AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

enable at the Institute for three years or work on the potential of the insect-pathogenic muscardine fungi to control hrips and leafhoppers. Minimum qualification first or upper second class honours degree in biological subjects with emphasis on microbiology, particularly mycology. Interest in biological pest control desirable.

Application forms and further particulars obtainable from Secretary, G.C.R.I., Worthing Road, Rustington, Littlehampton, Sussex BN16 3PU. Closing date for applications February 26. 9549(F)

AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

Applications are invited for an A.R.C. postgraduate studentship tenable at the Meat Research Institute for research into the viscoelastic properties of semi-solid foodstuffs.

The work will involve a study of he transmission of mechanical pulses hrough foods and computer analysis of transient sresses generated with an Instron materials tester.

The project is expected to form the basis for a Ph.D. thesis at the University of Bristol and the appointment will commence in October 1979.

Candidates should possess a First or Upper Second Class degree in Physics or a related subject.

Further particulars of the award and allowances together with application forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol BS18 7DY. 9484(F)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington, Cambridge CB2 2LQ

CYTOGENETICS/PHYSIOLOGY DEPARTMENTS

POSTGRADUATE STUDENTSHIP

Applications are invited for an Agricultural Research Council postgraduate studentship leading to a Ph.D. in the University of Cambridge October 1979, to work on the genetics and biochemistry of protein components relating to bread quality in wheat. The student required should hold a first or upper second class honours degree in a biological science in which genetics and biochemistry feature strongly.

Remuneration will be in accordance with the Agricultural Research Council Regulations Governing Postgraduate Awards.

Applications together with a curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting reference CYT/48, as soon as possible. 9493(F)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

RESEARCH STUDENTSHIPS

Studentships, commencing in October for postgraduate work leading to a higher degree in London University, may be available later in the year for research on several topics, including the structure and function of membranes. Enquiries from interested final year undergraduates should be addressed to Professor J.A. Lucy, Department of Biochemistry and Chemistry, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. 9471(F)

HAMILTON KERR INSTITUTE

University of Cambridge

STUDENTSHIPS IN THE CONSERVATION OF EASEL PAINTINGS

Applications are invited from men and women preferably between the ages of 20 and 25 for one studentship of three years duration starting September 1979 with an optional fourth year internship in an approved context. Admission for a shorter period will be considered from partly trained students transferring from their conservation courses.

The Institute is fully equipped with studios, a workshop and scientific laboratories. There is a technical and art-historical library; the libraries and scientific facilities of the University (including the Fitzwilliam Museum) are also available. The students play an active part in the Institute, and there are also courses in theoretical and academic instruction. Students are normally eligible for membership of a College.

A student should normally have a first degree or equivalent qualification or experience in relevant subjects such as The Sciences, Medicine, or Fine Arts. Evidence of manual and artistic skills is essential.

Fees chargeable by the Institute are £750 p.a. for UK and £850 p.a. for overseas residents. A successful UK applicant may be eligible for a state grant for which the Institute itself would apply to the Department of Education and Science. In the case of a state grant being awarded the fees are payable by the DES.

Application forms together with the Institute's prospectus may be obtained from:

The Secretary
Hamilton Kerr Institute
Whittlesford
Cambridge CB2 4NE

The closing date for receipt of candidates application forms is March 23, 1979. 9491(F)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF FIBRE SCIENCE

RESEARCH STUDENTSHIPS

Applications are invited from suitably qualified science or engineering graduates for two studentships. One for work on the handle and texture of fabrics would suit a candidate with a physics/mathematics background. The other dealing with fibre structure/property relationships would suit a chemist or materials scientist.

S.R.C. scales will apply and successful applicants will be expected to register for a higher degree.

Further information and application forms can be obtained from:

Dr H. M. Elder,
Chairman of Department,
Department of Fibre Science,
University of Strathclyde,
George Street, Glasgow.

9572(F)

INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

A.R.C. POSTGRADUATE STUDENTSHIPS

Applications are invited from students interested in research in the field of animal diseases.

Candidates should have studied biological science, with particular interests in biochemistry, physiology, bacteriology or zoology and will be required to register for a higher degree, usually at the University of Reading.

Candidates should have, or expect soon to obtain, a 1st or Upper Second class honours degree in a relevant subject.

The Institute is situated in a pleasant rural area with a Staff Restaurant and good recreational facilities. If required, accommodation for a single person could be provided in the Institute's Hostel.

The Agricultural Research Council's pension scheme is non-contributory.

Application Forms from: Secretary, Agricultural Research Council, Institute for Research on Animal Diseases, Compton, Nr. Newbury, Berks., quoting Ref. 400. 9517(F)

MISCELLANEOUS

F.D.A. FOREIGN BODY CARCINOGENESIS STUDY

The Food and Drug Administration plans to conduct a study to distinguish the chemical carcinogenic potential of implant materials from their ability to induce tumours as a result of their surface characteristics (foreign body carcinogenesis). The in vivo study will be for a twenty-four (24) month period using rats or any other appropriate animal model. The contractor should have experience in carcinogenesis studies, particularly those involving modern cytogenetics, pathology, hematology and tissue culture techniques. Requests for RFP No. 223-79-5061 should be directed to Beverly Lott, Department of Health, Education and Welfare, Public Health Service, Food and Drug Administration, HFA-514, 5600 Fishers Lane, Rockville, MD, 20857. 9583(J)

GRANTS & SCHOLARSHIPS

POSTGRADUATE RESEARCH

DEPARTMENT OF BIOLOGY

PRINCETON UNIVERSITY

N.I.H. postdoctoral training grant positions for recent Ph.D.'s in the areas of biochemical and genetic aspects of cell differentiation (Drs T. Cline, E. Cox, A. Newton, P. Schedl), cell biology and development (Drs J. Bonner, E. Cohen, M. Steinberg, G. Witman), and behavioural and population genetics (Drs J. Endler, J. Gould, R. May, W. Quinn) are available beginning summer, 1979. Applications should include curriculum vitae and summary of research interest.

Closing date April 2, 1979. Inquiries or applications should be sent to Dr E. C. Cox, Chairman, Department of Biology, Princeton University, Princeton, N.J. 08540.

Princeton University is an Equal Opportunity/Affirmative Action Employer. 9388(H)

THE NATIONAL KIDNEY RESEARCH FUND invites applications for grants for renal research at units within the United Kingdom. Application forms are available from The Secretary, 184B Station Road, Harrow, Middlesex HA1 2RH (01-863 4469). 9408(H)

FOR SALE & WANTED

FOR SALE: Annual Reports of Progress of Applied Chemistry, 1941–1973 plus various other books on water (new and second-hand). Offers to: Box No. 9588(L), Nature, 3 Dyers Buildings, Holborn EC1N 2NR. 9588(L)

SYMPOSIA

PROSTAGLANDINS AND INFLAMMATION

An International Research Symposium

will be held at King's College Hospital Medical School, London, on Thursday and Friday, August 2 and 3, 1979.

Further details and registration form from:

Dr A. W. Ford-Hutchinson,
Biochemical Pharmacology
Research Unit,
King's College Hospital
Medical School,
Denmark Hill,
London SE5 8RX.
Tel: 01-274 6222, Ext. 2026.

COURSES

UNIVERSITY OF ESSEX

DEPARTMENT OF BIOLOGY

M.Sc. COURSE: GENE TECHNOLOGY IN MICROORGANISMS

Applications are invited for the above 1 year course for October 1979. A limited number of studentships may be available. The course is designed to acquaint the student with the techniques of classical microbial genetics, and in vitro recombinant DNA techniques. Enquiries should be addressed to The Chairman, University of Essex, Department of Biology, Wivenhoe Park, Colchester, CO4 3SQ. 9510(D)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

CENTRE FOR ENVIRONMENTAL TECHNOLOGY

M.Sc. IN ENVIRONMENTAL TECHNOLOGY 1979/80 ENERGY POLICY

One of the specialist options being offered as part of the one year Postgraduate and Post Experience Course at the interdepartmental Centre for Environmental Technology at Imperial College.

Course starts with a series of core subjects covering physical environment, applied ecology, urban technology, mineral resources, energy, environmental economics and policy, operations research, computing, and sources and choices of technology.

In the second term students specialise in one of six options. The Energy Policy option is designed to provide an understanding of the technological and political priorities of the energy industries and the sector as a whole; emphasis is placed on the relationship between the technology and the other considerations.

The remainder of the year is devoted to a research project. Projects in conjunction with outside bodies are welcomed.

Course is open to science and engineering graduates and other suitably qualified students, both from UK and overseas. Post experience students may divide the course between two academic years.

N.E.R.C., S.R.C. and S.S.R.C. have approved the course for tenure of their advanced course studentships.

Closing date for applications: April 1, 1979.

Further particulars from the Registrar, Imperial College of Science and Technology, London SW7 2AZ. 9512(D)

NATO/EMBO

INTERNATIONAL SUMMER SCHOOL on

NUCLEIC ACID PROTEIN RECOGNITION

Aug. 20 - Sept. 2, 1979 - Island of Spetsai, Greece

Lectures and discussions in English will cover the following topics:

1) Techniques for studying nucleic acid protein recognition.
2) Organization of genes in DNA.
3) DNA protein interactions (nucleosomes and proteins involved in RNA transcription).
4) RNA protein interactions (viruses and proteins involved in translation).
5) Theoretical aspects of nucleic acid protein recognition.

The lecturers will include:

H. Bujard (Germany), **C.R. Cantor** (USA), **P. Chambon** (France), **B.F.C. Clark** (Denmark), **B.S. Cooperman** (USA), **H. Delius** (Germany), **J.P. Ebel** (France), **W. Gilbert** (USA), **D. Glover** (UK), **F. Gros** (France), **M. Grunberg-Manago** (France), **C. Hélène** (France), **J. Hershey** (USA), **A. Klug** (UK), **P. Little** (UK), **A. Rich** (USA), **R.J. Roberts** (USA), **V. Sgaramella** (Italy), **T. Steitz** (USA), **P.H. Von Hippel** (USA), **C. Weissmann** (Switzerland), **H. Zachau** (Germany).

The Summer School will be suitable for predoctoral students and for post-doctoral workers in related fields.

Applications should be sent to **Dr. M. Buckingham (Dept. of Molecular Biology, Pasteur Institute, 25, rue du Docteur-Roux, 75015 Paris France)** as soon as possible and not later than **May 1, 1979.** They should contain a curriculum vitæ including the applicant's scientific background and interests and one letter of recommendation. The applicants will be informed before June 1 whether they have been accepted. A registration fee of $80 will then be required. Participants will have to pay for their travel expenses. Student accommodation, breakfast and lunch will be provided without charge.

The organizing Committee

M. Buckingham (France), **J.P. Ebel** (France), **A.E. Evangelopoulos** (Greece).

Lively, readable and reliable, British Birds is the monthly journal for all British and Irish birdwatchers, professional and amateur alike. An internationally respected scientific journal, issues of British Birds build into a valuable reference work.

For a year's subscription send your name address, and £12 (overseas US $19.50 in any currency at the current exchange rate) to Macmillan Journals Ltd., Subscription Dept., Brunel Road, Basingstoke, Hampshire RG21 2XS.

A free copy is available from the above address.

British Birds

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US $1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

Microbiological Research Establishment

Bacterial Cell Pastes

Escherichia coli MRE 600
The original ribonuclease free strain, buffer washed.
(Minimum quantity 2kg @ £190)

Bacillus stearothermophilus NCA 1503
Grown at 60°C the source of many thermostable enzymes.
(Minimum quantity 1kg @ £224)

Escherichia coli RY 13
Contains restriction endonuclease Eco R1 and Eco R1'.
(Minimum quantity 2kg @ £190)

Thermus aquaticus YT-1
Grown at 70°C, the source of thermostable enzymes including restriction endonuclease Taq YI.
(Minimum quantity 0·5kg @ £280)

Escherichia coli B
A source of ribosomes, DNA polymerase I, RNA polymerase, DNA ligase and exonuclease III.
(Minimum quantity 2kg @ £190)

Clostridium pasteurianum W5
Grown at 30°C, a source of ferredoxin.
(Minimum quantity 0.5kg @ £168)

All these products can be supplied to overseas customers.
69 other types of cell paste are also available.

The listed products are offered at the quoted sterling prices, which remain firm until 31 March 1979, subject to availability. Prices include packing in dry ice, and delivery on UK orders, which are subject to VAT at ruling rates. Overseas orders are subject to transport charges at cost. For listed items please send your official order to the:

Microbial Products Section,
Microbiological Research Establishment,
Porton, Salisbury, SP4 0JG, Wiltshire, UK.

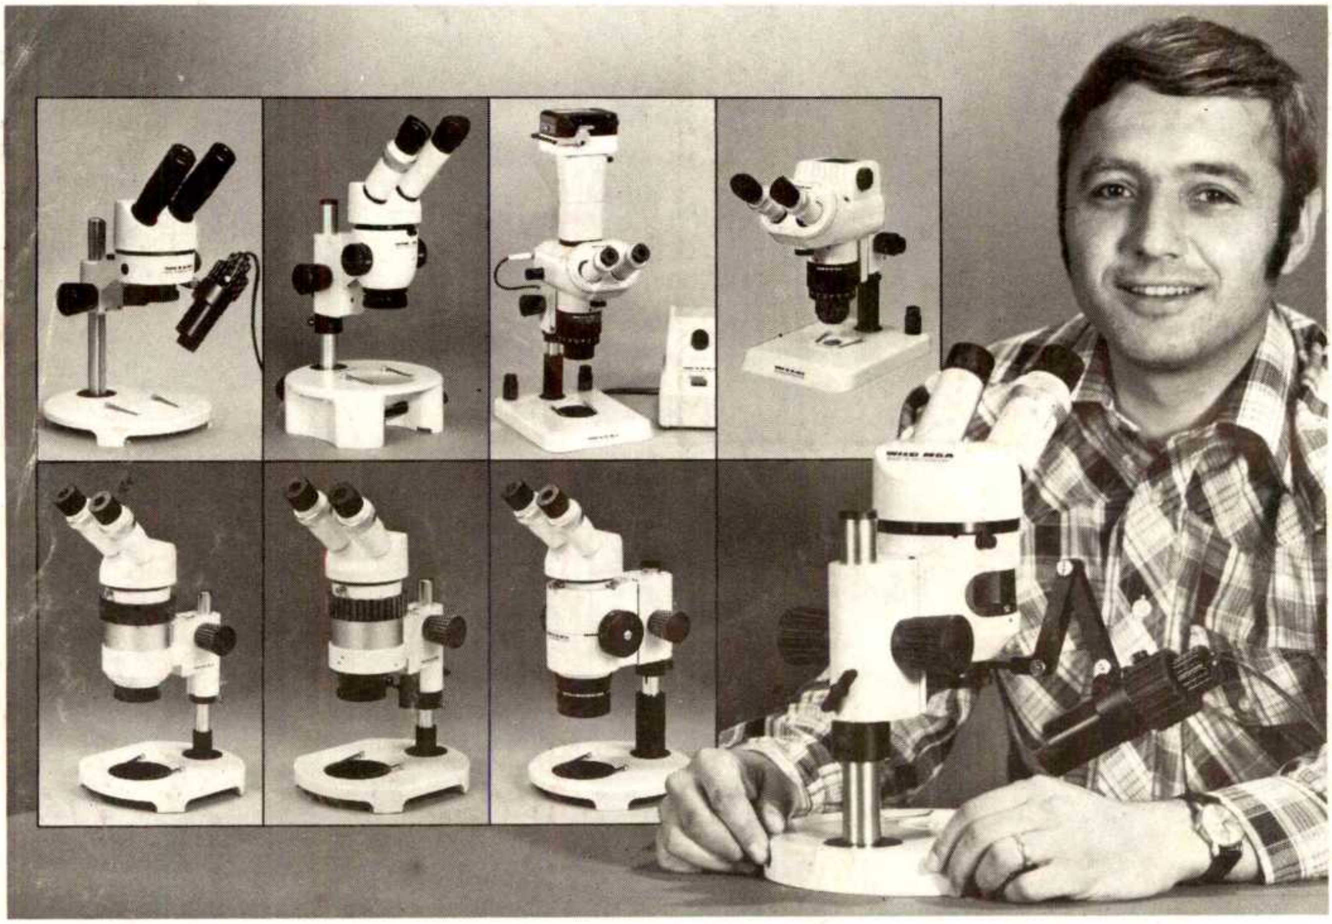
19 JUN 1979

The choice of the best.



It just had to be a Wild instrument. They're optically and mechanically tops, world wide. And if I want to use a special technique, there'll certainly be a suitable additional set of accessories.
But what a range of stereomicroscopes! The Wild consultant soon showed me the differences between them. There's the **Wild M1A** for process and control work in industry; the Wild **M1B** for educational work; the **Wild M3,** with three-step magnification changer, for the laboratory. The **Wild M5A** has the greatest magnification range – up to 250× with its coaxial illuminator. And then come the zoom stereomicroscopes; the **Wild M7A** with stepless variation of magnification within the range 1:5; the **Wild M7S,** specially for photomicrography and polarisation; and the **Wild M8,** with 1:8 zoom range. And, if you want to photograph in the macro range, you'll certainly be enthralled by the **Wild M400 Photomakroskop**. But to examine highly-reflecting surfaces or thin layers, the **Wild M450 Epimakroskop** is the answer. Ask for brochure M1 180e.

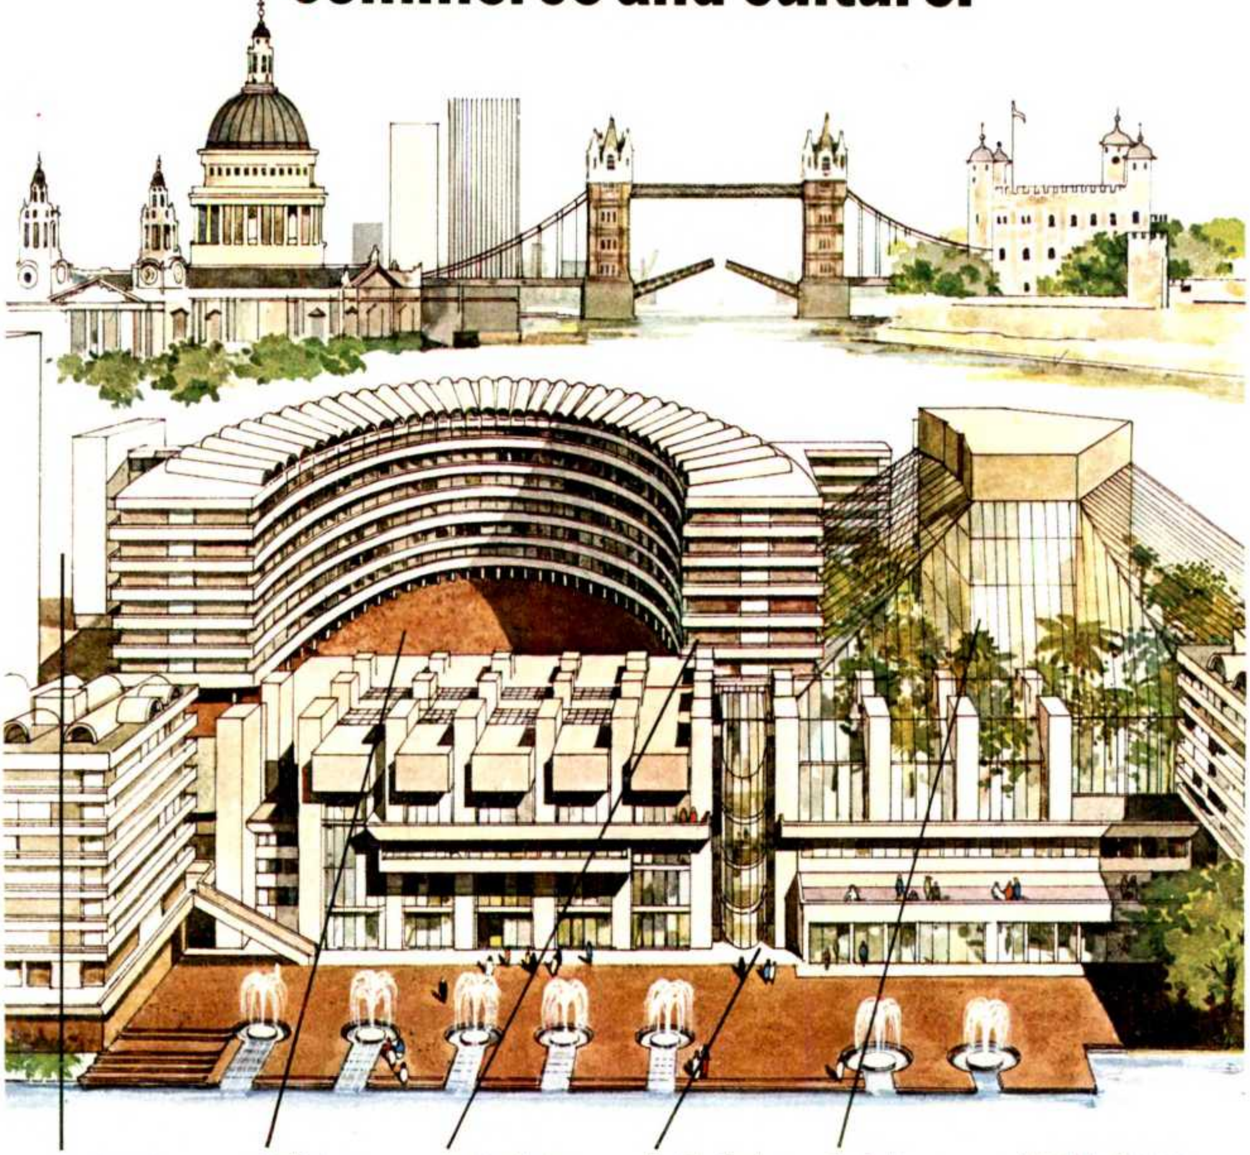
Deep-sea sulphide deposits

The new Barbican Centre is much more than one of the most modern conference centres in one of the world's most historic cities. It's an Arts Centre, too.

For example, the Royal Shakespeare Company will have its new permanent home in the Barbican. So will the London Symphony Orchestra. And the Guildhall School of Music and Drama. There will be a new Art Gallery – one of the biggest in London. Culture in plenty.

And as for commerce, all the great City of London institutions such as the Bank of England, the Stock Exchange, the money markets, insurance companies – they're all within easy reach. And history is everywhere. The Tower of London. St. Paul's Cathedral. Guildhall. The Monument. The whole atmosphere of the City reflects a long and glorious history. But to get back to conference facilities. If you look at the captions below you'll find most of the details you need. But for fuller details, just contact our Conference Director. He'll be glad to help. With completion in 1980, we're already taking bookings for 1981 and onwards. The Barbican Centre, 11 Cromwell Tower, The Barbican, London EC2Y 8DD England. Telephone: 01-638 4141.

London's new Barbican Centre – surrounded by centuries of history, commerce and culture.



A display and exhibition area with a total of 88,000 square feet (8,100 square metres).

The Barbican Conference Hall comfortably seats 2,000 delegates.

A variety of lecture theatres, seminar and committee rooms to take anything from 5 to 275 delegates.

The Film Theatre – with all the most up-to-date audio visual equipment – seats 300 people.

The Barbican Theatre seats 1,150.

All in all, the Barbican Centre is flexible enough to house any kind of conference you wish to plan. Try it and see.

THE ROCKEFELLER FOUNDATION RESEARCH CAREER DEVELOPMENT FELLOWSHIPS IN GEOGRAPHIC MEDICINE

The Rockefeller Foundation announces the second annual competition for research career development awards of five years' duration including salary, laboratory support, and travel for investigators interested in the great neglected diseases of mankind (primarily the tropical infectious diseases). These diseases are great in terms of the vast number of individuals involved, and neglected with respect to both funding and lack of interest by the biomedical research community.

The Rockefeller Foundation has established a network of research groups in this area which at present includes departments of medicine, pharmacology, and immunology in medical schools and research institutes in the United States, Great Britain, Australia, Israel and Egypt. A critical mass of institutions now afford significant career opportunities in this field. To provide necessary career incentive, two five-year fellowships are granted annually to outstanding young investigators who have established their scientific ability by the quantity and quality of their research and by a demonstrated interest in the great neglected diseases. The deadline for receipt of grant proposals will be June 15, 1979.

For more detailed information, please write to: Kenneth S. Warren, M. D., Director, Division of Health Sciences, The Rockefeller Foundation, 1133 Avenue of the Americas, New York, N.Y. 10036.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

After geodynamics, what?

THE earth sciences depend very largely on international collaboration; so it is no surprise that there has been a succession of projects aimed at nurturing the free flow of data and ideas across national boundaries. International Polar Years, and the International Geophysical Year of 1957 led in the 1960s to the Upper Mantle Project and in the 1970s to the Geodynamics Project, which closes at the end of this year. Questions are inevitably being asked now about a possible successor to these programmes, and in Zurich last week, under the aegis of the International Union of Geological Sciences (IUGS), a wide variety of earth scientists gathered to review the state of their specialisations and to mull over a proposal for collaboration in the 1980s.

What does a low-budget international scientific programme achieve? In some respects very little. It offers no research funds Most scientists in their national context are unlikely ever to read the rationale behind projects and even less are they likely to make a major adjustment in their research to take account of the projects stated aims. And in many, though not all, countries the availability of funds for the support of research is likely to be tied much more closely to the excellence of the investigator or the relevance of the proposed work to national needs than it is to the context of an international programme Many of the remarkable discoveries in the earth sciences of the past twenty years have been made with little or no direct assistance from the prevailing project of the time. On the other hand, international projects can concentrate on two aspects of science which national systems are often not competent to assist—indeed sometimes seem positively to hinder: the bringing together of people from a wide variety of national and multi-disciplinary backgrounds, and the removal of blockages in making data easily accessible regardless of its national origin. On this basis alone the modest costs of a small secretariat, travel funds and data centres seem amply justified. Since all branches of science at all times profit greatly from this sort of assistance it is unfortunate that international unions have to convene working groups, write long reports and propose grandiose projects simply to maintain the rudiments of international and interdisciplinary scientific exchange.

Be that as it may, with the Geodynamics Project running out in ten months' time there is a pressing need for a new programme to be announced. Four years ago it seemed possible that the International Union of Geodesy and Geophysics (IUGG) might opt completely out of a further inter-union programme (the totally illogical way in which the geologists and geophysicists have separate unions and entirely different organisational machinery within them surely represents one interdisciplinary blockage which ICSU could do well to eliminate). In the past year and a half, however, IUGG has buried the hatchet and working groups convened by Dr H Illies of Hamburg (IUGS) and Dr C. Kisslinger (IUGG) have now brought forward a joint proposal for the next ten years. But even if the respective unions in their different ways accept the present document, it will not be until the summer of 1980 that final approval can be obtained from ICSU's general assembly, so there is bound to be a hiatus between one project and the next.

It is possible to identify three distinct threads of argument in discussions of this document. The first recognises that scientific advance is to a degree independent of international projects so simply reckons that the next ten years will build on what has already been learnt, though will doubtless contain some surprises—will in effect be a continuation of the International Geodynamics Project. The second believes that to be politically acceptable it will not be possible simply to say 'more of the same'—a new title will be necessary and new foci of attention will be called for. The Illies-Kissinger document carefully pulls together these two threads; the central theme of the proposed new programme would be 'the current state, dynamics, origin and evolution of the lithosphere, with special attention to the continental lithosphere'. (The lithosphere is the strong outermost shell of the Earth, of depth up to 150 kilometres beneath continents.) The programme proposes a change of focus and yet is a logical consequence of what has gone before.

The third line of thinking, however, says that earth scientists must respond to changing political climates, most notably in two areas: first, global resources, hazards and the maintenance of the environment; second, the need of the developing world for strengthened scientific and technological bases.

This geopolitical point of view has been put forward most forcefully by Professor L. Nicolaysen of the University of the Witwatersrand, Johannesburg. He recognises that the Illies-Kisslinger document does mention these matters, but would have them occupy a much more prominent position in project plans.

There are some fairly good administrative and bureaucratic reasons why this proposal can be resisted. It raises all sorts of questions that will offend countries' sensibilities, bring in new agencies, straddle difficult industry/academic frontiers, call for larger expenditure and so on Quite so. But it is time earth scientists faced up to the uneasy barriers that exist between pure and applied research, and it is time they recognised the unique role they can play in the developing world. Maybe they should look, for a start, at the success of the International Centre for Theoretical Physics at Trieste in nurturing developing world scientists, and should wonder whether the earth scientists might evolve a similar project.

It would be a mistake simply to avoid these issues as being too political or too complex. The unions, whilst accepting the present document as a sound basis on which to proceed scientifically, should grasp the opportunity they have to bring together a highly fragmented range of disciplines, to take greater steps to bring basic and applied science together and to start serious thinking about responsibilities in the developing world. □

US boosts military support of campus research

Defense Department support for basic science is returning to pre-Mansfield Amendment days. **David Dickson** reports

AFTER a gap of seven years, the US Department of Defense has re-established an office to co-ordinate its efforts in basic research and to stimulate contacts with university research groups.

This move, which was recommended in a report on the department's basic research released by the Office of Science and Technology Policy in Washington last week, reflects an effort backed by President Carter to restore military support for university research to the levels of the late 1960s. Two factors have brought this about: renewed pressure for technological innovation—with requirements ranging from laser weapons to high-speed integrated circuits—within the Department of Defense; and the continued squeeze on other sources of support for university research.

The clearest evidence of the new trend is provided in the budget request submitted by the President to Congress last month This asked for $436 million for basic research obligations in the Department of Defense in the fiscal year 1980, almost 10% of the total basic research budget If the request is accepted by Congress, this would mean an average increase for Defense Department basic research in the two Carter budgets (covering the period 1978–80) of 18.3%, considerably higher than for any other agency, and compared to an average increase of 11.4% for the National Institutes of Health, and 10.5% for the National Science Foundation

Military support for basic research reached its peak in the late 1960s, when the efforts of university scientists in fields such as nuclear weapons were supplemented by those recruited to support US efforts in Vietnam. Reaction against the conduct of the war, however, and the use of science in areas such as chemical weapons or counter-insurgency techniques, led to a wave of protests about military involvement on university campuses.

The protests became focused in an amendment made by Senator Mansfield to the Defense Department appropriations in 1970 Seen by some as merely a "good housekeeping" move, but by others as reflecting broader concerns about military involvement with science, the amendment stated that funds would only be provided to research projects bearing a "direct and apparent relationship" to a specific military function or operation

Although revised a year later to require merely a "potential relationship" —a criterion which is still in effect—the Mansfield amendment contributed to a rapid shrinkage in Defense Department support for basic science, which in real terms was almost halved between 1967 and 1975.

In its report, the OSTP panel, which was chaired by Dr J K Galt of Sandia Laboratories and included representatives of universities, industry and other government agencies, states its belief that the current level of funding has reduced the utilisation of basic research in the Department of Defense "below a minimally acceptable level". It "welcomes and applauds" recent attempts to reverse the previous decline in research funding

The panel says that such research is important to the department for three main reasons: to fill gaps in knowledge, to provide a source of new concepts, and to keep up with technological developments in other parts of the world "Growth for 10 years at a rate similar to the rate of decline of the past 10 years is indicated", it says The OSTP panel places a special emphasis on the potential contribution of university scientists in single-mindedly pursuing long-term goals rather than performing highly-specified research. The universities are a "logical" place to expec original and startling new ideas, it says

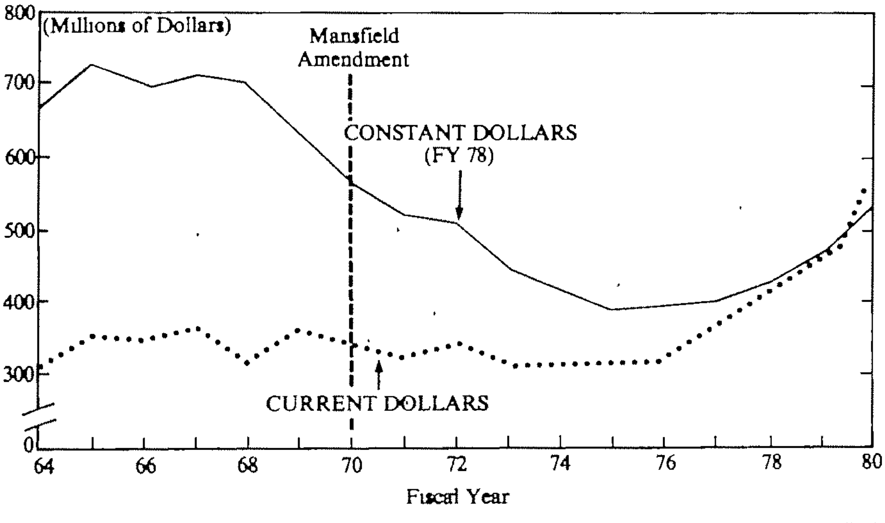
This emphasis on supporting university research is already reflected in the department's budget. Between 1976 and 1978, for example, while Defense Department support for in-house basic research was kept constant (in curren dollars), support for basic research in universities increased by almost 60%. In 1976, universities carried out 33% of the department's basic research; by 1978 the proportion had increased to 40%.

There have also been shifts in the areas of research receiving support From the US Air Force, for example there has been a decline in support for nuclear physics or atmospheric research, and an increase in materials science and engineering Mathematics however, and particularly the computer sciences continue to receive good support.

So far there has been little opposition from the academic community to the re-emerging importance of Defense Department research funds. A few re-echo the concerns of the late 1960s "The trend is part of an overall growth of military spending and militarism in this country that I consider very unhealthy for science in its broader context—it's like saying that wars are good for surgery", says Dr Charles Schwarz professor of physics at the University of California in Berkeley

And a group of scientists in Boston have recently recommended that basic research be removed from the Department of Defense budget, where they say it has a "high probability of military applicability" They have suggested that the majority of the funds be transferred to a National Technology Foundation, which would stimulate R&D in areas of technology where private industry is not yet willing to undertake the work

But most scientists are taking a more pragmatic line They point out that unlike the more applied research sponsored by the Defense Department in university-associated laboratories—suc as MIT's Lincoln Laboratory—th basic research it supports is unclassified And it also has spin-offs in other areas □



Basic research spending by the Department of Defense, 1964–1980 (Source DoD/OSTP)

DNA risks: fears calmed, but doubts remain

EXPERIMENTS carried out by research workers at the US National Institutes of Health have provided little evidence to support fears that bacteria carrying recombinant plasmids or phages containing a eukaryotic viral genome could themselves become producers of virus particles.

However, the research workers have shown that free viral DNA is capable of producing infection in mice when injected under the skin, and that infection can also be caused by recombinant phages in which the viral DNA occurs twice in succession. They have also raised the possibility, now receiving further study, that the recombinant molecules could present a hazard by transforming cells into a tumorgenic state.

These results have emerged from a series of experiments carried out at the top-level containment facilities of Fort Detrick in Maryland as part of a programme to assess the potential risks posed by the use of recombinant DNA techniques.

A team of research workers from the National Institute of Allergy and Infectious Diseases at NIH, headed by Dr Wallace P. Rowe and Dr Malcolm A. Martin, conducted two series of experiments. One involved the molecular cloning of polyoma virus in a disabled *E. coli* plasmid vector system, and the other involved studying recombinants formed between a lambda phage vector and polyoma DNA.

In the first series of experiments, the research workers found that although all the recombinants studies contained the complete, potentially infectious viral DNA, in no case did either the recombinant plasmid, or live *E. coli* containing the plasmid, cause polyoma infection in mice.

In the second series, two types of recombinant phage were found to have formed, the most common containing a single copy of the polyoma DNA, but a second type containing two copies of the DNA linked head-to-tail in tandem. The phages containing the single copies was not infectious in mice, either when given directly, or when used to infect concentrated suspensions of *E. coli* from which the DNA was extracted and administered to the mice.

However, the phages containing the tandem inserts — theoretically more likely to cause infection since polyoma genomes could be generated by intramolecular recombination—did indeed prove to be infectious in two of five mice inoculated with the phage DNA, and in two of five injected with DNA prepared from *E. coli* infected with the phage.

According to the research workers, whose findings are about to be published in *Science*, the latter result indicates that the possible cloning of head-to-tail inserts should be taken into consideration in carrying out risk assessment analysis of the cloning of DNA, although they say that such an occurrence is highly unlikely to occur, particularly in shot-gun experiments.

The research workers say that similar results on the low infectivity of cloned genomes can be predicted for other members of the *Papovaviridae* family of viruses—including the SV40 virus—as well as most other DNA viruses, containing larger and more complex genes.

However, they draw attention to a potential hazard that might be caused by the ability of bacteria containing virus DNA recombinants to induce tumours. This hypothesis is based on the ability of polyoma DNA to induce tumours in young hamsters by transforming cells; tests of any potential hazard are now being investigated. ☐

David Dickson

Science gets new champion on Capitol Hill

IT IS unusual to find a US Congressman demanding a strong, centralised state planning mechanism, a device usually associated with the nation's ideological rivals. Just such a mechanism, however, is being proposed by a member of the House of Representatives whose voice on science policy matters will be frequently heard over the next two years: Representative George Brown of California.

First elected to Congress in 1953, Mr Brown has been chosen to chair the science, research and technology subcommittee of the House science and technology committee. The subcommittee's responsibilities will be expanded by incorporating the domestic and international scientific planning committee; and the result will be to make it broadly responsible for overseeing the nation's research efforts and science policy.

Mr Brown is unashamedly partisan. "Some people talk of science as the handmaiden of society; I want to see science as a leader in our national culture", he said in an interview with *Nature* last week.

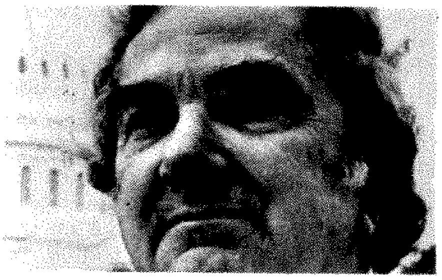
He is critical of a "laissez faire" attitude to research and development, where national concerns merely adjust the broad parameters of programmes rather than their more precise dynamics. The US, he says, lacks "a coordinated national approach to giving both direction and resources to the scientific community".

With the general pressure on research budgets, funding innovations must concentrate on the reorganisation, rather than the expansion, of resources, he says.

If this sounds a bit vague, then Mr Brown can point to his recent experience in helping steer through Congress legislation to set up co-ordinated programmes of climate and earthquake research—efforts which have earned him widespread respect in the scientific community—as well as his involvement in agricultural and environmental research issues.

But not all agree with the primacy that he would allot to science. During last year's debate on the climate programme, for example, the OSTP successfully headed off an effort to make it lead agency for the programme, a task passed to the Department of Commerce's National Oceanographic and Atmospheric Administration.

Mr Brown remains convinced that OSTP should be at the top of the pile. Although welcoming the increased funds that the science adviser has helped secure for basic science, he claims that OSTP has not confronted to the intentions and the language of the legislation which set it up in 1976.



Congressman George Brown: "I want to see science as a leader in our culture."

"We had hoped that the science adviser's office would give some coherence and strategic planning to science, and it has not done so, leaving quite a lot of unfulfilled expectations", he says.

At OSTP they see things slightly differently. "Some of these expectations were perhaps partly misplaced. We are not a kind of national clearing house on R & D", one official said last week.

Nevertheless mechanisms by which the nation's scientific efforts can be given "improved leadership" are high on Mr Brown's agenda. "The period of substantial growth experienced by science a decade ago has been extremely valuable; but it is now time to do some stocktaking". **David Dicksor**

0028–0836/79/0277—0505$01.00

France attacks UN research on Mediterranean

Mediterranean countries are to slow cooperative research on pollution, writes **Robert Walgate** from Geneva

France, assisted by Spain and Italy, has succeeded in cutting three major projects from the United Nations Environment Programme's research effort on pollution in the Mediterranean. Research has been halted on pollutants in the open waters of the Mediterranean (as opposed to the coasts), on transfer of pollutants from the air to the water, and on modelling the Mediterranean ecosystem.

Last week's meeting in Geneva of the 18 countries which signed the 1975 Barcelona convention on Mediterranean pollution was dominated by money problems, in particular shifting payment for the Mediterranean action plan from UNEP—where responsibility has lain until now—to the states themselves. France, as the largest of the 18 countries, was concerned that its contribution should be well spent, and so devoted considerable efforts to analysing the research plans of UNEP's Regional Seas director, the Yugoslav Stjepan Keckes.

Keckes had developed a 13-part programme of research in the Mediterranean known as 'Med Pol' I to XIII. The first seven deal with coastal waters, and were approved by the original Barcelona meeting. It is Med Pol VIII to XIII which were added later and deal largely with open waters that were challenged last week.

The total research costs involved were relatively small—around US $1 million a year, compared with an estimated cost of some $5 billion for treating presently untreated Mediterranean sewage effluent — so some matter of principle appeared to be at stake. If the countries were serious about dealing with Mediterranean pollution, why should they be bothered by the one part per thousand of the costs that came in the form of research?

The question mark hanging over the whole meeting was precisely what principle was at stake. According to the French delegation, the question was the quality of the research teams that UNEP had put together.

Keckes had, as a matter of principle, drawn together the expertise of existing government - sponsored laboratories around the Mediterranean coast until he had some 83 participating labs in 16 countries. These varied greatly in quality, but he took the view that governments would respect the conclusions of their own labs more than those of externally imposed teams of 'experts', however good.

Further, by receiving advice and financial support from UNEP, these laboratories could be brought up to an international standard. So far, UNEP has spent some $1.4 million on equipping these labs, mostly with American equipment (which an independent panel adjudged to be the best).

By Keckes's own admission, not all these laboratories have come up to scratch. In one southern Mediterranean state, for example, UNEP equipment languishes in a filthy laboratory without supplies of water or electricity, in spite of continued assurances that the necessary facilities will be supplied. On the other hand, neighbouring states are superior to some northern countries.

Keckes is undaunted by these setbacks, seeing the treatment of the Mediterranean and the improvement of developing country science in a very long perspective. But at Geneva the French delegation took a different view. They argued that the UNEP team could only cope effectively with local, coastal sources, and that the more complex issues of open-water pollution, air transport and ecological monitoring were beyond them. France already has programmes in these areas, said the delegation, and would make its information open to UNEP.

Keckes, however, thinks that the principle at stake may have been different—and closer to a question of the ownership of sensitive data. In the past he has found French officials "unforthcoming" about pollution of the Rhône river, which is one of the three major pollution sources of the Mediterranean (the others are the rivers Po—Italy—and Ebbro—Spain), and he suspects that the same will be true of central Mediterranean data. This data is essential to an assessment of the long-term effects of pollutants, particularly cadmium and mercury and polychlorinated hydrocarbons (from pesticides).

Further, the air—whose circulation over the Mediterranean is little understood—may be one of the main sources of these pollutants. According to Keckes "the input of airborne pollutants may turn out to be the major unknown parameter needed to assess the state of pollution in the Mediterranean basin". Measurements in the Baltic have shown that between 10% and 90% of heavy metal pollution comes from the air, and in the Adriatic it has been observed that there is some 300 times more heavy metal in the top metre of the sea than in deeper layers. Polychlorinated hydrocarbons affect the reproductive cycle of fish, and so could have a long-term effect on Mediterranean fish-stocks—a matter of more interest to southern nations with a comparatively greater reliance on fisheries, than to industrialised northern states. Nonetheless, the air-sea research programme has been cut.

The French view is that not only is the Mediterranean team of poor quality to undertake such vital work, but the necessary instrumentation and methodology is not yet available to make an accurate assessment. Keckes admits that measurements so far are only accurate to an order of magnitude, but believes that it is necessary for the whole programme to proceed in parallel, so that each part can learn from the others. He hopes that the deleted research can be revived in UNEP's long-term programme for the Mediterranean, which will be agreed in 1981.

The Regional Seas team is not discouraged. On the contrary they had been led to expect far worse. Research is only part of the Mediterranean Action Plan, which includes 'priority action' (inexplicably including development of alternative energy sources) and the 'Blue plan' for coordinated environmental management and development of Mediterranean industry. The balance between these programmes has been maintained.

In the final analysis, the budget for the Mediterranean Action Plan for 1979 and 1980 was put at $6.4 million. Of this, $3.3 million will come from the Mediterranean states and $1.6 million from UNEP. Within this the total budget for Med Pol for two years will be some $880,000. The rest will be provided by other UN agencies such as the World Health Organisation and the United Nations Development Programme for parts of the programme related to their own interests. □

Soviets soften on psychiatry?

REPORTS from Moscow suggest that, for the first time, the Soviet psychiatric establishment is willing to engage in cautious dialogue with dissidents over alleged cases of political abuse of psychiatry.

Since its foundation in January 1977, the unofficial Moscow "Working commission for investigating the use of psychiatry for political purposes" (an adjunct of the Helsinki monitoring group) has been publishing regular reports of such cases. In Bulletin 13 (November, 1978), it reported the case of Yurii Zakharovich Valov, hospitalised apparently for having made repeated protests to the media against what he saw as unfair dismissal from his job in an engineering works. The diagnosis was not revealed; however, it was known that Valov had been prescribed heavy medication—including insulin and chlorpromazine.

Dr Aleksandr Voloshanovich: asked to advise

The latest bulletin, number 14 (January 1979), takes up the case again. According to Soviet practice, Valov's case was to be reviewed by a medical commission on 7 December. As well as the regular establishment doctors, a representative of the working commission was invited to be present—Dr Aleksandr Voloshanovich, a psychiatrist, who has been acting as a consultant for the working commission since last April.

The official report on the Valov case stated that Valov was in need of "biological treatment, psychotherapy, and subsequent socio-psychiatric measures". The exact grounds for this recommendation are not entirely clear though "personality disorders" have been mentioned.

Dr Voloshanovich agreed with the need for psychotherapy and "socio-psychiatric measures" (whatever they may be), but he denied that hospitalisation and the use of neuroleptics were indicated.

This is by no means the first case where extreme psychiatric measures were employed, on political grounds, against a person suffering from a mild psychological disorder. The invitation to Dr Voloshanovich to sit in on the case may well reflect a double approach to the working commission—a desire for cautious dialogue combined with a wish to obtain at least a partial confirmation of the official verdict.

Shortage of technologists in USSR

INTEGRATION of research and industry is a fundamental tenet of Soviet science policy. It is the rationale behind the establishment of a network of 'science centres' throughout the country, and the occasional Party censure of individual research bodies which neglect the industrial problems of their local area.

In recent months, however, official emphasis has been turning away from the role of the scientists in the 'scientific-technological revolution' to that of the technologists. Last July, Mr Brezhnev told the Plenum of the Central Committee that the shortage of middle-level managers and department heads in factories was disquieting, while in agriculture only 40% of such posts are filled.

Last week, *Pravda* took up the case of other organisations including scientific research institutes, where there is also a serious lack of middle-level staff. The problem seems to be a dual one: the actual training of the required personnel and their deployment once they have qualified.

Technical college admissions, says *Pravda,* are constantly increasing (almost 1.5 million new enrolments last autumn). Nevertheless, it comments, "training has to be formulated taking into account long-range forecasts of the development of science and industry", which suggests that certain courses need re-designing and/or upgrading.

At the same time, the deployment of the present work-force of middle-level technologists—the "sergeants of industry"—is far from at its best.

The *Pravda* editorial (a traditional way of launching a new efficiency drive), calls for the relevant Party and Trade Union Committees, and the All-Union and Republic Ministries of Higher Education, to "analyse and eliminate" these defects.

British scientists help Chinese set up new university

THE UK is to help China set up and run an English-speaking technical university. The idea for such a collaboration was first raised last November when a high-level delegation from the Chinese Academy of Sciences visited the UK. British officials showing the delegation around scientific establishments were taken by surprise by the proposal, which was announced towards the end of the visit. It was not clear, according to John Deverill of the Royal Society, whether the Chinese decided to propose the cooperation on the spur of the moment or whether they had planned it before their visit.

The university is to be established at Chengtu, the capital city of Szechuan, a province of central China covering 6% of the country's land area and containing 10% of its population. Chengtu Technical College, which has 2,800 students, 1,190 academic staff, and five departments is to be expanded to include 5,000–6,000 undergraduates, 1,500 postgraduates and 13 departments and given university status. The vice-chancellor will probably be Mr Ma Shih-tu, vice-president of the Chengtu branch of the Chinese Academy of Sciences.

The key UK bodies involved in the operation will be the Royal Society and the British Council, though no one is yet sure what it all entails. "The Royal Society is not set up to start universities in other people's countries", Mr Deverill says, but he thinks it could be arranged for academics to spend some time—from one to three years—at Chengtu helping to set up new departments and start new courses. The British Council will probably help establish English courses and arrange for English teachers to spend time there. The administration and funding of the university however, are likely to be left to the Chinese. A delegation of British officials and academics now visiting China is assessing more precisely how the UK can help at Chengtu.

Chengtu will be unique as the only exclusively English-speaking university in China. The Chinese Academy of Sciences runs two other partially English-speaking universities at Hangchou and Hofei, and one partially Japanese-speaking university at Harbin. The Chinese Ministry of Education used to run French and German-speaking universities in Shanghai. There is a possibility that both these could be restarted with French and German help.

news in brief

Profit plummets after nuclear problems: Siemens, the West German transnational electrical company, has had a first quarter slowing of its sales, orders and profits because of difficulties with its subsidiary, Kraftwerk-Union, a nuclear contracting firm. Losses in KWU caused by problems in Iran, Brazil and a partial freeze on nuclear construction at home have offset an 8% increase in new orders for the rest of the Siemens group. Failure to authorise new power stations is "driving West Germany to catastrophe", said Dr Bernhard Plettner, Siemens chairman. As a way out, Siemens is trying to win a contract in Argentina to build a second nuclear plant in addition to a KWU facility in operation there since 1975. But as part of the deal, the Argentine government is demanding additional facilities to enable it to produce plutonium. The Bonn government faced severe criticism from the US for making this kind of arrangement with Brazil last year.

Swiss to vote on reactor safety: Radical new licensing measures for reactor safety to be inserted into the Swiss constitution will be voted on by the electorate on 18 February. The referendum includes: proposals for autonomous regional approval within a 30 km radius of all proposed sites; accident compensation without limits; 25-year operating concessions for both plants and the associated storage of waste; requirements that all catastrophe precautions be made public; cessation of construction or operation if at any time safety guarantees are withdrawn; and a bridging rule that will require existing plants to reapply for approval under the new rules within three years. The result of a five-year effort by a coalition of Swiss anti-nuclear groups, the campaign got boosts from a successful site occupation in 1975 at Kaiser Augsp near Basle and the emergence of a strong women's contingent opposed to nuclear power. Swiss authorities believe that if the vote goes in favour of the proposals, three plants—at Leibstadt, Kaiseraugst, and Graben, where local opposition is particularly strong—will be blocked. The bridging rule could mean that existing plants at Beznan, Muehleberg (pictured above) and the brand new 920MW plant built by the West German firm KWU at Goesgen could be closed.

Energy conservation month: October 1979 has been designated International Energy Conservation Month by the International Energy Agency (IEA). The 19 member states of the IEA are organising a variety of events to take place during October with the aim of increasing public awareness of the need for energy conservation. Several international conferences are being organised including one on the use of urban waste heat in Tokyo last October, one on energy management to be held in Birmingham, UK on 9-11 October, one on the energy conservation policies in several countries to be held in Sweden and one on the use of solar-heated water to be held in Spain.

In its national programme, the UK is laying particular emphasis on energy management, an area in which it feels it has gained some expertise in recent years. During October it will also be relaunching the "save-it" campaign for 1979-80 at a cost of £2 million and publishing the report of the Advisory Council on Energy Conservation.

Spain will promote the month by organising a 'bicycle day' and in Switzerland local authorities will be able to measure heat losses from buildings by means of aerial photographs. In general, the Mediterranean members of IEA such as Italy, Spain and Greece are hoping to demonstrate the uses and importance of solar power while some of the colder countries, for example, Denmark and Canada are laying more emphasis on conservation in buildings.

Aid to Vietnam: Vietnam's scientists, known to be desperately short of scientific equipment, are to be helped by a British charity. Medical and Scientific Aid for Vietnam has collected £8,000 to buy equipment for biologists in Vietnam. A spokesman said the money was raised in a year. Of the £8,000, £2,500 was provided by another charity, War on Want. The money has been used to buy gel electrophoresis and column chromatography equipment for work on protein separation; a spectrophotometer for routine analysis; and some general laboratory glassware. These items will help equip one of the country's newest laboratories—that of biochemistry and food chemistry in the Vietnam Scientific Research Centre in Ho Chi Minh City (formerly Saigon). The laboratory is doing agricultural research and scientists will be investigating disease resistance in rice as well as looking at cheap sources of nitrogenous fertiliser.

Bombay magnetic observatory threatened: Construction of India's largest fertiliser complex at Thal-Vaishet threatens the Colaba-Alibag magnetic observatory 5 km away. It is feared that magnetic observations taken over a continuous span of 133 years will be disrupted by electrical interference from the plant. Dr Stuart Malin of the International Geological Survey described Colaba-Alibag as "probably the most valuable magnetic observatory in Asia", but added that "the fertiliser factory is undoubtedly more important to India than the observatory". The factory has been opposed by the Save Bombay Committee, a group concerned with the pollution risk to 37,000 people 10 km downwind from the site. The committee will take the case to the Bombay High Court.

Bangladeshi centre for appropriate technology: Bangladesh is to set up a National Centre for Appropriate Technology at Bangladesh University of Engineering and Technology (BUET) that will cost $4 million and will be completed in two phases: the first in 1980 and the second in 1985.

The broad objective of the centre is to identify, develop and adapt technologies appropriate to the basic needs of the people of Bangladesh. Its studies are to be sponsored by government, autonomous bodies, private organisations and international agencies. It will provide training and research facilities and will maintain contact with similar organisations throughout the world.

Its major task will be to co-ordinate activities between scientific institutions and organisations in Bangladesh. Agriculture is the first area it will be considering. It is proposing to set up regional centres at the Agricultural University, the Academy for Rural Development, the Agricultural Institute, the Rice Research Institute and at three engineering colleges. It will monitor the diffusion of technology to the regional centres. Networks of institutions are also to be set up for industry, communications and energy with the new national centre as the focus.

The centre will also work on the design and fabrication of new products and the modification and adaptation of imported goods. Its aim is to provide government with policy alternatives on the import, adoption and adaptation of foreign technology.

Flaws in GMAG's guidelines

‘We urge that time be allowed . . . before any firm decisions about major changes in the approach to categorisation are made’ — Royal Society

• A statement issued by the Council of the Royal Society and prepared by an ad hoc group chaired by Professor W. F. Bodmer. Other members were: Sir David Evans, Professor D. C. Phillips, Dr M. G. P. Stoker, Sir Frederick Warner, and Sir Robert Williams.

WE welcome the attempt of the Genetic Manipulation Advisory Group's paper (*Nature*, 9 November, page 104) at a more rational approach to the categorisation of the experiments which come under its jurisdiction, using the framework of risk assessment. The chemical and nuclear industries have considerable experience of quantitative risk assessment, based on fault-tree analysis, and hazard and operability studies, backed by extensive data on reliability. In the longer term we believe that advantage should be taken of this experience and so we are requesting the Royal Society's recently established Risk Study Group on the Assessment and Perception of Risk, under the chairmanship of Sir Frederick Warner, to include the GMAG paper and the application of risk assessment techniques to genetic manipulation in its considerations.

Even in areas such as the chemical and nuclear industries, where extensive background data are available, there is often disagreement among experts. We believe that the present knowledge of the quantities needed for a quantitative risk assessment in the area of genetic manipulation is quite inadequate for this now to form a basis for categorisation of experiments. The absolute risk associated with any experiment involves the product of many probabilities (all, of course, less than one) some of which are known and known to be low, and so this risk may in many cases be estimated to be very low, even given our present incomplete knowledge. Categorisation of experiments, however, requires the estimation of relative risks, or ratios between probabilities which in most cases will be small, and, at the same time, quite imprecisely defined, and so we do not see how these ratios can yet be calculated with sufficient accuracy to be useful for categorisation.

Particular areas of ignorance are the probabilities of human error and the real risks associated with the ingestion of the experimental product, namely the host carrying a recombinant vector. In the case, for example, of vaccine development such as for polio, which probably involved much greater potential risks than most work with recombinant DNA, extensive data were collected on the *in vivo* effects of potential vaccines in animals and humans, on the basis of which the magnitude of the risks could be confidently assessed.

There is an urgent need for more comparable data on the recombinant DNA products and on their associated hosts and vectors, such as *E. coli* K12 and its mutants, phage lambda and other plasmid vectors. Until such data, and other relevant information required for quantitative risk assessment, are available we believe the approach suggested in the GMAG paper, and appropriate developments of it, should be used for studies of the existing categorisation, rather than for categorisation itself. If, for example, further testing fully supported the present evidence that *E. coli* K12 could not be converted into an epidemic pathogen by recombinant DNA techniques, then it might be possible to assign nearly all recombinant DNA experiments using normal *E. coli* K12 host-vector systems to category I, or at most category II.

The real risks, if any, associated with most experimental products of genetic manipulation are, as already pointed out, the most difficult to assess since they are all, so far, conjectural. While it is appropriate to encourage research in areas which might be thought relevant to the assessment of these conjectured risks, as in the GMAG paper, we believe that the discussion of such conjectured risks should be adequately documented by reference to the scientific literature and subject to comparable standards of scientific scrutiny.

The discussion in the GMAG paper falls far short of these standards. For example in describing risks (the section headed "The Conjectured Hazards") there is a progression from "conjectured" through "likely" and "potentially severe" to "possible" with no justification whatsoever. The mere existence of a list of conjectured risks introduces the notion of their probability, when some may even be impossible. In other contexts, risks of this sort have been classified, by consensus of those knowledgeable in the field, into (1) negligible, (2) possible but perhaps doubtful, and (3) definite though possibly small risks. It might be instructive to do the same with some of the conjectured risks that have been attributed to work with recombinant DNA.

The difficulty in applying the suggested new approach to categorisation is illustrated by some of the chosen examples in the GMAG paper. "Self-cloning", for example of *E. coli* K12 genes into *E. coli* K12 host-vector systems, is assigned to category I and made the subject of extensive notification and detailed reporting to GMAG, whereas the Health and Safety Executive's definition of genetic manipulation, accepted as unchanged by GMAG, specifically excludes such experiments from its remit (through the use of the phrase ". . . incorporation into a host organism *in which they do not naturally occur* . . ."—our italics).

We deplore any extension of GMAG's remit, implicit or explicit, especially into areas where there is evidence that the risks are negligible and which form a significant part of experimental work in modern biology. Any such extension should be subject to very careful further consideration and justification and should not arise automatically from the adoption of a new procedure.

It is also not at all clear why experiments involving the expression of cholera toxin genes in *E. coli* K12 need to be performed under conditions which are considerably more stringent than those required for work with *Vibrio cholera itself*. We urge that any recommendation for a higher level of containment for recombinant DNA work with a pathogen, than for work with the pathogen itself, at equivalent doses, be carefully justified. In many cases involving, for example, work with certain animal viruses it is likely, as has often been pointed out before, that recombinant DNA experiments with parts of the viral genome will entail much less risk than work with the whole virus.

We believe it to be very important that GMAG consider its procedures carefully in relation to the new US National Institutes of Health (NIH) Guidelines which came into effect on 2 January 1979. These new guidelines were prepared after extensive open, documented and subsequently published consultation with many groups in the United States and abroad, including in particular Europe and the United Kingdom, especially through the European Molecular Biology Organisation. In the earlier considerations of the

0028-0836/79/0277—0509$01.00

problems posed by genetic manipulation, following the "Ashby" (Cmnd 5880) and "Williams" (Cmnd 6600) Reports, the approach followed independently by the United Kingdom was quite close to that followed in the United States and indeed at times in the forefront.

The new NIH Guidelines, which are being adopted in some form by most other countries that are advanced in this field in Europe and elsewhere differ, however, quite significantly not only from the new GMAG proposals, but also from some of its current practice. They differ, for example, with respect to self-cloning experiments and in the use, in general, of set categories for given types of experiments, rather than accumulated case law. A set list of categorisations obviates the need, once an institution is appropriately registered, for repeated referral back to a central authority before starting any particular experiment. Now that a significant amount of case law has accumulated, we urge GMAG to consider following this approach for an increasing proportion of experiments under its remit, and so simplify its activities and those of the people it serves, while in no way jeopardising recommended standards of safety.

We believe that in cases where GMAG's procedures lead to substantial differences in categorisation from those recommended by the NIH Guidelines, the difference must be carefully justified. A lack of comparability between procedures in the United Kingdom and elsewhere, especially in the United States, could seriously jeopardise this country's research and development efforts in this important area of work and in particular, threatens our contribution to extensive international cooperation in research in this field.

In this connection we would draw attention to the coordinating activities of COGENE, the Committee on genetic experimentation set up by the International Council of Scientific Unions. It should be noted that COGENE jointly with the Royal Society is organising an important meeting in April 1979 to bring together those concerned from many countries to consider these problems.

We have emphasised the need to obtain much more quantitative data to form the basis for a quantitative risk assessment. The pooling of data on risks with the US and other countries, as is done, for example, in the nuclear industry, would greatly extend the available data base needed for a proper quantitative risk assessment.

The timing of requests for responses to the GMAG paper, just before Christmas, and its earlier working paper in the summer, has been unfortunate and the period allowed for a response very short. It is not clear why such a major change in approach should be treated with such urgency. We urge that time be allowed to collect more risk data, to assess the risk assessment approach in relation to current categorisation, and to assess the impact of the new NIH Guidelines, before any firm decisions about major changes in the approach to categorisation are made. □

Arithmetical perils

Thomas H. Jukes

RECENTLY I gave my class in elementary haematology a midterm examination that included a 'free gift' question: "A patient has an erythrocyte count of 4.57 million per cubic millimetre and a blood haemoglobin level of 14.1 gm per decilitre. What is the mean corpuscular haemoglobin content?" The answer, in picograms per erythrocyte, routinely appears on computerised read-outs of blood analyses. Most of the class refused to attempt the question. I think they felt its intricacies were so mentally disturbing that to tackle it would interfere with their answering the rest of the examination.

Arithmetical problems also arise with residues in food. The Delaney Clause of the Food Additives Amendment is interpreted as prohibiting the presence in food of any added carcinogen at any level, no matter how low. Supporters of the clause often say that there is no "noncarcinogenic" level of any carcinogen. This "no-threshold" concept is sometimes arbitrarily extended to toxicological effects other than cancer. This controverts the essential basis of the science of toxicology that the dose determines the poison. As a result, per cent, parts per million and parts per billion (ppb) merge hazily into each other in the minds of many people. I wonder how many mathematicians would willingly drink a glass of water if they were told it contained 30 ppb of arsenic? Yet the human body normally contains 40 to 300 ppb.

There was a protest about the arsenic content of California wines in one of our local magazines, with the usual charges about the malfeasance of those who would poison for profit. The authors vividly described the agonies resulting from arsenic overdosage, without mentioning the quantities involved. They also hinted darkly at a University of California cover-up of the analytical results on wine. I pointed out that the offending wines had a range of 5 to 116 ppb of arsenic and that marine fish contain 2,000 to 8,000 ppb. It was no use; the authors stuck by their smoking guns, and talked about arsenic and cancer, and the rights of consumers to be informed of "the complete known and suspected contents of all food, beverages, drugs, water and air." I hope that they stop by the health food store for some dried kelp, and ask for information on its arsenic content.

The arithmetic of selenium has stumped the finest minds in the FDA for about 20 years. It seems that they think selenium is a carcinogen. It came into initial prominence in the 1930s as a teratogen in farm animals that were fed wheat from seleniferous soils in the Dakotas. In 1957, it was found at the National Institutes of Health, and simultaneously by our group at Lederle Laboratories, that selenium was an essential nutrient, and within a few months, selenium deficiency in farm animals was reported from many parts of the world, especially in New Zealand, but also in the USA, despite the excess in the Dakotas. Mindful of the Delaney Clause, the FDA refused to permit addition of selenium, as salts, to animal feeds. Of course, they could not stop the use of fishmeal as a source of selenium. A little arithmetic would have helped: about 0.1 to 0.3 part per million of selenium in the diet is essential, Delaney or no Delaney, and 5 to 10 ppm is toxic.

The emotions aroused by arithmetical amblyopia reach a peak in disputes over fluorine. A Pittsburgh judge has just acceded to impassioned pleas that fluoridation of the local water supply be halted. The water contained 0.4 ppm of fluoride before fluoridation, and the procedure that was stopped raised this to 1.0 ppm. Apparently the added 0.6 ppm was ruled to be deadly, for some nonarithmetical reason. Incidentally, seawater contains 1.4 ppm and supports a flourishing fauna, including creatures which have splendid teeth.

correspondence

Researchers and the SRC

SIR,—We are a group of non-tenured research faculty who have been working for the University of Sussex for periods up to and exceeding ten years, during which time the university has benefited both from our skills and reputation and from the capital funds attracted by our research.

We have read with interest the recent articles in *Nature* which discussed the problems of people in our situation and would like readers to be aware of our existence as a group and of our position on the issues. We feel that the problem—while certainly a national problem—can, in fact, be solved by local action at university level: the issue is not one concerning redundancy payments, but that the university can, and should, provide permanent tenured employment for those of us who have demonstrated our proficiency and usefulness in the past.

The discussion in *Nature* has so far been concerned with researchers who derived their support from the MRC but there are many who have been supported for long periods by the Science Research Council. The SRC seems to support fundamental research in this country on the hypocritical assumption that it is the universities and their tenured staff who are carrying out the research. In fact, because of the increasing complexity of research projects and the increasing demands on the time of tenured faculty, it seems that no university group can perform any really ground-breaking research without the help of some full-time, post-doctoral research personnel. Under present conditions these research personnel are almost always non-tenured. In spite of the essential role played by these non-tenured researchers in doing the actual research the SRC maintains a policy of not supporting non-tenured research workers beyond a certain age.

In the past there was enough turnover in university and national laboratory personnel so that most non-tenured research workers eventually found a post. Also, the University Grants Committee used to provide funds to allow research projects to be "taken over" by universities but this no longer occurs. Many SRC officials, and perhaps the Council itself, still seem to feel that the universities are under an obligation to give permanent employment to research workers even though the universities claim this is impossible to do.

Even when they are in a position to make appointments the universities are not living up to their responsibilities. The majority of recent new university posts have been limited to the first few points on the lecturer's scale, thereby restricting them to people about thirty or younger. One of us was told by a professor who had just made an appointment, that he did not think any university would ever offer him a lectureship because of his seniority—referring both to his age and abilities. On a less personal level, the university here has refused to give any undertaking, in negotiations with the AUT, to show some preference to older people in temporary positions when and if new posts become available.

It is clear that in many cases the SRC is aware of the current situation. One of our members is currently supported under a research grant which contains a special condition that requires the university to employ only that particular individual as the researcher on that project, thus explicitly recognising his essential role. The SRC must however face the fact that at the moment scientific research in this country is conducted on an unconscionable basis, with untenured research personnel being treated like serfs in a feudal society, rather than the workers providing the intellectual capital which is essential to the future of a society which prides itself on its democratic traditions. The present organisation of research is basically inefficient and unstable and cannot be continued much longer: the conditions of employment of non-tenured research workers would not be tolerated in any other sector of our society

Present SRC policies include: age restrictions on appointments to SRC establishments; age restrictions on the non-tenured research personnel supported by SRC grants; attempts to force the universities to "take over" research contracts and personnel while the UGC refuses to provide the resources for such "take overs"; and restriction of the right to apply for SRC research grants to tenured members of university faculties. These are making an already difficult situation incalculably more damaging than it has to be.

There is evidently a need for basic research if Britain is to maintain any sort of competitive position in the developed world. The only way we can compete in international markets is by making maximum use of the skills and creative abilities of our people not by discarding those of us who have mastered and perfected some of the most sophisticated skills necessary for complex modern technologies.

Seismic prediction at Pozzuoli

SIR,—Tazieff (8 September 1977, page 96) makes accusations that I deliberately put about wrong data in 1970 concerning warning signs that an erruption could occur in the vicinity of the city of Pozzuoli. This is not the first time he has made this statement and I have already answered him in a technical note presented to the Pontanian Academy in 1973, a copy of which I sent to him. I can state that it is completely untrue that I was the source of bulletins or news of an impending eruption in Campi Flegrei. Indeed to the best of my knowledge no such news was spread at all.

Perhaps I may go further. Tazieff speaks of false claims of a "conspicuous temperature rise of the Solfatara's fumaroles"; but in 1970 I wrote "geothermal measurements at the Solfatara have not shown up to June 9 (the date I corrected proofs), any sensible variation in temperature". Tazieff further speaks of false claims of extremely shallow earthquakes, claiming his team disproved their existence. A paper by I. Guerra *et al.* in *Quaderni della Ricerca Scientifica* No. 82 (1972) reproduces the seismograms from these quakes and mentions a "superficiality of foci". Finally Tazieff says that the vertical ground movement or brady-seism was no faster than usually noticed over the centuries as opposed to claims that the ground had been pushed up one metre in a "very short while". Readers can judge for themselves by looking at Casertano *et al.* (*Nature* **264**, 161–164; 1976) whether the motion was average —in my reckoning it went up to 60-70 times average.

During my involvement in these matters I acted according to my moral duties without any external pressure. Only after the order to move out of tottering houses (not the city, as Tazieff declares) could I rest peacefully, and even then of course hardly with much pleasure at seeing poor people evicted. In fact eviction saved lives, maybe as many as fifty because buildings fell down in 1970 and 1972. Tazieff indeed supported a motion on 18 March 1970 which excluded the possibility of people reinhabiting old crumbling houses.

Very briefly, my involvement was this. I first reported the inversion of the Phlegrean brady-seism to the authorities on 12 February 1970, mentioning a ground upheaval of about 80 cm in little more than a year. I warned of the possibility of seismic phenomena and that even the continuation of the brady-seism might unsettle the buildings in the area At the first shock (1 March 1970) a decree evacuating tottering buildings was issued, as a precaution. 650 shocks were recorded up to 16 November 1970, six felt in Pozzuoli itself at up to IV on the Mercalli scale. Three died in November from falling masonry and rocks. In my letter of 12 February I had foreseen a seismic, not an eruptive phenomenon.

For the sake of brevity I have only refuted a part of Tazieff's gratuitous statements: it would be possible, quoting published papers to amass much more scientific criticism. Tazieff states arbitrary conclusions in order to give value to the serious charge of a supposed participation in a "construction operation". He gives no direct proof, nor does any exist, while the indirect ones he reports are wrong or deliberately altered. Therefore all of his statements are nothing but products of fancy.

Chromosomal aberrations at very low radiation dose rates

from John R. K. Savage

ONE effective way of determining whether an individual has been exposed to ionising radiation is to look for an increase in structural abnormalities in the chromosomes of their white blood cells after the cells have been induced to divide in the laboratory. The exposure to radiation produces chromosome damage which shows up at mitosis as structurally abnormal chromosomes in the resulting daughter cells. In certain cases it is even possible to calculate the dose of radiation received (Dolphin, Lloyd & Purrott *NRPB Report* R13; 1973; Dolphin, Lloyd & Purrott *Health Phys.* **25**, 7; 1973). (Chromosome-type aberrations following radiation fall into two main categories. Asymmetrical, which always result in an acentric fragment and are readily scorable with conventional staining. These are also termed 'unstable', as few cells carrying them can survive cell division. Symmetrical aberrations, on the other hand, do not result in acentric fragments and relatively few are scorable without recourse to special staining methods. Such aberrations are termed balanced because they do not pose any mechanical problem or lead to genetic loss at cell division and so the changed chromosomes can be passed on to the cell progeny (Savage *J. med. Genet.* **13**, 103; 1976)) This method has chiefly been used to detect acute radiation exposure, usually at levels above the permitted maximum, although the data are often difficult to interpret in cases of accident or environmental exposure where the ideal methodological conditions are impossible to obtain. In this issue of *Nature*, however (page 531), H. J. Evans and colleagues have shown that the technique can be successfully used to demonstrate a cumulative effect of very low doses of radiation over 10 years in nuclear-dockyard workers who have been exposed to doses well below the internationally agreed maximum permissible level of 5 rem per year.

At very low doses, or with very long exposure times, when a long period is required to accumulate a significant dose, many of the radiobiological problems (such as dose rate or dose fractionation) associated with the effects of large acute doses on aberration yield disappear Uniform exposure throughout the body also becomes less important as circulation, and the mixing of the lymphocyte pool, will tend towards greater dose uniformity in the sampled population Similarly, differences in the mode of formation of aberrations by radiation of different qualities (which shows up as the degree of curvature in the dose–response curve) are reduced, and all categories of aberration increase linearly with dose.

Cumulative doses over long periods have problems of their own however. For example, after an acute dose, there is a gradual reduction in asymmetrical (unstable) aberrations with time *in vivo*, as a result of the loss of aged cells, accompanied by an influx of 'normal' cells by division of lymphocyte precursors These 'normal' cells will of course also include the progeny of those cells with symmetrical aberrations The half-life of unstable cells in circulating blood is around 3 years (Dolphin *et al. op. cit.*), so with prolonged exposure there is a continuous loss of damaged cells at the same time as new damage is being generated

The effects of long-term exposure are complicated by the fact that the exposed subject is ageing. If there is any change in the spontaneous frequency of aberrations with increasing age (and there is evidence for this in man), or if there is any change in intrinsic radio sensitivity (very little within the age range considered here (Evans in *Chromosomes and Cancer* (ed. German) 191, Wiley, New York, 1974), the observed aberration yield may well show an increase with accumulated dose since larger doses will be received by older subjects, provided they continue at risk.

Such complications must therefore be eliminated before a positive dose effect can be established This has been done by careful statistical analysis in Evans *et al.*'s paper, and a significant effect for unstable aberrations results Aneuploidy, and chromatid-type aberrations, neither of which are likely to be the result of radiation exposure (in this experiment at least) did not show any such dependence upon dose, although both showed positive increase with age

The absence of a significant effect for symmetrical (stable) aberrations is puzzling, and cannot be entirely explained away by the difficulties of detection, since one assumes that scoring efficiency for this class is constant at each sampling time Furthermore, such aberrations are not expected to be selected against by the same mechanisms which eliminate unstable forms, so one might have anticipated accumulation at a faster rate. The application of modern banding techniques now enables these types to be scored with high efficiency, so such questions as relative selection could be solved Certainly such forms persist for up to 60 years in dermal fibroblasts (a very slow turnover cell population) following therapeutic radiation (Savage & Bigger in *Mutagen-induced Chromosome Damage in Man*, 155, University Press, Edinburgh, 1978), though some recent experiments in Syrian hamster skin (D. Couzin, unpublished) suggest that there may be a gradual elimination even of symmetrical forms with time *in vivo*.

The observed rate of aberration accumulation (which equals the dose–response curve in this case) is probably some function of the turnover rate of the cell population Experiments with chronic γ-irradiation in plants (Evans & Sparrow *op. cit.*; Sax *Science* **112**, 332; 1950; Sparrow & Evans *Brookhaven Symp. Biol.* **14**, 76; 1961) have shown that aberrations can reach an equilibrium frequency, the level of which is influenced by both dose rate and cell kinetics Possibly it is the very slow turnover of lymphocytes that allows an accumulation to be recorded

0028-0836/79/0277—0512$01.00

In which case the picture might be quite different for other tissues in these workers, particularly in those with a fast cell turnover This must be borne in mind when extrapolation is made.

It is important to note that the corrected results represent a finite 'population' trend over several years. Similar findings within an individual, sampled on successive occasions, would be almost impossible. The magnitude of a Poisson confidence interval at this sort of aberration frequency is not generally appreciated. Even the fourfold increase above background found here would not be detected without a phenomenal amount of scoring, as the authors point out.

The principal significance of the findings lies in the demonstration that effects at these very low dose rates can be found if care is exercised in the analysis to eliminate confounding factors.

The increase reported here has been established for visible unstable types which are invariably cell lethal. We may infer that similar increases probably occur in stable types and in some changes too small to be detected by conventional methods. It is these transmissible types where any genetic significance must be sought. However, their importance depends not only on the nature of the changes but where in the genome they occur and also in what cells they are found. For example, very gross chromosomal changes, orders of magnitude above those found here persist in the fibroblasts of human skin for many years following therapy without impairment of other functions or any problems for the individual. As pointed out above the rate of accumulation is likely to vary between cell systems and one will want to know what happens in other tissues, such as testis, before a real evaluation of any possible hazard can be made. ☐

Sulphide ore deposits

from J. P. N. Bedham

IT is rare that the exponents of so observational a science as geology can have the satisfaction of saying 'we told you so'; rarer still does the prediction turn out to be lucrative. The discovery of 'massive' sulphide deposits on the East Pacific sea-floor by the CYAMEX team fulfills just such a prediction. To be sure we have had the stupendous reserves of the Red Sea brines for some time, but, despite the denials of Cronan and others, there always remained the lingering doubt that in so small an ocean, so close to land and so near to major salt deposits something odd may have happened. What was needed to dispel this doubt and to satisfy the financiers of deep sea research programmes that they may be on to a winner has now been found

What were the predictions based on? It has been accepted for some time now that ophiolite complexes are the only parts of oceanic crust to have escaped destruction in subduction zones. Many of these complexes contain copper-zinc-iron sulphide ores. Indeed one—the Troodos in Cyprus—has been mined for so long that there is debate as to whether the metal gave its name to the island or *vice versa*. The Troodos ores occur in lenses (1 to 10 million tons) capped by ochres (ferruginous muds), cherts and umbers (manganiferous muds) They have long been recognised as chemical sediments. The massive sulphide lenses are underlain by disseminated mineralisation in highly altered host-rocks. These are always pillow lavas and are usually the earliest in the sequence—that is, they were formed at the axis of a spreading-centre. Their alteration was caused by a hydrous fluid at temperatures ranging up to 500 °C. Less intense hydrothermal alteration has been recognised throughout the upper 3 km of the ophiolite. Such are the field observations supporting an origin of the ores at the spreading-centre by precipitation from an exhaled fluid. However, the problems of sources of the fluid, metals and sulphur and of the mode of precipitation required an experimental approach.

Lister has shown that sea-water can interact with lava to generate an ideal potential ore-fluid. The interaction cools and hydrolyses the lava and the fluid becomes hotter, more concentrated and acidic. Such a fluid can selectively leach base-metals from rocks and transport them in solution as chloride complexes. The rate of cooling of newly generated oceanic crust requires that the predominant heat loss is by convective circulation of sea-water. Spooner and others have shown convincingly from isotopic studies that the water which altered ophiolite piles was essentially sea-water. Both Lister and Spooner, by separate approaches, have argued that the data require many rock-volumes of water to have traversed the altered strata. Models of hydrothermal systems have shown how water brought into rock by downward percolation over a wide cachement, is exhaled at the thermal centre. Corless has shown that the abundance of many elements in the oceans may in fact be controlled by hydrothermal processes and not by continental run-off as has been previously thought. These experimental data have allowed a whole new perception of the interdependence of hydrosphere and ocean crust.

Sato derived a series of elegant models to show how hot, metalliferous, acidic brines could be either more or less dense than sea-water, this depending on the balance between temperature and the amount of dissolved solids. Interaction of such brines with the effectively infinite reservoir of sea-water would result in rapid cooling and dilution. Such conditions would destabilise the chloride complexes causing the metals to precipitate. The lower density fluids would disperse, precipitating their metals over a wide zone. Such a process explains well the pronounced metal enrichments in sediments around all the mid-oceanic ridges. It could indeed account for the metal content of manganese nodules. The denser fluids would remain on the sea-floor and flow down into the nearest topographic low, there to precipitate their metals. In many cases the site of exhalation may itself be a depression and the metals would accumulate above their feeder.

Three sources for the sulphur have been proposed—the fluid itself, inorganically reduced sea-water and organically reduced sea-water. The abundance of carbonaceous sediments associated with exhalative ore deposits and the remarkable discoveries of an aphotic biota around hot-springs on the ocean-floor near the Galapagos Islands has enhanced the case for an organic reduction of sea-water. Sulphur isotope studies have usually indicated an inorganic source.

Such then was the agreement between experimental and field data that discovery of sulphides on the sea-floor was only a matter of time. Numerous examples of metalliferous sediments, of ferruginous and manganiferous crusts and indeed of active, but rather cool, springs have been reported in recent years. However the CYAMEX team have found the first sulphides. The technical problems of navigating and sampling in an oceanic rift are stupendous. The fact that the crew recognised the oddity of these rocks and sampled them is a credit to them and we can only look forward eagerly to results of their further investigations at the site.

But what exactly have they found? It would appear from their descriptions that they have, not a massive sulphide lens as such, but the deposits around

---

J. P. N. Bedham is in the Geology Department, Southampton University

0028–0836/79/0277—0513$01.00

the vents of hydrothermal springs. They have shown that sulphides can be formed directly on the sea-floor—that is, that sulphur is an integral part of the system and not a later, but necessary, additive The spires of sulphides and silica lie directly on pillow lavas and the fluids that were exhaled from these vents have deposited the bulk of their load elsewhere. Where? Were the fluids heavier than sea-water, in which case we can expect the imminent discovery of a genuine massive sulphide lens nearby; or lighter, their metals dispersed? These are the questions that must now be investigated. The chances of finding a massive sulphide lens are probably low—the system appears to have been oxidised too soon and too close to its vents, and many of its metals may never have been precipitated.

Finally, what of the economic implications? The recovery of massive sulphides from the sea-floor would seem to be economically remote with no shortages in terrestrial reserves of copper and zinc. Potentially cheap extraction of metalliferous brines offers a far better prospect. It is to this that the mining houses must turn their eyes. Is this discovery a complete fluke or could there really be a ribbon of sulphides along the ridges? Mid-oceanic ridges are generally far too exposed to the physical and chemical vagaries of the open oceans to have encouraged large scale, undisturbed, reduced environments for the common preservation of massive sulphides. Back arc basins, such as the Japan or Phillipine seas offer the same magmatic and hydrothermal processes, but in a far more protected environment. It is in these that a discovery of major sulphide deposits is more likely. □

The *recA* gene product

from B. A. Bridges

THE *recA*$^+$ gene in *Escherichia coli* is involved in many cellular functions; in particular it is absolutely required for general recombination (as distinct from site-specific or illegitimate recombination) It is also required for a number of processes which have been suggested to be 'inducible' by DNA damage. The prototype *recA*$^+$-dependent inducible process is induction of prophage λ and this is the only *recA*$^+$-dependent process for which a repressor (λ immunity repressor) is known and characterised. For others, such as Weigle reactivation, filamentation or control of DNA degradation, the existence of a repressor remains hypothetical. One thing that is clear, however, is that the *recA*$^+$ gene product is made in very large quantities following treatments (such as ultraviolet irradiation) which elicit prophage induction and other 'inducible' phenomena.

A recent breakthrough towards understanding the function of the *recA*$^+$ gene product came with the observation that a proteolytic activity capable of cleaving λ repressor was present in extracts of cells known to contain large quantities of a mutant *recA* protein specified by an allele of *recA* called *tif* (Roberts *et al. Proc. natn. Acad. Sci U.S.A.* **74**, 2283; 1977). Such cells constitutively express 'inducible' functions. Recently, the *recA* protein from *tif* cells has been further purified to chromatographic homogeneity and an ATP-dependent proteolytic activity specific for λ repressor has been shown to be associated with it (Roberts *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4714; 1978) *RecA*$^+$ protein possesses only about 20–25% of the proteolytic activity associated with the variant protein from *tif* cells.

The discovery of λ repressor inactivating activity associated with *recA*$^+$ protein has tended to focus attention on its possible role in controlling 'inducible' functions to the relative neglect of its role in genetic recombination Yet the earliest characterisation of the protein, which was only subsequently found to be the product of the *recA*$^+$ gene revealed that it bound to single-stranded DNA (Gudas & Pardee *J. molec. Biol.* **101**, 459; 1976) and there have been many observations suggesting that *recA*$^+$ protein at its normal relatively low level must interact directly with DNA during both recombination and repair, without any requirement for synthesis of large amounts such as might follow induction

Such a direct role of *recA*$^+$ protein in DNA metabolism has now been established. Following the report (Ogawa, *Cold Spring Harbor Symp. quant. Biol.* **43**, in press) that *recA*$^+$ protein hydrolyses ATP in the presence of single-stranded DNA, Weinstock, McEntee and Lehman (*Proc natn. Acad. Sci.* **76**, 126; 1979) have shown that *recA*$^+$ protein purified to near homogeneity catalyses an ATP-dependent renaturation of complementary single strands of DNA. The relative activities at different temperatures of the protein from a cold-sensitive *recA* mutant confirm that this activity is an intrinsic function of the *recA*$^+$ protein Thus *recA*$^+$ protein is a 'windase' or 'annealase' and as such can be readily envisaged to have a specific primary role both in recombination and in the repair of damaged DNA

In a parallel investigation following independent purification, Shibata, Das Gupta, Cunningham and Radding (*Proc natn. Acad. Sci U S.A.* in the press) have pursued the matter one step further and shown that the *recA*$^+$ protein can catalyse the ATP-dependent pairing of superhelical DNA and homologous single-stranded fragments to form D loops. Thus single-strand ends are aggressive and can invade homologous superhelical DNA in the presence of *recA*$^+$ protein; in its absence, such a reaction occurs only at high temperature. D loops are known to be a substrate for some endonucleases (including the *recBC* DNase). One can therefore begin to see how recombination may be initiated and the way now lies open for exploring the whole process *in vitro*.

In view of the involvement of the *recA*$^+$ gene in controlling degradation of damaged DNA and its possible involvement in allowing error-prone base insertion opposite a damaged template strand, it would also be interesting to investigate the effect of *recA*$^+$ protein *in vitro*, on say, exonuclease V activity and the 3′→5′ (proof-reading) exonuclease activity of DNA polymerase III. Three recombination-proficient alleles of the *recA*$^+$ gene, namely *tif*, *recA*$^+$ and *lexB* all yield a gene product with similar 'annealase' activity although they differ markedly in expression of inducible functions.

The data so far are consistent with *recA*$^+$ protein's being rather complex in its activities, apparently showing specific proteolytic activity, DNA-dependent ATPase activity and ATP-dependent 'annealase' activity. Moreover, it seems also to control its own induction and synthesis. Such complex activity in a simple tetramer of subunit molecular weight 40,000 is not inconceivable but neither is it common.

Because normal levels of *recA*$^+$ protein are insufficient to cause derepression of prophage λ one may well imagine that many phenomena depending on constitutive levels involve its acting as an annealase, for example normal recombination, post-replication recombinational repair, mutation in unreplicated DNA and repair of single-strand breaks produced by ionising radiation (this is not to say that raised levels of *recA*$^+$ protein might not enhance these processes). Phenomena that occur only with elevated induced levels of *recA*$^+$ protein could involve either annealase activity (for example, control of DNA degradation, multiple crossovers during Hfr x F$^-$ crosses (Lloyd *J. Bact* **134**, 929; 1978)) or re-

pressor cleavage (λ induction for example) or possibly both. In some cases (Weigle reactivation, filamentation) the mechanism is still obscure.

There is still, however, a niggling doubt about ascribing the proteolytic activity to the *recA*$^+$ protein As Roberts *et al.* state, they cannot exclude the possibility that a contaminating protease is present in their preparations even though they are chromatographically homogeneous. Consistent with this possibility is the observation that bacteria containing constitutive high levels of *recA*$^+$ protein due to the presence of the controlling mutation *spr* do not show constitutive λ induction nor do crude extracts possess high ability to inactivate λ repressor (Roberts *et al Proc natn Acad Sci. U.S.A.* **75**, 4714; 1978) Several workers have suggested that the *recA*$^+$ protein requires a cofactor to be active in prophage induction. It is not totally inconceivable that such a cofactor might be the protease and that it is present in greater amounts in *tif* mutants (although such speculation does present its own difficulties) Thus although the evidence that *recA*$^+$ protein is both a protease and a DNA annealase may be sufficient to sustain the idea as a working hypothesis, more definitive evidence must be sought and the possibility of further revelations of the functions of this remarkable protein cannot be excluded. ☐

Poles apart?

from Clive Lloyd

THERE is still much to be learned about the mitotic apparatus, especially the nature of spindle organisers. Such microtubule-organising centres (MTOCs) are believed to exist at each spindle pole, where, by nucleating the assembly of microtubules, they help construct half-spindles along which sister chromatids are guided to opposite poles. *In vitro* studies confirm that microtubules can self-assemble, but the value of MTOCs is that they localise assembly and so help control planes of division important for shaping tissues. The most familiar MTOC is associated with the centriole which is a highly structured organelle resembling a vestigial flagellum. It is noteworthy, though, that amorphous pericentriolar material would seem to be the spindle organiser in *in vitro* polymerisation studies on Chinese hamster ovary cells so, if nothing else, the centriole provides a convenient signpost for such associated material (Gould & Borisy *J Cell Biol.* **73**, 601; 1977).

Definite pole bodies are to be seen in algae and fungi, but in higher plants we are confronted with the problem that such structures are not visualised in ultrastructural studies of dividing cells. This has forced the alternative view that accumulated endoplasmic reticulum seen at the poles could, by sequestering calcium, precipitate localised formation of microtubules (Hepler in *Mechanisms & Control of Cell Division* (eds Rost & Gifford) 1977), although it is admittedly difficult to see how, in the absence of a template, the number, pattern and precise location of microtubules could be controlled.

However, a recent study on the effect of a herbicide on 3T3 fibroblasts rekindles interest in presumptive spindle organisers since the drug is well known to produce mitotic abnormalities in plants. Oliver *et al.* (*Expl Cell Res.* **116**, 229; 1978), showed that chloro-isopropyl N-phenyl carbamate (CIPC) causes the formation of multinocleate cells by inducing multipolar mitotic spindles. *In vitro* polymerisation studies indicated that CIPC, unlike colchicine, did not interfere with tubulin assembly and so it was concluded that the herbicide had affected spindle MTOCs rather than microtubules *per se* This report on animal cells echoes the earlier study of Hepler and Jackson (*J. Cell Sci.* **5**, 727; 1969) on dividing nuclei in the endosperm of the African blood lilly. Whereas colchicine caused microtubule disassembly, IPC did not, but with the latter treatment multipolar spindles were formed. However, although microtubules were seen to radiate from some central locus, electron microscopy failed to give shape to the spindle pole. Following this, Coss & Pickett-Heaps (*J. Cell Biol.* **63**, 84; 1974) used IPC to examine division in the green alga, *Oedogonium cardiacum*. They, too, found that multinucleate cells were formed, suggesting that the herbicide increased the number of MTOCs No such bodies could be identified in thin sections but with high voltage electron microscopy on thick sections the picture was quite different, for morphologically distinctive spindle pole bodies were revealed in both normal and drug-treated mitoses This family of reactions on representatives of animal cells, higher plants and algae indicates that some divisible MTOC is being affected by the herbicides but it remains to be determined whether endoplasmic reticulum, as opposed to some other associated, perhaps amorphous, nucleation site, is being perturbed in higher plant cells ☐

Clive Lloyd is in the Biosciences Division, Unilever Research, Bedford.

Chamber crystals in the stratosphere

from Brian A. Thrush

ONE aspect of stratospheric chemistry which has been largely overlooked in the recent flurry of activity has been the role of the aerosol particles These form the Junge layer in the lower stratosphere and have their peak density at an altitude of about 18 km. Although these particles, which have sizes in the range 0.05–1 μm, number only about one per cm^3, the amount of material they contain is comparable with the amounts of important trace materials in the lower stratosphere, such as the nitrogen oxides. If these species reacted efficiently with the aerosol particles, this process could be significant to the chemistry of the stratosphere. Chemical analysis shows this aerosol to contain ammonium sulphate, accompanied by persulphate and perhaps chloride, but recently Farlow *et al.* (*J geophys. Res.* **83**, 6207–11; 1978) have tentatively identified two nitrosyl sulphuric acids, $NOHSO_4$ and $NOHS_2O_7$ by electron diffraction studies of aerosol particles collected by U-2 aircraft.

The stratosphere is very dry, containing only a few parts per million of water, and it is interesting to note that $NOHSO_4$ is very stable under such conditions It is familiar to chemists as forming the 'chamber crystals' which appear in the lead chamber process for making sulphuric acid. They are formed from sulphur dioxide and nitrogen dioxide (NO_2) when insufficient water is present. The authors point out that if this compound comprised 20% of the sulphate in stratospheric aerosol then this would contain about one third of the amount of nitric oxide (NO) which is present at these altitudes Because the nitrogen oxides NO and NO_2 catalytically destroy ozone in the stratosphere, any process which affects their concentrations is potentially important In fact, neither the measured ratio of NO and NO_2 to nitric acid ($HONO_2$) nor the failure to detect pernitric acid (HO_2NO_2) in the lower stratosphere agree well with predictions based on known homogeneous chemical reactions. Reactions involving aerosol particles may be implicated here

In the stratosphere, these nitrogen compounds come mainly from nitrous oxide (N_2O) derived from denitrification processes and could therefore be

0028-0836/79/0277—0515$01.00

enhanced by increased use of nitrate fertilisers. Some nitrogen oxides are directly injected into the stratosphere from the exhausts of high-flying aircraft. For this reason it is tempting to see the formation of 'chamber crystals' as a means by which the stratosphere can simultaneously purge itself of two pollutants, but any such contribution will be confined to the lower atmosphere (the troposphere). Settling of stratospheric aerosol would not provide a significant process for removing nitrogen oxides from the stratosphere, by comparison with rain out of nitric acid. Furthermore, the increase in stratospheric aerosol in recent years is generally attributed to volcanic eruptions such as Agung in 1963 rather than to the increased burning of fossil fuels because of the efficiency with which tropospheric processes remove sulphur oxides. □

Brian A. Thrush is a Professor of Physical Chemistry in the University of Cambridge.

As an illustration of the general character of the woodcuts which so profusely adorn this volume [Cassell's Natural History, volume II] we have selected one of an interesting animal which has been a great puzzle to the systematic zoologist. "The Binturong (*Arctitis binturong*) is a curious little animal of a black colour, with a white border to its ears; it has a large head and turned-up nose; its tail is immensely long, thick and tapering, and which is very remarkable it is prehensile, like that of a new world monkey. It is quite nocturnal, solitary and arboreal in its habits. Its howl is loud. It is placed by Mr Parker among the group of the civets."
From *Nature* **19**, 13 Feb. 345; 1879.

The spiral structure of galaxies

from Bernard Jones and Scott Tremaine

ONE of the most vexing problems in theoretical astrophysics has been the explanation of the beautiful spiral patterns seen in many galaxies. It is easy enough to produce spiral structure in both galaxies and coffee cups: because they rotate differentially (the inner parts revolve faster than the outer parts), an irregular gas cloud or a dribble of cream is rapidly sheared into a spiral feature which looks very similar to a galactic spiral arm. The difficulty is that by now most galaxies have undergone 50–100 revolutions, so that any primordial spiral arms would have been wound up beyond recognition.

The most likely resolution of the winding problem for differentially rotating galaxies is that the spiral arms are not material objects, but waves of gravitational potential which propagate around the galaxy. As the interstellar gas passes through the wave it is shocked and forms bright blue stars which we see as a spiral arm; the spiral arm appears narrow because the lifetime of the stars is short compared to the time the wave needs to propagate around the galaxy. This part of the theory is comparatively well understood, but understanding the origin and persistence of the underlying wave pattern in the gravitational potential has been surprisingly difficult.

Most of the work in the past 15 years has been directed towards explaining the wave as a normal mode of the galaxy, like the oscillations of a drumhead. One difficulty with this picture is that the oscillations are damped by the very shocks that make the spiral arms visible, and the damping time for the normal mode is much less than a typical galactic lifetime. Another problem is that observations show that spiral arms are always oriented in the same sense: their convex sides face in the direction of galactic rotation. This clue tells us that galaxies are not time-reversal invariant, because time-reversal would change the direction of galactic rotation. A neutral oscillation is time-reversal invariant and a theory based on neutral oscillations therefore cannot explain this observation.

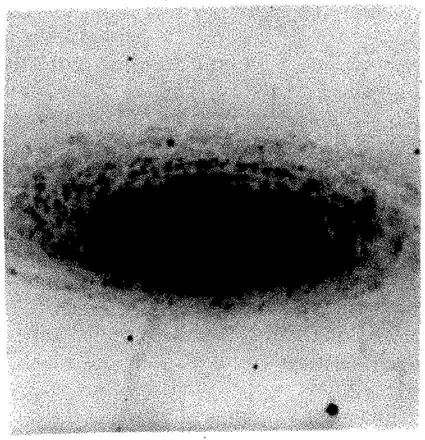
The difficulties with the simple normal mode theory for the origin of spiral structure have stimulated many important dynamical studies of galaxies. What has emerged is the realisation that differentially rotating galaxies, like the diaphragm of a drum, need to be continually excited to maintain their vibrations. A galaxy that is not excited in some way loses its grand spiral structure very quickly. Two kinds of "drumstick" have been proposed: either a satellite galaxy or a central bar-like structure such as is seen in many galaxies could provide a perturbing potential which would excite strong spiral waves.

J. Kormendy and C. Norman are the first astronomers to confront these theoretical ideas with a systematic and careful consideration of observational data; (*Astrophys. J.*, in the press). They collected pictures of all spiral galaxies whose rotation curves were known. Their sample contained 69 galaxies, of which 15 had to be discarded either because they appeared edge-on and the spiral pattern was invisible or they were too irregular to classify. Of the remaining 54 galaxies, 25 had bars and 8 had close satellite galaxies and as the theory would predict, the presence of such objects was always accompanied by well-defined large scale spiral arms.

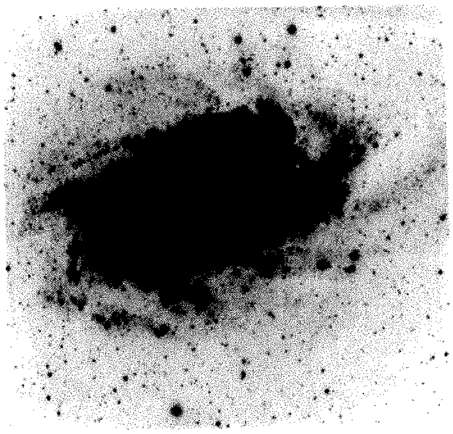
The most interesting galaxies are the remaining 21; they apparently have no known way of sustaining a spiral wave. Kormendy and Norman found that in every case, either the spiral arms were short and ill-defined, or the galaxy rotated uniformly in the region where the arms were prominent.

Retrospectively, it is easy to understand this result. In the case where the region occupied by the spiral arms rotates uniformly, there is no winding problem and the spiral structure is

NGC2841



M33



Bernard Jones is at the Institute of Astronomy, Cambridge and Scott Tremaine is at the Institute for Advanced Study, Princeton.

0028–0836/79/0277—0516$01.00

relatively easy to maintain. In a region of strong differential rotation, the vibrations are sheared into small scale spiral structure. The difficulty in spiral structure theory has always been to explain the galaxies which rotate differentially yet show well organised long spiral arms. What Kormendy and Norman have argued is that it is just these galaxies that are always accompanied by a bar or a companion

Two figures taken from their paper serve to illustrate their general conclusion. NGC 2841 is an archetype of those galaxies that have neither bar nor companion and have no coherent spiral pattern. This is to be contrasted with M33 which has neither bar nor companion, yet has a clearly identifiable spiral design contained within the region of the galaxy where there is almost solid-body rotation The region of solid-body rotation in NGC 2841 is much smaller in relation to the size of the visible disk. What we may be seeing now is the emergence of a galaxy classification scheme that can be tied directly to galactic dynamics. ☐

T-cell regulation

from Rod Langman

DISCUSSIONS at the most recent Armand Hammer Workshop* centred on suppression and suppressor factors elaborated by T lymphocytes, Ir-gene effects and H-2 restriction, and on the question of idiotypic determinants on T-cell factors and T-cell receptors An impressive array of data was closely scrutinised; however, there was little discussion of how this data could be interpreted in terms of the current theories of immunology. The calm of hindsight has revealed some concepts and details that must be settled before we are in a position to manipulate the immune system rationally.

The network concept of an immune system has captured the imagination of many immunologists, and while associative recognition theories of immune regulation are less popular, they seem to fit many of the facts better. What, then, are the critical differences between these two viewpoints? First, the network demands a system of cell–cell activation and inhibition interactions that are balanced, and which exist independent of antigen. Associative recognition theories require cell-cell interactions to occur only by way of antigen bridges which signal activation, leaving suppression with a modulating role during antigen-induced activation Second, the network demands that suppression be paramount in the discrimination between self and non-self (which leads to unresponsiveness towards self antigens) while in the associative antigen recognition theories, unresponsiveness to self is a case of T-cell deletion that involves mechanisms other than suppression.

With these distinctions drawn between the two conceptual approaches to immunology, what experiments are most likely to resolve the differences? On the question of self-tolerance the radiation chimaeras will probably prove the most informative. For example, consider a mouse of strain A which has been thymectomised, irradiated, restored with fetal liver (AT × FL, for short) and grafted with an $(A \times B)F_1$ thymus. When this mouse is immunologically mature, say 8–12 weeks post restoration, removal of the F_1 thymus graft will (1) remove the tolerated B antigen, and (2) prohibit any further T-cell maturation If the suppressionists and network theorists are right then reactivity to B should be readily recovered; whereas, if the opposition is correct, reactivity to B will not be recoverable.

Another aspect of the self and non-self distinction deals with the phenomenon of H-2 restriction. Reduced to its simplest components in the cytotoxic T lymphocytes (CTL), overall specificity of effector cells is determined by two different antigen sets; one encoded within H-2K or H-2D (restriction antigens), the other encoded elsewhere, either by viruses or other genes such as H-Y (X antigens). The restriction (R) antigens are essentially within the 'self'-domain, whereas the X antigens are within the 'non-self'-domain There was some discussion as to whether CTL recognised R and X antigens separately or only a new antigenic determinant (NAD) formed by the complexing of R and X antigens. However, M. Cohn (Salk Institute) argued that restriction specificities (that is, anti-K/D) are selected in the absence of X (that is, non-self) antigens (as shown by Bevan and Zinkernagel's early chimaera experiments) and therefore NAD's cannot be the only class of antigens recognisable by CTL. Thus, it seems difficult to avoid having two antigen recognition sites on the T cell, one for self (anti-R), the other for non-self (anti-X), and from this it follows that each site must carry different idiotypic determinants. However, if each CTL carries two different idiotypic determinants, then each CTL will have conflicting inputs from within the idiotype-regulated network. In short, the best available interpretation of H-2 restriction is simply incompatible with network theories. As a consequence, believers in the network insist that H-2 restriction must be a complicated form of suppression; but nobody has proposed a mechanism.

Despite the demise of the network there remains a body of data showing that idiotypic recognition can be involved in the regulation of immune responses. Within the framework of associative recognition, idiotypic recognition, and even idiotypic specific regulation, can certainly occur, but it must be a second-order phenomenon, not primary as the network theorists believe.

Restrictive recognition can be readily incorporated into associative antigen recognition theories, but this opens the question as to the origin of the receptors for restricting and X antigens. There is a growing body of evidence that receptors on some classes of T cell have idiotypic specificities which parallel those found on B-cell derived immunoglobulins, and these idiotypes are apparently controlled by genes mapping in V_H. Oddly enough, the immunoglobulin V_H controlled idiotypes usually require V_L for expression of the idiotype, while in T cells there is no evidence for an L chain related to the Ig set (that is, κ or λ). The receptors bearing NP-idiotype isolated from T cells (K. Rajewsky, Köln), and the ARS and GAT-idiotypes found on T-suppressor factor (B. Benacerraf, Harvard University) have been serologically and chemically analysed and provide strong evidence that at least some T cells have receptors which carry idiotypes controlled by V_H genes. It is important to question the significance of these findings in terms of the role of these idiotype-bearing T cells in regulating normal immune responses One is left to ponder quietly the fact that it is only anti-idiotypic antisera that put V_H-determined idiotypes on T cells This is especially worrisome in light of the known mutations which affect T-cell responses in an antigen-specific way; without exception, they are not V_H linked. Are the anti-idiotypic antisera leading us down the right or wrong pathway? Perhaps it is too soon to judge, but on purely theoretical and aesthetic grounds the T-cell receptor is unlikely to be encoded in the V_H locus; the H-2I(JEC) region offers intriguing possibilities.

The phenomenon of Ir genes, particularly those mapping to the H-2IA and H-2I(JEC) regions which show complementation, has continued to fascinate. If there is any consensus among Ir-gene speculators, the macrophage or antigen presentation system seems the most likely site of Ir-gene action. Perhaps the best support for the macrophage–Ir relationship came from experiments based on an antigen-

---

*An Armand Hammer Workshop on the problems of T-cell regulatory mechanisms was held at The Salk Institute, San Diego on 26–30 November, 1978

Rod Langman is at the Salk Institute, San Diego driven, macrophage and T-cell dependent, proliferative assay (PETLS), which showed that a mixture of two complementing non-responder macrophages were able to complement in the stimulation of F_1 T cells while of course the F_1 macrophage did stimulate (W. Paul, National Institutes of Health, Bethesda). This problem might be clarified by the use of two chimaeras. For example, if A and B are two complementing non-responders, the following two chimaeras would test complementation effects: (1) an (A × B)F_1 is grafted with A and B thymuses separately so that F_1 macrophages present antigen to a mixture of A and B restricted cells; and (2) an (A × B)F_1 mouse is irradiated and reconstituted with a 50:50 mixture of A + B cells which will then differentiate in an F_1 thymic epithelial environment so that each cell, T and macrophage, is genetically either A or B but is restricted to F_1 antigens. The results from these two chimaeras will distinguish between intracellular complementation and intercellular complementation.

Some Ir-1 gene phenomena are closely tied to restricting antigens, H-2K, IA and D, while others are linked to the H-2I(JEC) region which is not known to code for any restricting antigens. Although from the known genetics and structure of immunoglobulins it is expected that V_H and V_L should complement in generating unique antigen-binding specificities, it is rarely suggested that Ir-A and Ir-(JEC) gene complementation signify interactions of V_L–V_H type. However, a combination of serology and chemistry has shown that there are molecular, and possibly antigenic, complexes formed between gene products from the I-A and I-(JEC) regions (Uhr, Southwestern University; H. O McDevitt, Stanford University). Another intriguing possibility is that I(JEC) encodes the V region of the T-cell receptor. Thus, after 15 years, we still seem to be grasping for a conceptual framework that converts the phenomena of Ir genes into commonsense understanding. In fact, this is a fair comment on T-cell regulation in general. ☐

Confining current in tokamaks

from J. G. Cordey

THE poloidal magnetic field in a tokamak fusion reactor, which is essential for plasma confinement, is sustained by a toroidal current In the present experiments this current is driven by an electric field which is produced inductively by arranging for the toroidal plasma to be the secondary of a transformer. This technique of generating the toroidal current is inherently pulsed and since it seems that for a reactor to be economic it will have to be run in a steady state mode, some alternative steady state method of generating the current will have to be found.

The first such scheme was put forward by Ohkawa (*Nucl. Fusion* **10**, 185; 1970), his suggestion was to inject a separate species of fast ions in the direction parallel to the field line so that these ions circulate around the torus and form a toroidal current. The strength of the current is proportional to the number of transits the fast ions make around the torus before becoming thermalised This number is referred to as the stacking factor S and equals $\tau_s V_f/2\pi R$ where τ_s is the fast ion slowing down time, V_f is the mean velocity of the fast ions, R is the major radius of the torus Thus the total fast ion current is I_0S where I_0 is the injection current

The electrons gain momentum from the fast ions through Coulomb collisions, so they also have a net drift velocity in the same direction as the fast ions and hence tend to reduce the total current. The expression for the net current which is obtained by balancing the forces acting on the electrons may be put in the form $J=I_0S(1-Z_f/Z_{eff})$ where S is the stacking factor, Z_f the charge number of the fast ions, and Z_{eff} the effective charge number of the plasma. Thus it would appear at first sight that unless the plasma charge and fast ion charge numbers are different there would be no net current. However, if the effects of the trapping of electrons in the toroidal field gradient and the non-Maxwellian nature of the electron distribution are taken into account, there is a net current, even when $Z_f=Z_{eff}$.

The first measurement of this beam-induced current was made on the Culham Levitron (Start *et al Phys. Rev. Lett.* **40**, 1497; 1978) In this experiment a modulated beam of fast protons was injected into the device and the net circulating current was obtained from the voltage induced in a pickup coil which looped the plasma. The current was measured as a function of electron temperature and found to differ significantly from the predictions of the simple theory The discrepancy was due to the inadequacy of the theoretical model and a kinetic treatment (Cordey *et al. Culham report CLM—P547*; 1978) which took into account the non-Maxwellian nature of the electron distribution and electron-electron collisions was found to give much closer agreement. The implications of the new theory for tokamaks are fairly minor since the correction term is of the order $\bar{v}_f^2/v_e^2$ (where v_e is the thermal velocity of the electrons), which is usually small in tokamaks. The full expression for the beam-induced current in a tokamak including trapped electron effects (Connor & Cordey *Nucl. Fusion* **14**, 185; 1975) and the above correction

$$J=I_0\,S\left\{1-Z_f/Z_{eff}+1.46\,\varepsilon^{\frac{1}{2}}\frac{Z_f}{Z_{eff}}\;A(Z_{eff})-1.2\,\frac{\bar{v}_f}{v_e}^{2}\right\}$$

where $A(Z_{eff})=1.68$ for $Z_{eff}=1$; 1.18 for $Z_{eff}=4$ and 1 for $Z_{eff}=\infty$. There has been no clear identification of this current in a tokamak yet. However, sufficiently high neutral injection power is now available on several experiments and so one expects an observation of this current in the near future.

Another method of generating the toroidal current has recently been proposed by Fisch (*Phys. Rev Lett.* **41**, 873; 1978) In this scheme a small group of high energy electrons are accelerated in a direction parallel to the field lines by high phase velocity r.f. waves. The frequency of the waves is near the lower hybrid frequency and they are launched from an "end fire waveguide" array, which directs the power flow parallel to the field lines. The waves transfer their momentum to the electrons through resonant particle damping and this drives a current in the plasma.

The power required to drive the current is calculated from the power dissipated by the group of resonant electrons through collisional drag on the remainder of the plasma An effective r.f. resistivity η_{rf} is then defined and this may be compared with the ohmic resistivity η_{ohmic} of the plasma. For equal currents the ratio of $\eta_{rf}/\eta_{ohmic}=10\,v_e^3/v_1^2\,v_D$ where v_D is the drift velocity of the electrons in the ohmic case and v_1 is the velocity of the resonant electrons in the r.f. case. Thus for low current levels (v_D small) the r.f. current dissipates more power than the ohmic current. At higher current levels, provided $v_1 \gg v_e$ the r.f. current begins to dissipate less power than the ohmic current.

J. G. Cordey is at the Culham Laboratory of the Euratom/UKAEA Fusion Association, Abingdon

0028-0836/79/0277—0518$01.00

Calculations are given for reactor parameters, and it is found that the power required to drive the current is approximately 3% of the total fusion power output and that only 1% of the area of the wall would be required for the wave guides.

Clearly an experimental demonstration of both the fast ion and r.f. schemes in a tokamak is required before any realistic assessment of the reactor potential of either of these schemes can be made. ☐

Masses of exotic nuclei

from John Edgington

THE stable nuclei occupy a narrow strip on a plot of proton number Z versus neutron number N. Increase Z or N by a few units, and the resulting nuclei undergo β-decay, increase Z or N greatly and even this limited stability disappears, the excess nucleons being ejected singly or in clusters

This fragility of all but a limited number of nuclei has to be explained, eventually, in terms of the individual nucleon-nucleon interactions. Given the complexity of many-body calculations, it is hardly surprising that for practical purposes, such as estimating nuclear binding energies and masses, simpler prescriptions are used. These 'semi-empirical' formulae are based on the liquid-drop model but include the main features of the individual interactions in an approximate way. The values of the numerical coefficients involved are adjusted to fit the masses of stable nuclei, and the most widely used of these formulae, the Garvey-Kelson relation (Garvey *et al.*, *Rev. Mod. Phys.* **41**, Sl; 1969) also considers correlations between nuclei with closely similar values of Z and N.

The most stringent tests of these formulae occur, of course, for nuclei far from the narrow stability strip. Since these are very short-lived, some subtle experimental techniques are needed. A fine example is that reported from the LAMPF accelerator, Los Alamos, by a LASL/Northwestern University group (Seth *et al.*, *Phys. Rev. Lett.* **41**, 1589; 1978) who have measured the mass of ^{18}C This exotic nuclide, with twice as many neutrons as protons is one of a class of nuclei having N = Z + 6 which seem to mark a significant boundary on the stability map of light nuclei. If N and Z are both odd, these nuclei are unstable to particle emission; if even, they appear to be stable. Like other neutron-rich nuclei, ^{18}C can be produced fairly readily in heavy ion collisions, or as a spallation product of heavy nuclei, but these violent processes are quite unsuited to precise mass measurements.

Seth and his colleagues have produced ^{18}C by the double charge exchange (DCX) reaction $^{18}O(\pi^-,\pi^+)^{18}C$, using the energetic pion spectrometer at LAMPF and measuring the energy of both the incident π^- and the outgoing π^+, to obtain the binding energy of ^{18}C by subtraction The technical difficulties are great. There is a huge background of electrons from π° production and decay, but these are entirely eliminated by time-of-flight and Cerenkov counter techniques; also, the spectrometer's energy resolution is too poor for mass measurements, so a calibration reaction involving nuclei with known masses, $^{12}C(\pi^-,\pi^+)^{12}Be$, was also measured. The group had previously confirmed (LA-7457-PR Progress Report, Sept. 1978) that their equipment had the desired sensitivity, using the simpler reaction $^{9}Be(\pi^+,\pi^-)^{9}C$, since a target of natural beryllium metal poses fewer difficulties than the enriched ice target used for the ^{18}O DCX reaction.

Seth *et al* compared their result for the mass excess of ^{18}C, 24.91 ± 0.15 MeV, with the Garvey-Kelson relation. Earlier predictions had suggested a somewhat lower binding energy, but a recalculation of the G–K prediction, using recent measurements of the ^{17}C and ^{18}N, yielded a mass excess of 25.04 ± 0.10 MeV, in excellent agreement.

It is worth stressing that Seth *et al 's* measurement would not have been thought possible, even with technical ingenuity, two years ago when the cross sections for the DCX reactions (π^-,π^+) were thought to be exceedingly small. Conventional wisdom had it that reactions connecting analogue nuclear states were much more likely than those between non-analogue states. Roughly, analogue states are corresponding states in different nuclei which differ only in that one or more protons and neutrons have been interchanged, but no rearrangement of the nucleon orbitals has occurred. According to this opinion, any necessary orbital rearrangement would depress the cross section greatly. In 1977 another group working at LAMPF, B. M Preedom's LASL/University of South Carolina/ANL collaboration, showed that the reaction $^{18}O(\pi^+,\pi^-)^{18}Ne$, connecting analogue states in the two nuclei, had a cross section only about twice as large as that of $^{18}O(\pi^+,\pi-)^{18}Ne$. The latter converts neutrons in a filled shell to protons occupying the next higher orbital, and so connects non-analogue states. Now, whereas it is always possible to find nuclei with excess neutrons on which the (π^+,π^-) reaction can connect analogue states with no orbital rearrangement, there are no stable nuclei (other than ^{1}H and ^{3}He) with excess protons; and so (π^-,π^+) reactions necessarily connect non-analogue states.

The results of Preedom's group (*Phys. Rev. Lett* **38**, 149; 1977; *Phys. Lett* **69A**, 55; 1977) greatly encouraged study of (π^-,π^+) reactions, since there is now seen to be no reason to suppose that their cross sections are unusally small. Even so, Seth *et al.* observed only about twenty events leading to the ground state of ^{18}C. They now plan to measure the mass of several more extremely neutron-rich nuclei, including ^{48}Ar which has Z = 18, N = 30; this will be reached by the reaction $^{48}Ca(\pi^-,\pi^+)^{48}Ar$. We may expect other such measurements in the near future, especially as the re-evaluated Garvey-Kelson relation now predicts greater stability against particle emission than before. ☐

The current state of eukaryotic messenger RNA

from H R. V. Arnstein

THE isolation of different messenger RNAs and their translation into specific proteins in a number of cell-free systems are now almost routine. Moreover, the nucleotide sequences of several messengers have been established Given that the concept of mRNA emerged less than 20 years ago impressive progress has been made

At a recent EMBO Workshop* the main topics were heterogeneous nuclear RNA (hnRNA) processing, hnRNA–protein complexes, free cytoplasmic messenger ribonucleoproteins (mRNPs), the cytoskeleton in relation to protein biosynthesis, polysomal mRNA–protein complexes and translational control

The general picture which emerged was that the molecular aspects of transcription and the subsequent processing of the primary transcripts are known in outline, but there is still considerable scope for detailed studies of the enzymes involved and of the control of mRNA synthesis in eukaryotes Moreover almost nothing is known about the transport of processed mRNA from the nucleus into the cytoplasm and there is uncertainty about the proteins which occur in association with mRNA precursors in the nucleus and with free and polysomal mRNA in the cytoplasm. These mRNA–protein complexes are a characteristic feature of eukaryotic cells, but their functional significance is obscure

---

*Held at Hapert, The Netherlands on 27 November–1 December, 1978 The meeting was organised by H Bloemendal and W J. van Venrooij of the Biochemistry Department, University of Nijmegen

As discussed by J. E. Darnell (Rockefeller University) for adenovirus mRNA, capping of transcripts takes place very early, perhaps at the beginning of transcription RNA polymerase reads past the site at which poly(A) is subsequently added and the primary transcript is cleaved endonucleolytically before addition of the 200-residue poly(A) tail. Methylation then takes place, followed by splicing to give the final processed transcript. The size of the primary transcripts of eukaryotic genes remains somewhat controversial with K. Scherrer (Cancer Institute, Lausanne) still favouring very large products. This question will ultimately be settled by comparisons of nucleotide sequences of genomic DNA, primary transcripts and processed messengers The use of restriction endonucleases and DNA cloning has led to rapid progress as illustrated by the discussions of globin gene expression (R. Flavell, University of Amsterdam), the structure of late SV40 mRNAs (W. Fiers, University of Ghent), post-transcriptional processing of the yeast tyrosine tRNA, which contains a 14 nucleotide intron (J. S. Beckmann, Beth-Dagan, Israel), and mouse pre-mRNA structure (A. P. Ryskov, Inst. Molecular Biology, Moscow).

The complexity of heterogeneous nuclear RNA was illustrated by the isolation from nuclei of both 30–50S monomers and heterogeneous polymers, which differ in protein composition and resistance to ribonuclease digestion (M. Jacob). In some cells, the 30S nuclear RNP contains multiple copies of four major structural polypeptides (molecular weight 34,000–40,000) held together by protein-protein interactions (T E. Martin, University of Chicago), whereas in others as many as 87 different proteins have been identified, including some 20 with molecular weights of 30,000–40,000 (Scherrer) In addition to hnRNA, nuclear RNP particles contain also a low molecular weight RNA (snRNA) which has a longer half-life and appears to be hydrogen-bonded to hnRNA by sequences of some 15–25 nucleotides (A. Alonso, Cancer Centre, Heidelberg).

Free and polysomal messenger ribonucleoproteins present in a wide range of different cells were much discussed. No definite conclusion emerged concerning relationships between any particular protein(s) and the functional state of the messenger, but there is increasing evidence for the view that mRNP proteins may be turning over independently of the mRNA. Thus, proteins associated with free mRNP from muscle cells were reported to be displaced during translation of the messenger in reticulocyte lysates (S. Sarkar, Boston Med. Res. Inst.). The widespread occurrence of RNA-binding proteins in eukaryotic cells (L. P. Ovchinnikov, Molecular Biology, Moscow), as well as the observation that free globin mRNA becomes associated with proteins during translation in a cell-free system from Ehrlich ascites tumour cells (H R V Arnstein, King's College, London), all lend support to the idea of a dynamic state of mRNP proteins despite the well-known strong chemical interaction between the proteins and mRNA

Differences in mRNP proteins of membrane-bound and free polysomes (N. Standart, Univ. College, Cardiff) and also after virus infection of cells (J G Tasseron-de Jong, University of Leiden) suggest possible functions of proteins in relation to the intracellular location of messengers and control of translation Two other specific proteins, ribophorin I and II, which are present in the rough endoplasmic reticulum of rat liver and other secretory tissues are also involved in binding ribosomes to the membrane (D. A. Sabatini, New York University Medical Center).

Several contributions dealt with the cytoskeleton and its significance for protein synthesis. Thus, polysomal mRNA may be linked to the cytoskeleton by the poly(A) tail and poliovirus mRNA displaces cellular mRNA from intermediate filaments, which may explain the cytopathic effect of poliovirus and other viral infections (S. Penman, Massachusetts Institute of Technology). In lens tissue a particular membrane protein is synthesised by polyribosomes which are specifically bound to the action of the cytoskeletal framework (H. Bloemendal, University of Nijmegen). It was also suggested (A. O. Pogo, N Y. Blood Center) that in interphase hnRNA is bound to a highly ordered structure formed by non-histone protein interactions and that after post-transcriptional processing mRNA leaves the nucleus already attached to the cytoskeleton. Thus, both processing and transport of mRNA may be dependent on the internal structural organisation of the cell.

In the session on translational control, differences in the distribution of mRNA between the polysomal and non-polysomal cytoplasmic fraction were reported in Friend erythroleukaemic cells before and after induction of globin synthesis with dimethylsulphoxide (F. Gabrielli, University of Pisa) and in mouse ascites cells (Martin). Also, during the development of the dormant gastrulae of *Artemia salina* changes seem to occur in both the translational efficiency and sequence complexity of mRNA (T C. James, NIMR, London). Dormant gastrulae contain a unique 19S protein complex, which is an aggregate of 40–50 molecules of a 24,000 molecular weight protein with similar properties to the *Artemia* elongation factor–1$_H$ (M Kondo, University of Antwerp). On resumption of development this complex decreases, suggesting the existence of translational control involving elongation either in addition to or instead of the more usual regulation of initiation. Finally, the apparently endless complexities of translational control were illustrated by the discovery of an 11S cytoplasmic protein which prevents the inhibition of protein synthesis by the haemin-controlled repressor (H. O Voorma, University of Utrecht). This factor is also able to reactivate reticulocyte lysates after preincubation in the absence of haemin, has no eIF$_2$ activity and probably functions by restoring the activity of the endogenous initiation factor. □

A hundred years ago

CAPTAIN COOK

IT seems on first thoughts rather a strange proceeding to publicly celebrate the centenary of the death of a great man, especially when that death was a murder. But this is what the Paris Geographical Society have arranged to do tomorrow in the case, not of any of their own explorers or navigators, but in the case of England's greatest exploring navigator, Captain James Cook, who was murdered 100 years ago tomorrow by the natives of the Sandwich Islands. Cook, and with him England, owed some gratitude to the French, whose government of the time, though at war with this country, generously gave instructions to their warships and colonial governors, not only not to molest Cook in his pursuit of knowledge, but to render him all reasonable assistance. To him we owe the discovery of the Sandwich, and many other Pacific Islands . . and proved that [Australia] was unconnected with New Guinea, and above all, dispelled the long-lived illusion of a great southern continent, having been the first to cross the Antarctic Circle.

Thermal–timing instability in neutron stars

George Greenstein

Department of Astronomy, Amherst College, Amherst, Massachusetts 01002

A thermal instability can occur in neutron stars, in which a significant burst of heat is generated in a short period of time. Accompanying this heat pulse is a change in the pulse repitition rate of the pulsar. A perturbation analysis of a simple model shows that the instability becomes easier to trigger as the star's initial temperature is reduced, and that once started it can grow very rapidly. The resulting time evolution of the pulsar angular velocity may resemble a period jump.

IT has been known for some time that, if neutron star interiors are superfluid, heat will be frictionally dissipated within them as their rotation slows. It is shown here that in certain circumstances this process can become unstable: that the frictional generation of heat can undergo a runaway, depositing a significant burst of heat in the star in a short period of time.

This runaway is purely thermal in nature: it results from an instability in an energy-generation process. Nevertheless, it has observable effects on the rotation rate of the pulsar. Neutron star interiors rotate more rapidly than their surfaces, and the frictional coupling between the two increases with increasing temperature. A burst of heat therefore tends to cause the star to 'seize' up: the inside slows down, and the outside—the pulsar—speeds up. The thermal instability manifests itself through its pulsar timing effects.

The obvious question is whether such a process has anything to do either with the well-known period jumps that have been observed in the Crab and Vela pulsars, or with the restless behaviour which apparently occurs in all pulsars. This possibility is considered later. However, a less obvious but equally important question, and one that is not considered here is: if the steady-state rotation of a neutron star can become unstable, what is the rotational state of such a star?

The instability in words

Baym *et al.*[1] state that a neutron star consists of a superfluid component and a charged-particle component; the pulsar clock is determined by the rotatiom of the charges (see ref. 2 for a more detailed review). The two components are coupled together by a frictional force density **F**:

$$\mathbf{F} = \rho_s \rho_c \mathbf{v}/\rho\tau \tag{1}$$

where ρ_s is the mass density of the superfluid component, ρ_c that of the charged component, $\rho = \rho_s + \rho_c$ is the total density, **v** the relative velocity difference between the two components and τ the relaxation time describing interactions between the two. The force (**F**) slows the rotation of the superfluid. In the steady state the relative velocity difference **v** adjusts itself until **F** is sufficient to slow the superfluid at the same rate as the charges. This slowing down, because it is caused by friction, generates heat at a rate $\mathbf{F}\cdot\mathbf{v}$ erg cm^{-3} s^{-1} throughout the superfluid.

The star also loses thermal energy through radiation (of photons from its surface, for instance). If C is the specific heat of the star as a whole the equation for its temperature T will have the form

$$C\dot{T} = \int \mathbf{F}\cdot\mathbf{v}\, \mathrm{d}^3r - \{\text{cooling rate}\} \tag{2}$$

Of the quantities entering into the first term on the right-hand side of equation (2) only the relaxation time τ depends on the temperature: τ decreases as T increases (see equation (5)). Therefore, this heating term is an increasing function of T. The same is true of the cooling term. There are only two possibilities: either the heating term increases with temperature faster than the cooling term, or it does not. These two cases are sketched in Fig. 1.

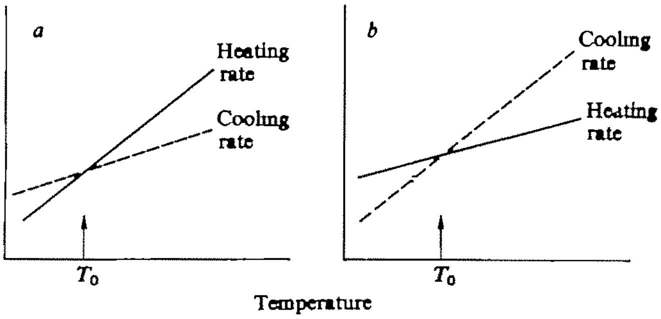

Fig. 1 The dependence on temperature of the heating term (solid lines) and cooling term (dashed lines) of equation (2). The time rate of change of the temperature is determined by their difference. T_0 denotes the steady-state temperature. *a*, Unstable; *b*, stable.

Figure 1 determines the time rate of change of T using the difference between the heating and cooling terms. A time-independent temperature, T_0, is obtained if they are set equal. This is the steady-state frictionally generated temperature of the star.

Is this equilibrium configuration stable? If we prepare a star with temperature, T_0, and then perturb the temperature slightly, then Fig. 1 shows that in (*a*) the perturbation increases in time, while in (*b*) it dies out. Case (*a*) is thermally unstable, both against sudden heatings and sudden coolings. Case (*b*) is stable. A star will be thermally unstable if its energy-generation mechanism is more sensitive to the temperature than is its cooling mechanism.

It is not known whether vortex lines pin to nuclei in neutron star crusts. If they do, a turbulent boundary layer may result, in which the processes described above should take place. However, no quantitative theory of this layer is available.

0028-0836/79/0277—0521$01 00

Perturbation theory on a simple model

Most of the essential features of the instability can be obtained quite easily from the simple two-component model introduced by Baym *et al.*[1] in which the superfluid is supposed to be rotating rigidly. The known pulsars are cold enough for the dominant mode of cooling to be photon emission from the surface. Confining our attention to this case, and combining equations (1) and (2) we obtain after an obvious transformation:

$$C\dot{T} = \frac{I_s I_c}{I\tau}[\omega - \Omega]^2 - 4\pi R^2 \sigma T_e^4 \tag{3}$$

where I_s is the moment of inertia of the superfluid, I_c that of the star, $I = I_s + I_c$, ω is the superfluid angular surface velocity and Ω that of the charges, and T_e is the surface temperature of the star. Here we will take T_e to be proportional to T and neglect the temperature dependence of the specific heat: these assumptions are for convenience only and do not affect the qualitative features of the instability. Equation (3) is then of the form

$$\dot{T} = a/\tau(T) - bT^4 \tag{4}$$

with the factors a and b independent of temperature. (In a perturbation a will change because ω and Ω change. This, however, is a second order effect.)

Consider a different problem: simple cooling from the steady-state temperature with the energy generation mechanism turned off. From equation (4) we find the cooling time $t_{\text{cool}} \equiv (T/\dot{T})_0 = 1/bT_0^3$. This cooling time is of the order of thousands to millions of years for the known pulsars[3]. The steady-state condition $\dot{T}_0 = 0$ then yields $a/\tau_0 = bT_0^4 = T_0/t_{\text{cool}}$.

The relaxation time τ has been discussed by Feibelman[4] and Harding *et al.*[5]. Here we adopt Feibelman's result, which can be written

$$\tau = (A/T)\exp\{T_a/T\} \tag{5}$$

In equation (5) A is a complicated function of density only, and T_a is the activation temperature for thermal creation of a vortex core excitation: $T_a = \Delta^2/\varepsilon_f k$ where Δ is the superfluid energy gap, ε_f the neutron Fermi energy and k the Boltzmann constant.

Now do perturbation theory about the equilibrium temperature T_0. Writing

$$T(t) = T_0[1 + \varepsilon(t)] \tag{6}$$

we obtain from equations (4–6) and the above relationships the perturbation equation for the temperature to first order in ε:

$$\dot{\varepsilon} = \{[1+\varepsilon]\exp[\varepsilon T_a/T_0] - [1+4\varepsilon]\}/t_{\text{cool}} \tag{7}$$

For infinitesimal perturbations we expand the exponential to find

$$\dot{\varepsilon} = \frac{\varepsilon}{t_{\text{cool}}}\left[\frac{T_a}{T_0} - 3\right] \tag{8}$$

In an instability $\dot{\varepsilon}$ would have the same sign as ε: hot stars are stable, but when the steady-state temperature drops below 1/3rd of the activation temperature the star becomes unstable, both relative to heating and to cooling. The growth time of the instability, however, is of the order of t_{cool}, which is too long to be interesting. Thus the star is essentially stable against infinitesimal perturbations for all temperatures.

The same is true for finite cooling perturbations ($\varepsilon < 0$). The case of a finite heating perturbation at low temperatures, however, is quite different. With $0 < \varepsilon \ll 1$ but $T_0 \ll T_a$ we obtain from equation (7)

$$\dot{\varepsilon} = t_{\text{cool}}^{-1}\exp(\varepsilon T_a/T_0) \tag{9}$$

in which the exponential can be much greater than unity. Such perturbations are strongly unstable. They grow more rapidly than any exponential with a growth time that becomes far less than t_{cool}.

As a numerical example, the activation temperature in a neutron star is of the order 10^8–10^9 K. Suppose we give the star a 10% thermal perturbation. Then the temperature increases with a growth time of the order of the cooling time at 10^7 K, but between 10^4 and 10^{40} times faster at 10^6 K.

As the temperature rises the frictional coupling between the pulsar angular velocity Ω and that of the superfluid ω will increase. The torque equations governing Ω and ω have been written in the two-component model by Baym *et al.*[1] (their equations (1) and (2)). The steady-state solution of these equations is $\dot{\omega}_0 = \dot{\Omega}_0$ and $(\omega - \Omega)_0 = I\tau_0|\dot{\Omega}_0|/I_c$. We will look at perturbations in the slowing-down rates $\dot{\Omega}$ and $\dot{\omega}$: write

$$\begin{aligned}\dot{\Omega} &= \dot{\Omega}_0[1 + \delta(t)] \\ \dot{\omega} &= \dot{\Omega}_0[1 + \gamma(t)]\end{aligned} \tag{10}$$

Combining equations (6) and (10) with the torque equations we obtain

$$\gamma = -(I_c/I_n)\delta \tag{11}$$

and the basic equation governing the fluctuations in the slowing-down rate of the pulsar (to first order)

$$\dot{\delta} = -\dot{\varepsilon}\frac{I_n}{I_c}\left(1 + \frac{T_a}{T_0}\right) - \frac{\delta}{\tau_0}\exp\left\{\frac{T_a}{T_0}\varepsilon\right\} \tag{12}$$

Equation (12) shows that in the absence of thermal perturbations the system is mechanically stable: with $\varepsilon = 0$ it reads $\dot{\delta} = -\delta/\tau_0$ which describes the classic spin-down problem of Baym *et al.* On the other hand, the mechanical response to the runaway heating described by equation (9) is, for small δ

$$\dot{\delta} = -\dot{\varepsilon}\left[\frac{I_n}{I_c}\left(1 + \frac{T_a}{T_0}\right)\right]. \tag{13}$$

Equation (13) shows that a thermal runaway (positive ε) is accompanied by a decrease in the slowing-down rate of the pulsar (negative δ). Because the factor in square brackets in equation (13) is greater than unity, the time scale for this decrease is even shorter than that for the thermal runaway.

Discussion

It is well known that, when born in a supernova explosion, a neutron star will be exceedingly hot: its temperature will greatly exceed the critical temperature $T_a/3$ separating stable from unstable configurations. It will therefore initially be stable against thermal perturbations. What is the subsequent thermal history of the star? I have previously[2] shown that the steady-state frictionally generated temperature of the star T_0 decreases as the pulsar ages. This means that the pulsar begins life in the configuration shown in Fig. 1*b*. The intersection point between the solid and dashed lines drifts towards lower temperatures as time passes; furthermore, as shown here, while this happens the slopes of these two lines become more nearly equal at their intersection point. When T_0 reaches $T_a/3$ the lines have become parallel at T_0. The star is now neutrally stable against thermal perturbations. When the temperature drops still further the situation switches to that sketched in Fig. 1*a*, and the star has become unstable.

Because the system is strongly unstable only for finite perturbations we must have some idea as to what could cause such initial perturbations. The smaller the necessary 'triggering' perturbation, however, the less seriously one need take this requirement. Equation (9) shows that a perturbation to the temperature greater than $\varepsilon_{\min} \simeq T_0/T_* \simeq T_0/(10^8\text{–}10^9)\text{K}$ will grow rapidly. For plausible stellar temperatures this can be quite small. Note also that in the binary X-ray pulsars accreting matter can easily supply the necessary perturbations. Furthermore, in the isolated pulsars a neutron starquake may release enough thermal energy to trigger the instability. As a numerical example, Baym and Pines[6] estimated that $\simeq 10^{41}$ erg can be released in a typical 'small' starquake. At a temperature of 10^6 K this yields a 100% change in the temperature for reasonable specific heats: the growth time for the subsequent runaway is of the order of exp{1,000} shorter than the cooling time.

What is the ultimate fate of the instability? As the temperature increases the pulsar tends to lock rotation with the more rapidly rotating superfluid. (The decrease in slowing-down rate described above is the first stage of this process.) There is no reason to believe that once the perturbation has become large this behaviour suddenly ends. In fact, it will end only when the two components have rigidly locked together. At this point the frictional generation of heat ceases and the star commences to cool. By how much has the pulsar sped up in this process? From considerations of angular momentum conservation it is easy to show that the fractional change in pulsar period will be

$$\frac{\Delta\Omega}{\Omega} = \frac{I_n}{I}\left(\frac{\omega_0 - \Omega_0}{\Omega_0}\right) \tag{14}$$

that is it is of the order of the initial fractional lag between superfluid and crust. Detailed studies[2] show that this lag can be quite large: the mechanism seems capable of producing large period jumps such as have been observed in the Vela pulsar. At any rate, the fact that a sufficiently cool pulsar can exhibit the instability demonstrates that its rotational state must be radically different from that of a hotter one.

I thank A. G. W. Cameron who first pointed out that instabilities might occur in the process of frictional heating, also R. A. Guyer for discussions, and the Library of the British Council in Kathmandu (Nepal) for hospitality. This research has been supported in part by a grant from the Research Corporation.

Massive ore-grade zinc, copper and iron sulphide deposits have been found at the axis of the East Pacific Rise. Although their presence on the deep ocean-floor had been predicted there was no supporting observational evidence. The East Pacific Rise deposits represent a modern analogue of Cyprus-type sulphide ores associated with ophiolitic rocks on land. They contain at least 29% zinc metal and 6% metallic copper. Their discovery will provide a new focus for deep-sea exploration, leading to new assessments of the concentration of metals in the upper layers of the oceanic crust.

THE area of the deposits of ore-grade zinc, copper and iron sulphide was explored and sampled in February–March 1978 by the manned diving saucer CYANA during the expedition CYAMEX[1]. The expedition, the only submersible diving programme that has so far been conducted on the East Pacific Rise (EPR), is part of the French–American–Mexican project RITA (Rivera–Tamayo), a 3-yr study devoted to detailed geological and geophysical investigations of the EPR crest. The ore deposits were sampled in water depths of close to 2,620 m at two neighbouring sites near 20° 54′ N 109° 03′ W, (refs 2–5) about 90 km north of the Rivera transform fault and 240 km south of the Tamayo transform fault (Fig. 1). Three dives of Cyana (CY 78–06, 08 and 12) crossed the two sampling sites, and we collected samples during two of these dives (CY 78–08 and 12). However, during all dives in the EPR axial zone, signs of hydrothermal activity were seen, including colonies of dead giant clams, fields of pillow lavas with pronounced colour-staining at the base of pillows, and coloured deposits on exposed scarp surfaces of normal faults and open fissures[1]. Coral-like growths, possibly of native sulphur, occur in other locations, including a sedimented fault-scarp about 1.0 km to the west of where the sulphide ores were sampled.

Sampling sites

The two sites where the sulphides were sampled lie on the lightly sedimented flanks of steep-sided structural depressions, about 20–30 m deep, 20–30 m wide, and about 600–700 m west of the

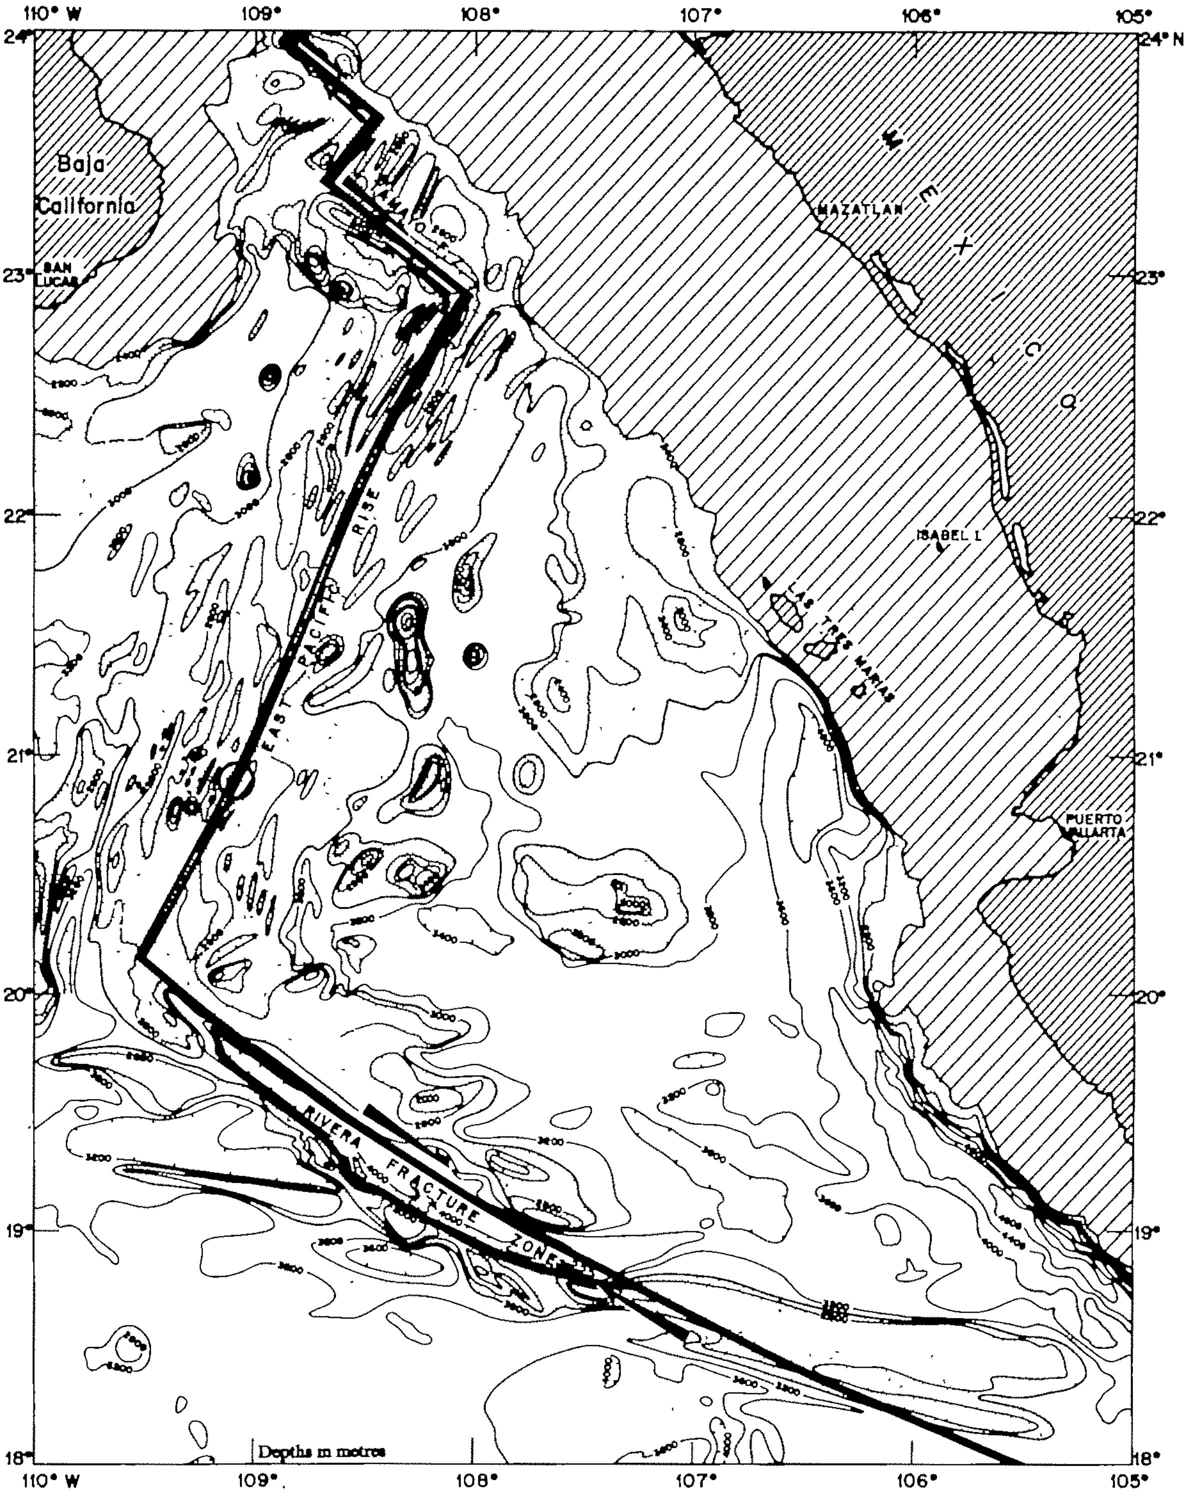

Fig. 1 Setting of the axial zone of the East Pacific Rise where the sulphide ore deposits were explored and sampled (circle).

axis of the 'extrusion zone' where the youngest lavas occur. Whereas the extrusion zone is marked by a 50 m-high sediment-free discontinuous ridge with no fissures or faults, the structural zone within which the sulphide deposits are located is a 1.5 km wide tectonically active band of fissured and/or faulted terrain, the fault pattern being typically of the small horst and graben type and with all the active structures running parallel to the local strike of the EPR.

The massive sulphides were sampled from various parts of tall (up to 10 m-high), extremely irregular columnar edifices about 5 m in diameter (Figs 2 and 3). At one site, explored in relative details during dive CY 78–08 (Fig. 2), the vertical edifices are 4–5 m apart and are aligned along a direction of 025° over a distance of at least 50 m, in gullies cutting through the 045°-trending, westwards-facing scarp of a structural depression (graben). The second site, explored during dive CY 78–12, is about 200–300 m away and lies on the eastwards-facing flank of a possibly older graben. Here, there is more sediment cover, there are yellow-coloured coral-like growths and the edifices seem to be more indurated. The true spatial relationship of the two sampled sites is not established because of navigational difficulties during dive CY 78–12.

The along-strike extent of the sulphide mineralisation is not known. However, during dive CY 78–08 the graben was followed for about 100 m to the SSW (200°) where it became a 2–3 m wide open fissure with truncated pillows entirely stained by ochre and red-brown deposits exposed on the scarp. The eastern lip of the fissure has small (about 0.5 m high), sponge-like porous edifices and coral-like, bright yellow growths on sediment between pillows. Further south the fissure narrows and is bare of any hydrothermal deposits.

In general, the vertical edifices are built on a pillow lava terrain covered with a light dusting of sediment, the colour of which suggests some contribution of weathering products from the deterioration of the columnar edifices themselves. The edifices are variegated, the dominant colours being ochre, red, yellow, brown, white and black. They are porous and their entire mass is composed of a labyrinth of small channels or tubes separated by thin walls. Their internal structure can be compared to that of a sponge or a mass of clinker or brains. The framework of the edifices is made up of both amorphous, white translucent silica (which has been seen bare in one case) and the sulphides. The presence of open vents on top of the edifices demonstrates that they are constructional features built directly on the ocean crust. For this reason, we described them as hornitos when first observed. The tubes, conduits and channels pervading the mass of the edifices presumably represent the passages through which hot, metal-laden solutions circulated on their exit from the sea floor.

Three other modes of mineralisation occur besides the spectacular vertical edifices: (1) flattish incrustations coating the moderately steep slopes with a rugose, heterogeneous surface texture made up of the same material as the tall edifices; (2) bright yellow or orange, 10–20 cm wide conelets built on sediment and with small holes at their tops and which lie around the large edifices; (3) yellow and red-brown travertine-like flows draping the near-vertical scarps of the graben that contains the row of vertical edifices. No unequivocal bottom-water temperature anomaly was observed during the exploration of any of the mineralised structures, suggesting completed or quiescent hydrothermal activity.

The material collected from each of the two sampling sites was separated on board ship according to colour and shape, giving a total of 14 samples (three from the site sampled during dive 8 and 11 from that sampled during dive 12). Some of the 14 samples thus designated comprise several subsamples or collections of fragments. A total of 215 subsamples and 11 boxes of small fragments were separated in the laboratory. The samples are very heterogeneous and complex, and no attempt is made at this stage to give a full description of them. We describe here only the gross mineralogy and give an indication of the chemistry of a few important subsamples.

Mineralogy and chemistry

The material consists of friable and porous compounds that are easily fragmented; thus some subsamples are as large as 7 cm in diameter but many are smaller, and some consist of debris with diameters of one to a few mms, or are essentially powder. The subsamples are variegated: yellow to ochre-coloured, grey and blue metallic hues, and grey, bronze red and white reflections. The ochre-coloured material ranges from pale yellowish orange (10 YR 8/6) and moderate yellowish brown (10 YR 5/4) to moderate brown (5 YR 4/4) and from blackish red (5 Y 2/2) to moderate red (5 R 4/6). Most subsamples show well developed cylindrical tubes that display a concentric zonation of medium grey (N 5) layers on the outside to dark gray (N 3) and white (N 4) layers inside. Other tubes are composed of the lighter-coloured moderately brown material (5 YR 4/4). The inner walls of some of the tubes are lined with shiny, silvery deposits that are in part microcrystalline, whereas others are covered only by reddish deposits. Some tubes are lined with black deposits inside and coated with yellow and ochre-coloured deposits outside. Other tubes are filled or partially filled by black material. The tubes are variable in size (0.1–1.5 cm in diameter and up to 8 cm in length) and are irregularly scattered throughout the subsamples. Some tubes are closely spaced in a parallel fashion.

Five pieces from four samples were selected for macroscopic examination and preliminary mineralogical and chemical analysis. Four of the pieces (Cyp 78-12-38A-2, 38A-1-a, 40A-a and 40B) are relatively dense and consist mainly of sulphides. The fifth (Cyp 78-08-14A-1) is oxidised and less dense than the others. Subsample Cyp 78-12-40 B is elliptical in shape; the convex side is coated with dark, heavy sulphide aggregates and

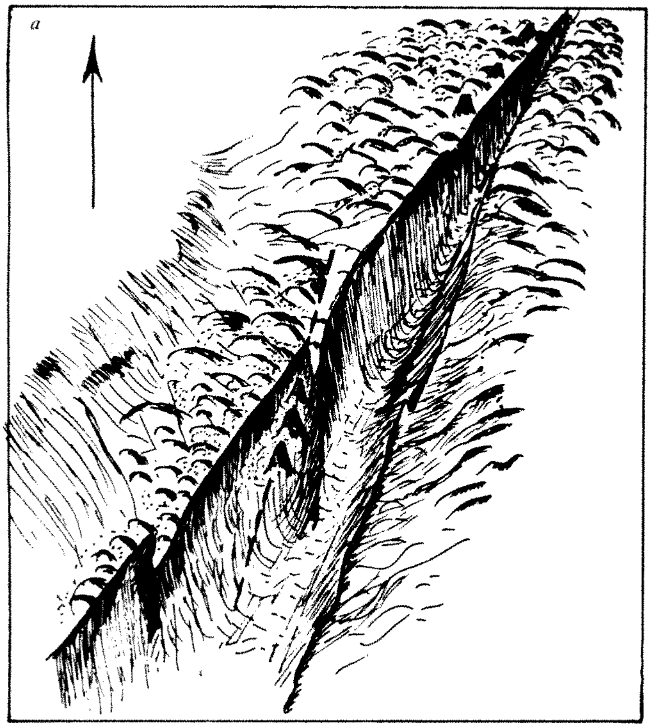

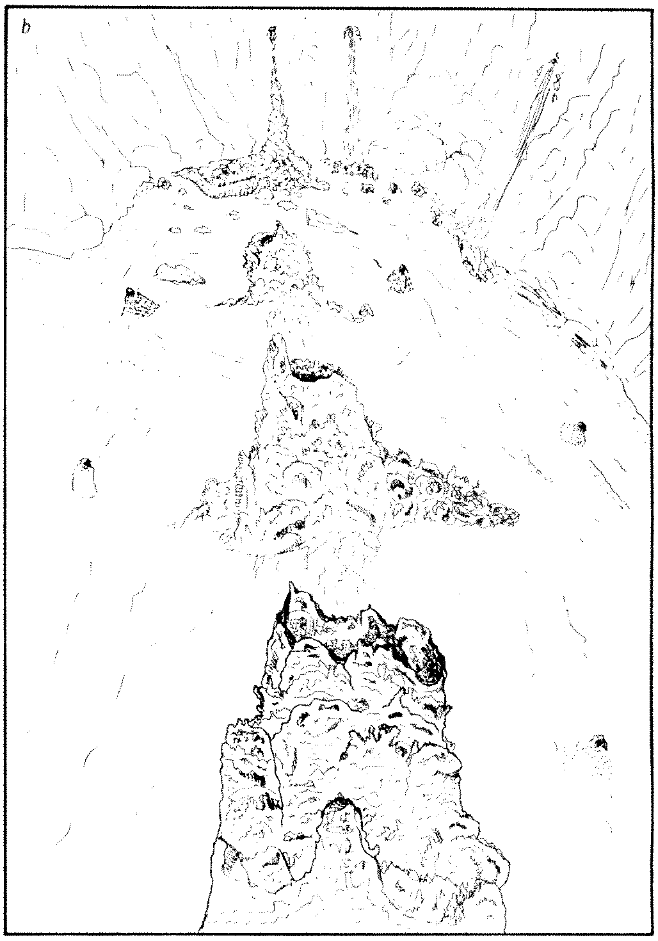

Fig. 2 *a*, Overall sketch of the 225° trending structural depression with a small gully or re-entrant trending 205° that crosses the east wall of the graben (dive CY 78-08). The width of the graben is about 20–30 m and narrows towards the SSW. The arrow points towards the south. *b*, Artist's view from CYANA's porthole of the site of sulphide ore edifices on the eastern flank of a structural depression (dive CY 78-08). The view is towards the south. The hornito-like edifices are aligned along 205 in a gully cutting across the graben. The spacing between 'hornitoes' is about 5 m. The small conelets associated with the vertical edifices are shown as well as the flows of hydrothermal material on the vertical scarp in the cul-de-sac of the small gully. All the sulphide material was sampled from the porous edifices.

there are patches of greenish-yellow dust with a strong odour of sulphur. The concave surface of the specimen is coated by moderate yellowish brown and brownish ochre material. Small empty tubes (0.1–1 cm in diameter) are also seen. Specimen Cyp 78-12-40A-a is a nearly black material with circular tubes, one of which has its internal wall coated by a brass-yellow lamella. Concentric zonation of dark (outside) and white (inside) lamellae is exhibited by another adjacent tube. Specimen Cyp 78-12-38A-2 is dark grey with remnants of tubes and patches of yellowish-green, green and purple brown material similar to the other dark sulphide aggregates. Specimen Cyp 78-12-38A-1-a is a massive aggregate of black sulphide-rich material which is extremely friable and porous and gives off a strong odour of sulphur. It contains specks of yellowish-green material which could represent a sulphur oxide compound. Subsample Cyp 78-08-14A-1 is a moderate brown to blackish red to ochre-coloured powdery material with abundant relicts of tubes, some of which are open and continuous across the specimen, while others are filled by a yellowish brown material. Sulphide material coats some of the walls of the empty tubes.

The mineralogy of the material was determined by X-ray diffraction after microscopic examination in reflected and transmitted light (Table 1). The ochre-coloured material consists mainly of amorphous iron-oxide. The oxides are reddish and yellow and are found in the interstices of the sulphide grains, resulting primarily from secondary alteration of the sulphides.

The sulphide phases consist mainly of sphalerite and pyrite with minor chalcopyrite and marcasite. The sulphides are represented by agglomerates of intimately associated, well-crystallised phases and amorphous material. The most common form encountered in the samples is an octahedron. Tetrahedra characteristic of sphalerite, cubes of pyrite, bipyramids, sphenoids characteristic of chalcopyrite, and tabular crystals with polysynthetic twins (probably of sphalerite) are also observed. Globular and reniform associations, probably consisting of chalcopyrite and pyrite, with anisotropic clay-size material are commonly associated with the well-crystallised sulphides.

The chemistry of the five specimens was determined qualitatively by X-ray fluorescence (XRF) spectrometry (dispersive) and quantitatively by atomic absorption spectrometry (Table 1). The XRF analyses show the presence of abundant zinc, iron, copper and sulphur and of lesser quantities of several other elements including cobalt, lead, silver and cadmium. The material used for atomic absorption analyses (100 mg to 1 g) should be reasonably representative of the subsamples which weigh from 19 to 91 g. The analyses show two principal modes: one zinc-rich (23–28.7%) and the other iron-rich (19.9–42.7%). Three specimens are copper-rich (2.2–6%) and we note the absence of manganese even as a minor element.

The subsamples can be divided into two major types according to their macroscopic features, mineralogy and chemistry: (1) the dark-coloured and porous, zinc, iron and copper sulphides in the form of sphalerite + marcasite, pyrite and chalcopyrite, with a skeleton made up of a white unidentified material; and (2) the fragile, pulverulent ochre-coloured material made up of amorphous iron oxides. The widespread occurrence of pure sulphur on many of the subsamples suggests that the small yellow conelets and bright yellow crystal-like growths around them, which are associated with the larger variegated edifices on the sea floor, might represent massive concentrations of native sulphur.

The occurrence of sulphide mineralisations on the sea floor in an active tectonic region directly associated with an accreting plate margin can best be explained by a model in which the deposits formed within the discharge zone of a hydrothermal circulation system involving seawater as the convecting fluid[6–12]. A similar explanation has been put forward for the genesis of ophiolitic sulphide ore deposits on land, which share many common characteristics with the EPR deposits[6,9–17]. A typical example of the ophiolitic sulphide ores is found in Cyprus[6,10,12,13–15,17–20].

The Cyprus deposits occupy basin-like depressions in basalts and occur as irregular, elongate lenticles or lens-shaped bodies of massive sulphide ores (pyrite + chalcopyrite ± sphalerite ± marcasite with minor galena, pyrrhotite, gold and silver). Like the EPR deposits, which are also restricted to structural lows, they accumulated on the sea floor before the first sediments were deposited and in some deposits the ore is overlain by pillow lavas and sediments. An interval of 10^5 years has been tentatively proposed for the formation of the Cyprus ores[12]. The EPR deposits are adjacent to the main axial extrusion zone but there is direct evidence from the dives that lava can also be emplaced within the horst and graben tectonic zone so that burial of the deposits by off-axis volcanism is possible. We estimate the age of the EPR deposits to be $<1–2\times10^4$ years using as a guide the fact that they occur on crust whose age is theoretically $1–2\times10^4$ years, based on spreading rate.

The Cyprus deposits can show alteration near the top to a geothitic material or to pyrite-bearing chemical sediments (ochres) enriched in silica and hydrated iron-oxides. The ochreous components of the EPR deposits are probably gossans and represent products of submarine weathering of the sulphide ores. The Cyprus deposits display prominent metal zoning with zinc-rich bodies lying deep in the Lower Pillow Lavas and larger copper-rich bodies at shallower levels in, or at the top of, the Upper Pillow Lavas. We have no evidence yet of whether or not there is metal zoning within the metre-scale sulphide cones of the East Pacific Rise. There are indications of some zoning at the scale of the samples. The sulphides on Cyprus exhibit primary breccia textures in the upper part and are massive in the lower part. Ore textures similar to the sponge-like texture of the EPR deposits have not been described in Cyprus or other Cyprus-type sites but the Cyprus ores are said to be very porous. The fragile tubular and heterogeneous texture of the EPR sulphides may not be preserved in the geological record or possibly they represent the equivalent of the upper breccias in Cyprus ores. Finally, the Cyprus ore deposits are separated by a mean distance of about 2.5 km in a direction perpendicular to the strike of the sheeted dikes and thus to the strike of the fossil spreading centre. The hydrothermal sulphur/sulphide sites of the EPR are separated by about 1 km in a direction transverse to the EPR axis.

Conclusions

Despite the differences in detail and in scale between the East Pacific Rise deposits and the Cyprus ores, there are enough general similarities in the type and style of metal concentration to regard the EPR deposits as a modern analogue of the zinc-rich cupriferous massive sulphide deposits associated with ophiolite complexes. The EPR ore deposits, which have their primary features still preserved and which have been emplaced in a well defined geological setting directly associated with plate accretion, should shed a new light on the characteristics of, and genetic models for ophiolitic sulphide ore deposits such as found in Cyprus[6,10,12,13–15,17–20], Newfoundland[16], California[10], Turkey[10], and Italy[9]. The EPR deposits further demonstrate that modern ocean floor sulphide deposits are not restricted to the initial stages of ocean rifting, as suggested by the Red Sea deposits.

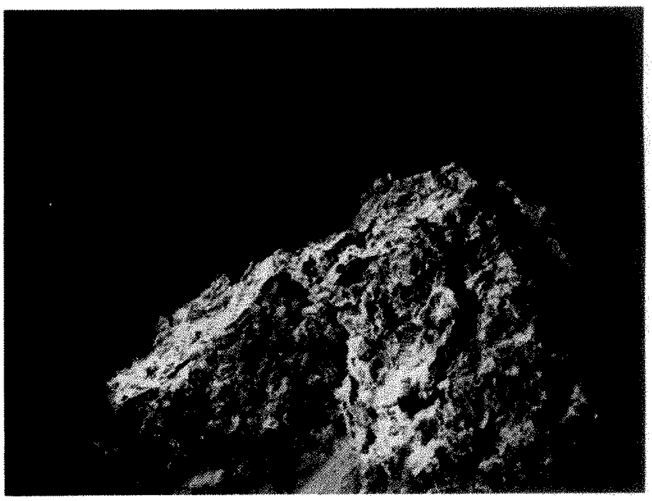

Fig. 3 Photograph of a variegated hornito-like edifice taken during dive CY 78-06. The diameter of the edifice is ~2 m. A second edifice can be seen in the background.

The metal-rich brines and muds that are found in the axial region of the Red Sea[21], or beneath the Salton Sea Trough[22] (a northwards extension of the Gulf of California) show iron-rich layers overlying a sulphide horizon with sphalerite and less abundant chalcopyrite, pyrite and marcasite. In contrast with the sulphide-rich, Mn-deficient EPR deposits, the other metalliferous deposits encountered in Mid-Ocean Ridge settings are essentially Fe–Mn concretions, Fe–Si rich clay material, and occasional pure MnO_2 deposits[23–26].

Mid-Ocean Ridge sulphides and ferromanganese deposits attributed to a hydrothermal origin are all chemical precipitates which form at the basalt–seawater interface when hot seawater solution, laden with Fe, Mn and other metals stripped at 'high temperature' (see refs 8, 10, 12) from the ocean crust, debouches onto the ocean floor. Sulphides, such as the EPR deposits, can be preserved either if the bottom waters are anoxic or if the sulphide deposits become rapidly buried under sediments or lavas. The ochres, such as those of the East Pacific Rise, result from the oxidation of the iron sulphide. The Fe–Mn deposits (umbers) encountered in the FAMOUS area, in the Galapagos and in the Gulf of Aden may be the product of a weaker flow of the convecting fluid although many other factors (such as temperature, redox conditions, and fugacity) may be critical. Sulphides in such settings would be deposited subsurface. Indeed, this is suggested in the FAMOUS area by the presence of pyrite in the deposits near the vents[24]. It is not clear whether the flow rate of ocean floor convective systems depends primarily on the spreading rate but it seems from the contrast between the RITA and Galapagos areas and the FAMOUS area that hydrothermal activity is more prevalent in higher spreading-rate environments.

It will be a test of ingenuity to assess the surface distribution of metal-rich deposits on the Mid-Ocean Ridge, let alone their distribution at depth. Furthermore, there is the problem that unusual circumstances might be required for their preservation. However, the discovery in the RITA area shows that metal deposition is not restricted to young oceans and that the axial zones of medium-fast (and perhaps fast) ridges are not only factories of oceanic crust and lithosphere but also plants for the concentration of heavy metals through leaching of the oceanic crust in zones of intense hydrothermal activity and deposition on the basaltic floor. Indeed, the EPR deposits throw a fresh light on the whole question of the concentration of metal deposits of the oceanic crust.

In the future one might envision that submarine metalliferous ore deposits are distributed in quasi-continuous, linear strips several thousand kilometres in length along the axis of the fast-spreading East Pacific Rise and south-east branch of the Mid-Indian Ocean Ridge. Certainly we will have to re-examine our estimates of the mineral resources which lie within reach on top of the bare crust of the Mid-Ocean Ridge. Slow ridges seem so far to yield only Fe and Mn-rich deposits in fracture-zone terrain; thus, the sites of priority interest for further sulphide ore exploration are the fast as well as super-fast ridges.

We thank F. Spiess, coordinator of Project RITA, CNEXO, C. Riffaud, X. Le Pichon, J. Debyser, and the Comité Scientifique des Submersibles for encouraging French participation in the Project and for sponsoring the Cyamex expedition. We thank C. Caillart, R. Kientzy, H. Leroux, G. Arnous, J. M. Nivaggioli, D. Semac, W. Marquet, P. Plasseraud, J. Porteous, H. Lossouarn, the technical team of Cyana, captain Y. Langlois and the officers and crew of the M/S NADIR who all contributed to the success of the dives; also M. Février, J. Etoubleau and G. Floch for technical assistance and A. Grotte and N. Guillo for help with the preparation of the manuscript, and G. Pautot for his interest. We also thank J. Bischoff for his participation in the initial identification of the samples as massive sulphides and for stimulating the study. The expedition was funded by CNEXO with contributions from NSFm USGS, Woods Hole Oceanographic Institution, National Geographic Society and the Mexican Government.

Friction and seismic attenuation in rocks

Kenneth Winkler & Amos Nur
Department of Geophysics, Stanford University, Stanford, California 94305
Michael Gladwin
Department of Physics, University of Queensland, St Lucia, Brisbane, Australia 4067

Precise experimental results, combined with theoretical predictions, indicate that seismic energy loss caused by grain boundary friction is important only at low confining pressure and at strains greater than about 10^{-6}. *Since these conditions are generally not encountered in seismology, frictional attenuation is not important* in situ. *Other mechanisms such as fluid flow must dominate seismic attenuation in the upper crust.*

FAR more information about the constitution of the Earth is obtained from seismic studies than from all other geophysical methods combined. Of the two main aspects of wave propagation—velocity and attenuation—knowledge of velocities has provided most of our information about the Earth. Attenuation data is of much more limited use, partly because it is difficult to obtain, but mainly because it is difficult to interpret in terms of rock properties. This is due primarily to our lack of understanding of the physical processes involved in the attenuation of seismic waves. (Here we are not considering apparent attenuation caused by geometrical spreading, partial reflections and so on, but are only interested in those processes that convert seismic energy into heat.)

Many different techniques have been used to study the attenuation of acoustic waves propagating through rock. Although much data has been collected, no well-defined mechanism of energy loss has yet been firmly established on both experimental and theoretical grounds. One of the most intuitively appealing and widely discussed mechanisms proposed for seismic energy loss is based on simple Coulomb friction. In this mechanism the passing wave causes sliding at grain boundaries or across crack faces, thereby doing work against friction and converting seismic energy into heat. Since frictional heating is rate independent, it seems to account for the reported observation that the specific dissipation function[1], Q, is nearly independent of frequency. Friction also seems to explain why the introduction of cracks into a crystalline solid increases attenuation. The most severe criticism of a frictional mechanism is, however, that the mechanism is inherently nonlinear. This means that the velocity and attenuation of a sinusoidal wave will depend on how it is combined with other waves. It has been found that at large strain amplitudes ($>10^{-6}$) nonlinear effects such as cusped hysteresis loops[3,4] and amplitude-dependent velocity and attenuation[3,5,6] can be observed, but these effects disappear at strains more typical of seismic waves.

Using both theoretical arguments and experimental results, several authors[2,7–9] have expressed doubts about the validity of a frictional attenuation mechanism. For instance, Savage[7] has suggested that frictional effects should be important only at large strains where displacements across crack faces are sufficiently large for the concept of macroscopic friction to be valid. Despite these criticisms, frictional losses are often used to interpret experimental observations[10–12]. To clarify the role of friction in seismic wave attenuation, we carefully investigated the dependence of velocity and Q on strain amplitude. We were able to identify the range of conditions for which frictional losses may be significant and our results show that the frictional mechanism is generally not important for seismic waves in the Earth.

Theory of frictional losses

Two types of frictional attenuation models have been proposed. Walsh[13] developed a model based on thin elliptical cracks in which frictional sliding occurs between crack faces. Models based on spheres in contact were developed by Mindlin and Deresiewicz[14] and by White[15]. Mavko[16] has reviewed these theories and extended the contact model to more general geometries. The most significant feature of Mavko's model (which it shares with that of Mindlin and Deresiewicz) is that it predicts Q^{-1} to be proportional to strain amplitude. It has been

0028–0836/79/0277—0528$01 00

found experimentally that frictional behaviour is often described by an equation of the form[17]

$$\sigma_f = S + \gamma\sigma_n$$

where σ_f is the frictional force, S is the cohesive shear strength, γ is the coefficient of friction and σ_n is the normal stress across the sliding surfaces. The contact models predict that attenuation will decrease as either γ or S increases. Attenuation will also decrease as σ_n increases and the sliding interfaces are effectively locked together.

In addition to the effects on attenuation, all frictional models predict that stress–strain loops will have discontinuities in slope at maximum strain. This is a static hysteresis effect. As stress reverses direction there is a simultaneous reversal of elastic strain and a delayed reversal of sliding strain.

Table 1 Sample descriptions

Sample	Dimensions (cm)	V_E/f_E (km s^{-1} Hz^{-1})	Porosity
Massilon sandstone	100×2.0×1.9	2.000	22%
Berea sandstone	101.6×2.54× 2.54	2.032	20%
Sierra White granite	101.6×2.54× 2.54	2.032	1%
Vycor 7930 glass	91.4×1.5 diam.	1.828	28%
Lucite (plastic)	98.7×1.51 diam.	1.974	0%
Aluminium	100×2.22×2.22	2.000	0%

Vycor 7930 porous glass is made by Corning Glass Works; the average pore size is 4 nm.

Past observations of frictional losses

Several of the predicted effects of frictional attenuation models have been observed. Energy loss has been found to increase with strain amplitude at large strains in rock[3] as well as between sliding glass and metal surfaces[19,20]. It has been shown that at low strains ($<10^{-6}$) attenuation is nearly constant[3] and that variation with strain amplitude occurs only at larger strain. Some attenuation in metals at large strain is associated with dislocation mechanisms, but this does not explain all of the observations.

Discontinuities in the slope of stress–strain loops have been observed in large strain quasi-static experiments[3,4]. These have been described as cusped loops. It has recently been shown[21] that as strain amplitude decreases, the cusped loops become elliptical at strains approaching 10^{-6}. It is interesting that two of the effects predicted by frictional attenuation models, amplitude-dependent Q and cusped hysteresis loops, both seem to disappear below the same strain amplitude.

It is also commonly observed that increasing confining pressure causes attenuation to decrease[22,23]. This is predicted by frictional models, but it is also predicted by many other possible mechanisms of energy loss and so by itself does not provide evidence for frictional loss.

New observations of frictional losses

We are using the well established bar resonance technique[22,23] to measure both attenuation and velocity in long thin bars of rock. (Experimental details will be presented elsewhere.) An important feature of our experiment is that pore pressure is controlled independently of confining pressure. This has not previously been achieved in a resonance experiment. The length of the samples (~1 m) puts the fundamental resonance frequencies at roughly 500–1,500 Hz. Sample dimensions are given in Table 1. Resonance frequencies are measured to 1 part in 10^3 and converted to velocities using the relation $v = 2Lf$ where L is the length of the bar. Geometric corrections given by Spinner and Tefft[24] are negligible for our samples in extensional resonance. Strain amplitudes are measured with crystal phonograph pick-ups calibrated against semiconductor strain gauges.

Table 2 Tests for nonlinear behaviour in various materials (negligible changes of Q_E and V_E are found for materials where frictional mechanisms are inoperative)

Material	Strain amplitude	Q_E	Velocity (m s^{-1})
Lucite	1.43×10^{-6}	23.4±0.3	2,108
	3.04×10^{-8}	23.2±0.4	2,108
Vycor	2.84×10^{-6}	437±2	3,345
	1.58×10^{-8}	435±4	3,345
Aluminium	2.41×10^{-6}	34,800±300	5,102
	2.46×10^{-8}	35,200±400	5,102
Granite	1.44×10^{-6}	185±1	3,629
	4.15×10^{-8}	204±1	3,637
Massilon sandstone	2.10×10^{-6}	107±1	1,820
	1.55×10^{-8}	138±2	1,834
Berea sandstone	2.10×10^{-6}	103±3	1,937
	2.30×10^{-8}	140±2	1,955

Attenuation measurements can be made either by plotting resonance peaks ($Q = f/\Delta f$) or by measuring the time constant of resonance decays ($\tau = Q/\pi f$). Before using either technique, resonance peak shapes were carefully observed to insure the purity of the resonances. For convenience, all attenuation data presented in this article was taken with the resonance decay technique (except as noted in Fig. 1). The precision of the attenuation measurements is 1% and the estimated absolute accuracy is 5–10%. Both torsional (shear modulus) and extensional (Young's modulus) resonance modes show similar nonlinear behaviour at large strains. Only extensional data (taken at the fundamental resonance) will be presented here.

Data for dry Massilon sandstone as a function of resonant strain amplitude are shown in Fig. 1. At strains below 5×10^{-7} both attenuation (Q^{-1}) and velocity are nearly independent of strain amplitude, whereas at relatively large strains ($>10^{-6}$) there is a clear increase in attenuation and decrease in velocity. Of the two measured quantities, Q^{-1} is more sensitive to strain

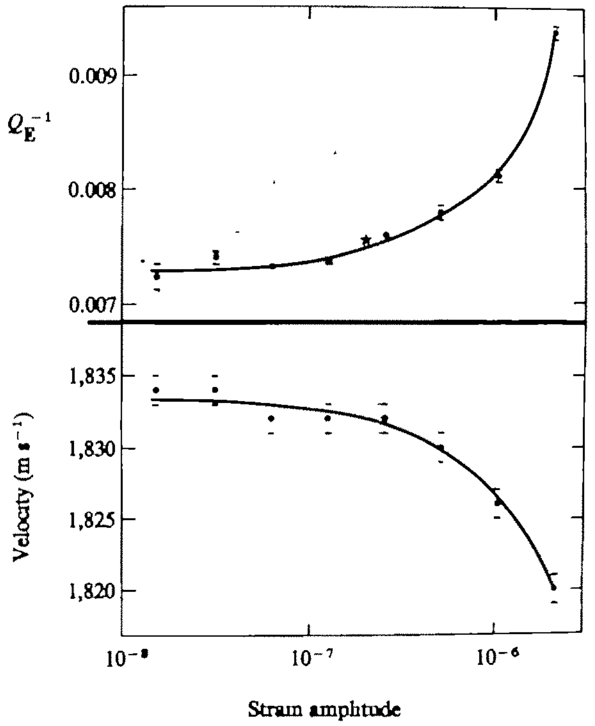

Fig. 1 Variation of attenuation (Q^{-1}) and velocity with strain amplitude for dry Massilon sandstone in extensional resonance. ★, The value found from the resonance peak half-width using the relation $Q^{-1} = \Delta f/f$.

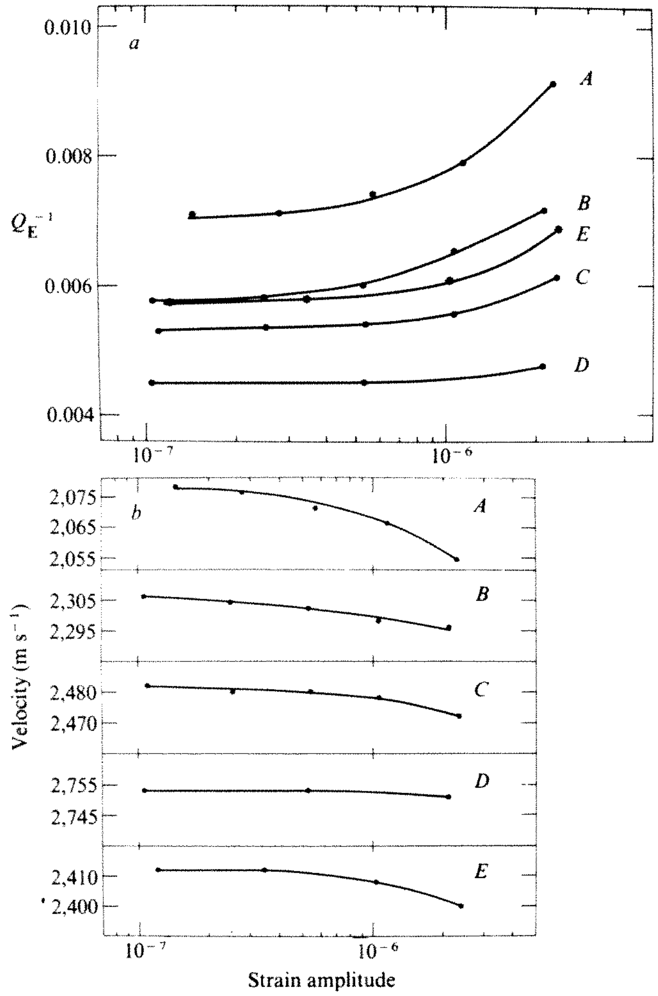

Fig. 2 *a*, Attenuation in dry Berea sandstone as a function of strain amplitude, confining pressure (P_c) and pore pressure (P_p). Helium was used as the pressure medium. (*A*) $P_c = 10$ bar; (*B*) $P_c = 20$ bar; (*C*) $P_c = 30$ bar; (*D*) $P_c = 50$ bar; (*E*) $P_c = 50$ bar, $P_p = 30$ bar. *b*, Extensional velocity of Berea sandstone. Data correspond to the attenuation data shown in (*a*).

amplitude than is velocity, varying by 19% and 0.7%, respectively. The similarity of the curve shapes suggests an underlying relationship between the amplitude dependence of Q^{-1} and velocity.

We have further investigated these nonlinear effects by varying effective stress—the difference between confining pressure and pore pressure. Figure 2 shows data for a jacketed sample of Berea sandstone, with helium used for both confining pressure and pore pressure. As confining pressure is increased from 10 to 50 bar (curves *A*–*D*), the variation of both Q^{-1} and velocity with strain amplitude gradually decreases. At a constant confining pressure of 50 bar (curves *D* and *E*) increasing pore pressure restores the dependence on strain amplitude. In Fig. 2*a* curves *B* and *E* show that Q^{-1} is almost a unique function of effective stress at a given strain amplitude.

The effects of changing water content on Q^{-1} in Berea sandstone are shown in Fig. 3. The data for partially saturated rock at very low saturation were obtained at ambient room conditions. Data for 'dry' rock were obtained after drying the sample in a vacuum oven, and the data for saturated rock after saturating the sample with distilled water. The most noticeable feature is that the addition of water greatly increases the attenuation. This effect, which is associated with a fluid flow mechanism, will be discussed more thoroughly elsewhere[29]. Of greater interest here is that the addition of a small amount of water greatly increases the variation of Q^{-1} with strain amplitude, whereas continued addition of water causes a smaller additional variation in Q^{-1}. This is indicated by the brackets in Fig. 3 which show the difference between Q^{-1} at a strain of 1.7×10^{-6} and the constant value of Q^{-1} at low strains.

To find out which structural features of a material are related to these nonlinear effects, we experimented with materials having physical compositions different from sandstone. Table 2 shows data for various materials measured at both large and small strain amplitudes. Lucite and aluminium show no evidence of any change in velocity or attenuation with strain (to within experimental uncertainty) although their respective Q values span more than three orders of magnitude and their internal structures are quite different. (The values of Q for aluminium are probably underestimates because they are at the limits of sensitivity of our system.) There is also no variation in the values for dry Vycor glass. Under the scanning electron microscope Vycor appears to be composed mainly of glass beads ~50 nm diameter. The contacts were beyond the resolution of the SEM used, (86,000×), but presumably the particles are welded together since they formed simultaneously from the melt. The flat cracks and partially cemented grain boundaries commonly found in rocks are probably scarce in Vycor. Table 2 also includes data for a room dry granite sample which shows the same nonlinear effects found in sandstone.

Discussion

The data we have presented, together with the existing data we have discussed, provide strong support for the existence of a frictional attenuation mechanism in rock at large strain amplitudes and low effective stresses. Every predicted feature of the contact frictional loss mechanism has been observed experimentally. At large strains ($>10^{-6}$) Q^{-1} increases with increasing strain amplitude and the amount of the variation in Q^{-1} is strongly influenced by effective stress. A stress of 50 bar is enough to virtually eliminate the strain dependence at the strains and in the rocks which we have used.

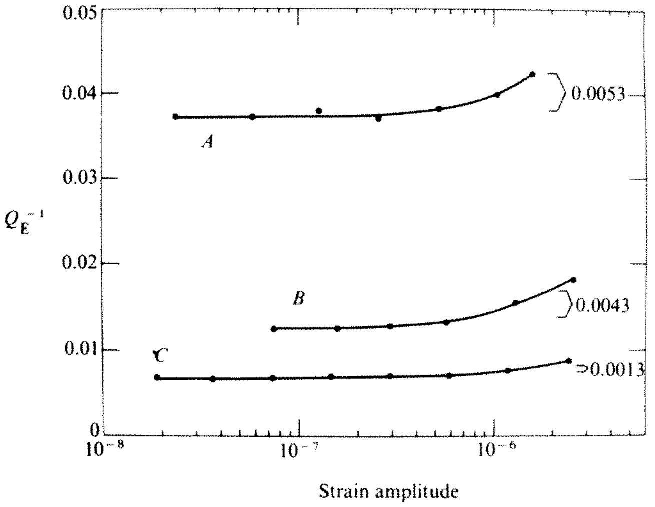

Fig. 3 Attenuation in Berea sandstone at various degrees of saturation as a function of strain amplitude. Brackets indicate frictional component of energy loss. *A*, saturated; *B*, partially saturated; *C*, dry.

The effect of water on the amplitude dependence of Q^{-1} is probably caused by water changing the frictional properties of the sliding interfaces. Figure 3 provides evidence for this. Adding a small amount of water to the sample presumably wets most of the internal surfaces, causing a slight increase in the low strain, linear attenuation (a fluid flow mechanism) and a large increase in the nonlinear, frictional component of attenuation. The addition of more water fills the remaining pore space, thus enhancing the flow losses but only slightly increasing the frictional energy loss.

The observations of cusped stress–strain loops[3,4] at strains greater than 10^{-6} also indicate that frictional sliding is occurring. It is significant that all of the evidence for a frictional attenuation mechanism disappears below strains of the order of 10^{-6}. The cusped loops become elliptical and Q^{-1} becomes independent of strain amplitude. The implication is that at low strains attenuation is caused only by linear loss mechanisms. At larger strains, nonlinear frictional losses become observable. This leads to the question of why a strain of 10^{-6} or larger is needed before frictional attenuation is observed. We can assume that displacements across crack surfaces must be at least comparable with inter-atomic spacings ($\sim 10^{-8}$ cm) for friction to be present. A shear strain ε will produce a displacement d across the sides of a crack of length L given approximately by $d = \varepsilon L$. If $d = 10^{-8}$ cm and $\varepsilon = 10^{-6}$, then we find that $L = 10^{-2}$ cm. A crack length of 10^{-2} cm may well be a rough upper bound to the majority of crack lengths found in rock. Hadley[25] reported that in Westerly granite only 7% of the observed cracks had lengths greater than 10^{-2} cm and none were longer than 3×10^{-2} cm. Therefore, at strains below 10^{-6}, sliding displacements between crack faces are so small in the majority of cracks that friction does not adequately describe the interaction. As strain increases above 10^{-6}, frictional sliding begins to occur at more and more cracks and attenuation increases.

After eliminating friction as a loss mechanism at low strains, we still have to account for the observed energy loss at low strain amplitudes in 'dry' rock. We must also explain the change in attenuation that occurs as cracks are closed under confining pressure[3,22,23] or created through thermal cracking[3] or dilatancy[11]. Unfortunately, we do not know yet what mechanism is responsible for these losses. The data collected by Tittmann *et al.*[9] showing the strong effect that trace amounts of volatiles have on attenuation probably has a direct bearing on this mechanism. Another possibility is some form of grain boundary relaxation[26,27] or a dislocation mechanism similar to those discussed by Mason[8,28]. Whatever the cause may be, it is reasonably certain that the mechanism does not involve any macroscopic concept of friction.

Conclusion

On both experimental and theoretical grounds it seems clear that frictional energy losses occur in rock at room pressure only at strains greater than approximately 10^{-6}. This is far greater than strain amplitudes generally encountered in seismology except in regions near seismic sources. Even there the effect of confining pressure will virtually eliminate frictional energy losses in the Earth. Consequently, frictional losses are not important in seismology.

The mechanism by which cracks influence attenuation at low strains in 'dry' rock needs to be re-examined. The concept of frictional energy loss is so firmly established (on intuitive grounds) that the term 'internal friction' is often interpreted literally to mean a frictional energy loss. Though the choice of words is unfortunate, internal friction is simply a general term for energy absorption and does not imply any particular mechanism. It must be kept in mind that actual frictional energy loss is a large-strain, low-pressure phenomenon that is often observed in the laboratory, but seldom observed in the Earth.

We thank Drs Gary Mavko and Einar Kjartansson for useful discussions, Peter Gordon for assistance in constructing equipment and Lori Dengler for SEM photographs. This research was supported in part by a grant from the NSF Division of Earth Sciences (EAR 76-22501).

Radiation-induced chromosome aberrations in nuclear-dockyard workers

H. J. Evans, K. E. Buckton, G. E. Hamilton & A. Carothers

Medical Research Council, Clinical and Population Cytogenetics Unit, Western General Hospital, Edinburgh, UK

The incidence of chromosome aberrations in peripheral blood lymphocytes of 197 dockyard workers has been followed over a 10-yr period. These workers were exposed to mixed neutron-γ radiation during the refuelling of nuclear reactors, but most exposures were below the internationally accepted maximum permissible level of 5 rem per yr. There was a significant increase in chromosome damage with increasing exposure; aberration frequency was a linear function of dose and was influenced by age and time of blood sampling after exposure.

CYTOGENETIC studies on human peripheral blood lymphocytes exposed to low doses of ionising radiation *in vitro* have shown that it is possible to detect significant levels of chromosome damage from the analysis of a few hundred cells. For example[1], the frequency of dicentric and ring aberrations in nonirradiated control blood cells was found to be 1 in 10^3 and this increased approximately 20-fold after *in vitro* exposure to 30 rad of X rays, the incidence increasing linearly over the range 0–50 rad with no evidence for a threshold dose level. At higher exposure levels, the contribution of a 'dose-squared' component becomes more significant, so that over higher ranges of exposure the yields of such aberrations may approximate to the square of dose. In contrast, the aberration frequency after *in vitro* exposure of blood cells to high linear energy transfer radiations, such as 0.7–0.9 MeV fission neutrons[2–4], increases linearly over a wide dose range and such radiations are considerably more efficient than X rays, per unit of absorbed dose, at dose levels over a range (below a few hundred rad) yielding less than an average of one dicentric aberration per cell.

0028–0836/79/0277—0531$01.00

Studies on chromosomes of lymphocytes from people exposed to ionising radiation have also revealed increased aberration yields after *in vivo* exposure to relatively low doses of X rays, γ rays or fast neutrons. Moreover, because of the equivalent sensitivity of lymphocyte chromosomes to radiation damage *in vitro* and *in vivo*[5], and because of the strict relationship between aberration frequency and radiation dose and quality *in vitro*, it has become standard practice to use lymphocyte aberration frequencies as a 'biological dosimeter' in cases of accidental *in vivo* exposure to radiation[6,7]. Extrapolation from *in vitro* studies suggests that an acute X-ray exposure of 5 rad (equal to the maximum permitted annual dose for a radiation worker) would increase the spontaneous frequency of dicentric aberrations by a factor of three or four, so that the 'doubling dose' for these somatic genetic effects is quite small. However, there is little direct information on the possible effects of low dose *in vivo* exposures. A study of workers employed at a UK Atomic Energy Establishment showed that those occupationally exposed to mixed neutron-γ radiation, at levels below the maximum permissible exposure levels, had a significant excess of blood lymphocytes containing dicentric or ring aberrations relative to on-site controls[8]. However, no quantitative dose-effect relationship was evident, possibly because of inadequacy of the control data, a varying pattern of dose accumulation with time between individuals receiving similar total doses, too small a number of subjects or too few cells scored.

The population and methods of analysis

In 1968 the opening locally of an establishment for servicing and refuelling nuclear powered submarines provided an opportunity for studying a population of men subject to occupational radiation exposure within the maximum permissible limits of 5 rem per yr. As the majority of the workers at the new establishment had not received previous occupational exposure to radiation, blood samples were taken before their classification as 'radiation workers', to give background control samples, and serial blood samples were later obtained as dose was accumulated. This population has now been studied over a 10-yr period and chromosome aberrations scored in blood lymphocytes of 197 men, the majority of whom have been sampled on several occasions.

A heparinised venous blood sample of 5 ml was taken at the time of a workers 'preclassification' examination, or annual medical check up, and set up in culture later on the same day. Blood culture and chromosome preparation techniques were those that have been standard in this laboratory[9] throughout the study period, with all cultures incubated for 48 h at 37 °C. Preparations were stained with orcein and for each culture 100 cells with 45 or more centromeres were scored directly under the microscope by one observer for dicentrics, rings, acentric fragments, minutes, abnormal monocentrics, additional or absent monocentrics (aneuploidy), a medium-sized chromosome with abnormal centromere separation (almost certainly an abnormal X chromosome[10,11]) and chromatid aberrations, although not all these abnormalities would be expected to be consequences of radiation exposure (see below). All blood samples were coded and the cytological observer had no knowledge of the radiation history of any sample at the time of scoring.

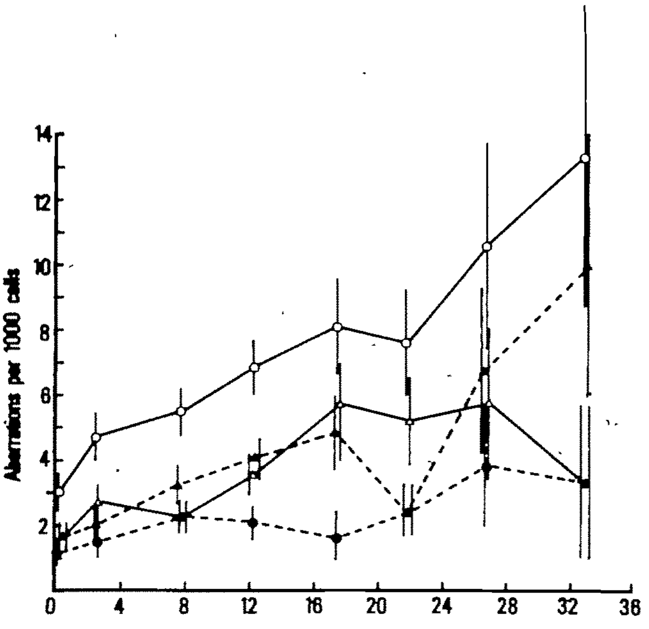

Fig. 1 Relationship between accumulated dose (rem) and mean aberration frequencies (±s.e.m.) for dicentrics (△), acentric fragments (▲), and for Cu (○) and Cs (●) cells.

Dose estimates (in rems) from film badges were provided by the Admiralty Radiation Records Centre, Institute of Naval Medicine, and were obtained independently of the receipt of blood samples and some time after completion of chromosome analyses. The radiation sources were nuclear submarine reactors undergoing refit and emitting mixed neutron-γ radiation, but the exposures were stated to involve 'almost exclusively gamma radiation'.

The data obtained over the 10-yr period were grouped by cumulative dose into 5-rem intervals and the basic data from the study are presented in Table 1 and Fig. 1. From Fig. 1 it seems that the incidence of cells containing all types of structural chromosome aberrations is positively correlated with dose. However, we have evidence from studies on a variety of populations for an increase in the spontaneous frequency of aberrations—in the absence of known radiation exposure—with increasing age (unpublished data and see also ref. 12). Also, by

Table 1 Frequencies of chromosome abnormalities in the various exposure groups

the very nature of the dose accumulation process, it is to be expected that older workers and samples from later years would contribute disproportionately to the higher dose categories. The positive correlation between dose and age, and dose and year of culture, and aberration frequency is shown in Fig. 2 and it is clearly necessary to take account of the influence of these two factors in examining for correlations between level of exposure and aberration yield. For this reason the data were initially analysed by multiple linear regression under the assumption that n_i, the number of aberrations in the i-th culture, is Poisson-distributed with mean μ_i given by

$$\mu_i = N_i(a + bx_i + cy_i + dz_i)$$

where N_i = number of cells examined in i-th culture; x_i = cumulative dose received by the blood donor at the time of the i-th culture; y_i = age of donor at the time of culture; and z_i = year in which sample for the i-th culture was taken. We accept the conventional assumption of a Poisson distribution, but note that the small numbers of aberrations give insufficient data for a rigorous test of this premise. The parameters were estimated by maximising the likelihood, the significance of an effect being judged by standard likelihood-ratio tests. In this way a 'best linear model' containing only the significant ($P \leqslant 0.05$) effects was found for each type of aberration. Those aberrations whose 'best linear model' included a dose effect were then further analysed in terms of: (1) a model with a term x_i^2 to see whether significant second-order effects of dose were present; (2) a model with a term x_iy_i added to see whether a significant age–dose interaction was present.

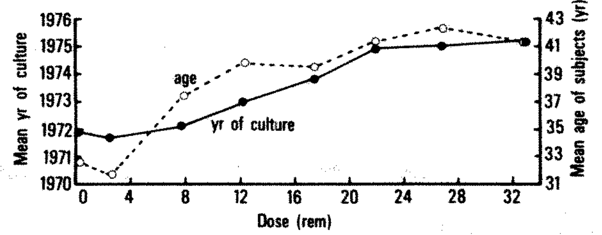

Fig. 2 The relationships between accumulated dose (rem) and year of culture (●), and dose and age of blood donor (○).

Studies on radiotherapy patients and on individuals accidentally exposed to high doses of radiation have shown that the frequency of unstable aberrations in peripheral blood lymphocytes, such as dicentrics, rings and fragments, decreases in the months and years following exposure[13]. Thus, for a given time of blood sampling, an exposure a few days or weeks before sampling results in a higher detected incidence of induced unstable aberrations than an equivalent exposure received a year or more before sampling. For this reason a third model with terms $b_1x_{1i} + b_2x_{2i}$ replacing bx_i in the best linear model was also considered, where x_{1i} = cumulative dose received before the beginning of the second full calendar year preceding the date of culture, and $x_{2i} = x_i - x_{1i}$ = the dose received since that time. The aim of this third approach was therefore to establish whether the frequency of a given aberration type showed a stronger dependence on the dose received recently (x_{2i}) than on that received earlier (x_{1i}), as would be expected if there were a genuine dose–effect causal relationship.

Dependence of aberration incidence on dose, age and time of exposure

These analyses to take into account the contribution of age and date of culture revealed significant effects of dose for the incidence of dicentric aberrations, acentric fragments and cells with such unstable aberrations (Cu cells), but not for cells with symmetrical rearrangements (Cs cells); these data are summarised in Table 2. *In vitro* radiation 'model' experiments and 'high dose' *in vivo* studies have clearly shown that the incidence of dicentric (±ring) aberrations, acentric fragments and total cells with such unstable aberrations (Cu cells) is dose dependent and that these aberrations are typical radiation-induced changes: the difficulty of detecting symmetrical rearrangements contributes to the much lower incidence of Cs relative to Cu cells and to the diminished dose dependence of Cs cell types. In contrast, as most peripheral blood lymphocytes are in a G1 phase when exposed to radiation, the majority of chromatid-type aberrations observed in such cells are not radiation-induced and these aberrations, and the incidence of aneuploidy in first post-irradiation mitoses, show little dependence on dose. Similarly, the incidence of a medium-sized chromosome with abnormally separated chromatids is independent of radiation exposure, but is heavily dependent on age and sex, being prevalent in ageing females and identified as an X chromosome[10,11]. In the present data a significant age–effect relationship, but no dose–effect relationship, was found for aneuploid cells, for chromatid aberrations and for 'X chromosomes' with abnormal centromere separation, so that these results are as expected.

The above analyses suggest that the asymmetrical, or unstable, aberrations observed in the blood cells of these dockyard workers are a consequence of their exposure to radiation. Detailed analysis of these aberrations further reveals that: (1) there are no detectable second-order effects of dose—all data are consistent with a linear dose response; (2) in all categories there is a positive age–dose interaction (Table 3), indicating a greater susceptibility to radiation-induced chromosome damage with increasing age—as suggested by earlier *in vitro* studies[14,15]; this was statistically significant ($P < 0.05$) for dicentric aberrations; and (3) for all categories the dependence on 'recent' dose is greater than on 'early' dose, although in no case do the coefficients b_1 and b_2 differ significantly (Table 2).

Implications of the findings

The demonstration of a significant dose-dependent increase in chromosome aberrations in peripheral blood leukocyte chromosomes in a population of closely monitored nuclear-dockyard workers, subject to occupational radiation exposure

Table 3 Age–dose interactions for aberrations with a significant dose-dependence

	Significance level of interaction effect	Estimated increase in incidence per rem per cell ($\times 10^4$)		
		Age 25 yr	Age 40 yr	Age 55 yr
Acentric elelements	$P = 0.24$	1.04(±0.59)	1.64(±0.40)	2.25(±0.71)
Dicentrics	$P = 0.030$	0.53(±0.59)	1.57(±0.38)	2.60(±0.68)
Acentric elements, dicentrics and rings combined	$P = 0.021$	1.57(±0.85)	3.27(±0.57)	4.97(±0.99)

within the maximum permissible level of 5 rem per yr, raises a number of questions. We should perhaps first note that the estimated rate of increase of dicentric aberrations with dose (1.4×10^{-4} dicentrics per cell per rem) is of a similar order to that obtained from our earlier data[8] on a population of occupationally exposed personnel at UKAEA Windscale, although the number of cells examined in the Windscale study was insufficient to establish significance. In this context it should be noted that the effect of increasing dose is not seen in successive cultures from the same individual, at the exposure levels encountered by our population, because the number of cells examined per individual is insufficient. For example, in these conditions of exposure, the detection of the estimated effect of 10 rem on the incidence of dicentrics in a single individual would necessitate examining of the order of 10,000 cells—a formidable task.

The yield of dicentric aberrations, or of acentric fragments, in cells from individuals obtained before occupational exposure, or after exposure to <1 rem, was ~ 1 in 700 cells, rising approximately fourfold after accumulation of doses of 20 to 30 rem. The observed increase is therefore not large, but it is a direct expression of increased genetic damage caused by radiation exposure. The dicentric aberrations observed are frequently cell lethal, as also are a proportion of the free fragments, but some of the cells containing acentric fragments, and those with symmetrical rearrangements such as translocations, are viable and a proportion of these are detected as Cs cells. Cs cells are not easily distinguished, represent ~ 1 in 900 cells studied in individuals receiving <1 rem, and are approximately three times as frequent in individuals who accumulated more than 25 rem. It is not clear whether there is a somatic effect on the individual as a result of the presence of Cs cells, although each such cell presumably contains some kind of mutational change and there are many thousands of such cells present in blood lymphocytes and bone-marrow cells of individuals not exposed to radiation. Our data therefore tell us nothing about possible biological consequences, but merely demonstrate that it is possible to detect a biological effect at the chromosome level of occupational exposure to ionising radiation below the internationally agreed maximum permissible levels.

There has been much recent publicity concerning possible increased cancer incidence—particularly leukaemias and lymphomas—in occupationally exposed personnel in the USA in a Naval dockyard[16,17] and in the atomic energy plant at Hanford[18,19]. However, the data on which some of these claims have been based, and the analyses involved, have been very heavily criticised[20–23]. It is therefore pertinent for us to point out that the exposed population that we have studied is small, subject to very low levels of radiation exposure for periods up to only 10 yr—and is therefore unlikely to provide useful data on the incidence of malignant disease. During the 10-yr study there were 2 deaths amongst the 197 men studied, both due to myocardial infarction: there was no record of deaths due to leukaemia or other malignant disease. Examination of the Registrar General's returns for deaths attributed to, or associated with, leukaemias for the area which includes our naval dockyard, has revealed no increase in the incidence of leukaemia relative to other populations over the years 1967–77, and no disproportionate number of dockyard workers suffering such deaths. We emphasise again, however, that the population size is small and it would seem sensible to monitor causes of death in a larger population of workers exposed to radiations within the occupational limits—a project that has already been initiated by the National Radiological Protection Board[24].

We thank the workers at HM Naval Base Rosyth for their cooperation, the Senior Medical Officers and staff at Rosyth and Head of NRPS and staff at Alverstoke for providing blood samples and dose records, and D. G. Papworth for statistical advice.

Selective activation of human β- but not γ-globin gene in human fibroblast × mouse erythroleukaemia cell hybrids

Marcia C. Willing, Arthur W. Nienhuis & W. French Anderson

Laboratory of Molecular Hematology, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, Maryland 20014

The human α- and β-globin genes have been activated in MEL × human fibroblast cell hybrids. However, even though the human γ- and β-globin genes are closely linked and were shown in these hybrid clones to be present in approximately equal numbers, no human γ-globin mRNA was produced. Thus, the human β- and γ-globin genes in these cells are differentially regulated apparently by a positive regulatory factor(s) specific for individual globin genes.

IN order to define the mechanism of globin gene regulation in mammalian cells, we have examined the expression of the mouse and human haemoglobin genes in somatic cell hybrids between mouse erythroleukaemia (MEL) cells and various human cell lines[1–6]. Previous studies have shown that fusions between MEL cells and human (or Chinese hamster) erythroid cells resulted in co-expression of mouse and human (or Chinese hamster) haemoglobin[1,2]; fusions of MEL cells with non-erythroid cells resulted in hybrids which could not be induced to make haemoglobin[3,4,7–10], even though the globin genes were present in the hybrid cells[3]. Gopalakrishnan *et al.*[4] obtained evidence for the existence, in the cytoplasm of non-erythroid cells, of a

2S MEL is an MEL cell line containing a sub-tetraploid complement of chromosomes[5]; it is TK$^-$. HLN stands for a human Lesch-Nyhan skin fibroblast primary cell line (CRL 1112, ATCC), and is HGPRT$^-$. XVIII-5 is the 5th clone of the 18th fusion of 2S MEL cells to human non-erythroid cells. For the chromosome analysis: approximately 10^7 cells were washed in Dulbecco's phosphate-buffered saline, swollen in 0.075 M KCl, fixed in 3 : 1 methanol–acetic acid and dropped onto glass slides. Photographs of at least 15 metaphase spreads per clone were counted to estimate the total number of chromosomes and per cent of metacentric chromosomes. The spreads were made from an aliquot of the same expanded and induced cell population from which the isozyme analyses were done and from which the RNA and DNA were isolated for the studies in Table 2 and Figures 2–4. For the isozyme analysis: human chromosome 11 is known to have LDH-A and the γ-δ-β globin gene complex[20]; human chromosome 16 is known to have APRT and human α-globin[19]; LDH-B is on human chromosome 12. APRT analyses were by the method of Tischfield *et al.*[30]. Only hybrids positive for human LDH-A (chromosome 11) are shown; approximately 25% of the successful fusions between 2S MEL and HLN cells resulted in retention of chromosome 11 after expansion. M, mouse; H-A, human LDH-A; H-B, human LDH-B; H, human. The scale is: 0, None detectable; ± → +++ = increasingly positive.

negative regulatory factor which prevented the subsequent induction of haemoglobin in MEL 'cybrids' obtained by fusion of intact MEL cells with enucleated non-erythroid cells. Recently, Deisseroth and Hendrick[11] showed that human α-globin mRNA as well as mouse globin mRNA was expressed in 1S MEL × human erythroid cell hybrids when human chromosome 16 had been selectively retained. It is not known if a fibroblast α-globin gene would have been activated in these 1S MEL hybrids.

We wish to learn if erythroid cells (such as MEL cells) might contain one or more positive regulatory factors. Evidence for positive regulation would exist if conditions could be found that result in activation of fibroblast globin genes (as well as MEL globin genes) in MEL × fibroblast hybrids. A gene dosage effect has been used by others to obtain phenotypic expression of differentiated functions in somatic cell hybrids[12–17]; an increased input of chromosomes from one parental cell can yield hybrid cells in which a previously unexpressed function might be activated[17,18]. Weiss and coworkers[17] have extensively studied the activation of albumin synthesis and other liver functions in rat hepatoma × mouse lymphoid cell hybrids. The expression of rat hepatic functions, and the activation of such functions from the mouse lymphoid chromosomes, was greatly increased by the use of a 2S (tetraploid) hepatoma parental cell[17]. Our laboratory developed a stable 2S (tetraploid) MEL cell line[5] and demonstrated that 2S MEL × fibroblast hybrids were inducible for haemoglobin as shown by positive benzidine staining of hybrid cell clones. It was also demonstrated that 1S MEL × fibroblast fusions can result in haemoglobin inducible hybrids although the efficiency is greatly increased when 2S MEL cells are used.

We have now tested for the expression of mouse and human globin genes by measuring the amounts of mouse and human globin mRNA in somatic cell hybrids derived from fusions of 2S MEL cells with human fibroblasts. The human α-globin gene is on chromosome 16 (ref. 19) and the human γ-δ-β globin gene locus is on chromosome 11 (ref. 20). Adults synthesise primarily haemoglobin A ($\alpha_2\beta_2$) while the human fetus synthesises primarily haemoglobin F ($\alpha_2\gamma_2$). Soon after birth, haemoglobin F is replaced by haemoglobin A. Since the γ- and β-globin genes are closely linked, our experimental model is unique in that it provides the opportunity to examine the expression of two closely linked genes at the molecular (mRNA) level. Our results indicate that, when human chromosome 16 is present in the hybrid clone, human α-globin mRNA is produced (in addition to mouse globin mRNA); when chromosome 11 is present, human β-globin mRNA is found. Surprisingly, however, even when human β-globin mRNA is present in large amounts, no human γ-globin mRNA is detectable. Thus, even though the β- and γ-globin genes are closely linked and were shown to be present in approximately equal numbers in these hybrid cells, only the β-globin gene is expressed. Thus, the mechanism of differential regulation of human β- and γ-globin genes seems to involve, at least in these cells, a globin gene specific regulatory factor(s).

Hybrids between MEL cells and human fibroblasts

Fusions were performed between thymidine kinase deficient (TK$^-$) 2S MEL cells[5] and various hypoxanthine-guanine-phosphoribosyl-transferase deficient (HGPRT$^-$) human non-erythroid cell lines. In each fusion, several individual clones were grown to 10^6 cells and analysed for human lactate dehydrogenase-A (LDH-A); human chromosome 11 contains LDH-A and the γ-δ-β globin gene complex. Positive clones were expanded to 5×10^8 cells and a repeat isozyme analysis carried out. If the clone was still positive for LDH-A, a portion of the

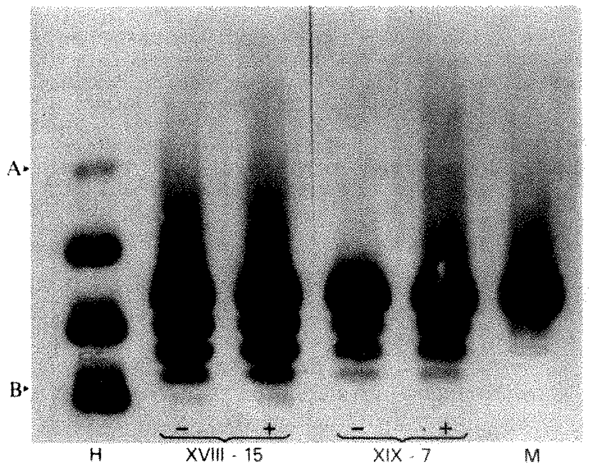

Fig. 1 Lactate dehydrogenase (LDH) isozyme pattern of the parental 2S MEL cells, human Lesch-Nyhan (HLN) skin fibroblast primary cells, and two of the hybrids between them. The parental lines, 2S MEL and human Lesch-Nyhan fibroblasts (see Table 1), were grown in F14 medium (available without $NaHCO_3$ from Gibco as F12-modified medium 72004) supplemented with 3.7 gl^{-1} $NaHCO_3$ and with 10% fetal calf serum[31]. 2S MEL cells (1×10^7) were mixed with 1×10^6 trypsinised HLN fibroblasts, washed twice in serum-free medium, resuspended in 1 ml of serum-free medium containing 250 HAU of inactivated Sendai virus, incubated at 0 °C for 15 min, then at 37 °C for 1 h, resuspended at 5×10^4 cells ml^{-1} in medium with serum, and incubated at 37 °C in 10% CO_2 at 100% humidity[5]. The next day cells were plated in 0.1 ml in microtiter wells (Falcon) at different dilutions. After 24 h, 0.1 ml of medium containing 2 × HAT was added to each well. After 2–3 weeks, wells containing visible colonies (all floating cells) were transferred to 60-mm dishes in medium containing 10^{-4} M hypoxanthine and 1.6×10^{-5} M thymidine. After 1 week in this medium, the cells were transferred to regular growth medium (F14 plus 10% fetal calf serum) and expanded to 1×10^6 cells. Each clone was then analysed for human LDH-A. Electrophoresis was carried out using the Gelman LDH isozyme electrophoresis system (according to Technical Bulletin 23) with Corning ACI agarose electrophoresis film. Positive clones were grown to $3\text{–}5 \times 10^8$ cells and re-checked for LDH-A. One-half the culture was transferred to medium containing 2.0% DMSO and incubated for 5–6 days (reaching approximately 10^9 cells); the remaining half was continued in regular growth medium for 2–4 days to reach 10^9 cells. Aliquots from each incubation were taken for LDH and APRT isozyme electrophoresis, chromosome analysis, benzidine reactivity and ^{3}H-leucine incorporation into globin chains. All remaining cells were used for RNA and DNA extraction as described in the legend to Fig. 2. H, human Lesch-Nyhan fibroblasts; M, 2S MEL cells; XVIII-15 and XIX-7 are hybrids; –, means after expansion to 10^9 cells but without induction; +, means after expansion and induction of haemoglobin by 5–6 days growth in 2% dimethylsulfoxide. Fig. 2 Hybridisation of hybrid cell RNA to ^{3}H-mouse globin cDNA and ^{32}P-human α-globin cDNA. Hybrid cells (see Fig. 1 legend) were pelleted, washed once in minimal essential medium, repelleted, and then suspended in a solution of 10 mM Tris-HCl, *p*H 8, 2 mM $MgCl_2$, 3 mM $CaCl_2$, 0.1% Triton X-100, 0.5 mM dithiothreitol, and 0.1 M sucrose. Nuclei were obtained by homogenisation with a motor driven Teflon-glass Dounce homogeniser (4–6 strokes at full speed); the nuclear suspension was diluted 1 : 1 in an identical buffer but with a sucrose concentration of 0.25 M. 20 ml of the nuclei suspension was then layered onto 10 ml of a 0.33 M sucrose cushion containing 10 mM Tris-HCl, *p*H 8, 5 mM $MgCl_2$, and 0.5 mM dithiothreitol. The nuclei were pelleted by centrifugation at 800 *g* (2,200 r.p.m. in a GLC tabletop centrifuge) for 5–10 min. The supernatant fraction was removed for RNA extraction; DNA was extracted from the nuclear pellet as previously described[26]. For RNA extraction, the supernatant from the preparation of nuclei was made 0.1 M in NaOAc (*p*H 5) and 10 mM EDTA. Subsequent phenol extraction at 55 °C, ethanol precipitation, DNase treatment, re-extraction with phenol, and passage over a G-50 Sephadex column was as described previously[32,33]. Mouse globin cDNA was prepared as previously described[34] using mouse reticulocyte mRNA prepared from polysomes[32] as a template for RNA-directed DNA polymerase. ^{3}H-CTP was used as the label yielding a probe with a specific activity of 10,000–12,000 c.p.m. μg^{-1}. A size fraction 500–600 nucleotides in length was selected by alkaline sucrose gradient centrifugation[34]. Plasmid DNA (100–150 μg) from JW 101 (human α), JW 102 (human β), or JW 151 (human γ)[21] was digested with *Mbo*II (JW 101) or *Hha*I (JW 102, JW 151) and the resulting DNA fragments were fractionated on a sucrose gradient (5–20%) in 10 mM Tris-HCl, *p*H 7.5, 100 mM NaCl, and 1 mM EDTA[35]. The largest fragment, which contains the globin gene insert, was recovered by ethanol precipitation. Nick-translation[36,37] in the presence of ^{32}P-dCTP resulted in a specific activity of approximately 10^8 c.p.m. μg^{-1}. Each plasmid fragment was annealed in 50% formamide, 0.5 M NaCl to homologous mRNA (that is, the fragment containing either the α- or β-globin gene was annealed to human adult globin mRNA (α and β) while the *Hha*I fragment containing the γ-globin gene was annealed to fetal reticulocyte mRNA (α, β, and γ)) at 66.5 °C. At this temperature DNA will not reanneal, but a duplex between mRNA and the cDNA strand of the insert is formed. Digestion with S_1 nuclease resulted in destruction of all DNA except that in a duplex. The single-stranded cDNA fragment was then recovered by alkaline sucrose gradient centrifugation[35] and used for mRNA · cDNA (and DNA · cDNA) hybridisations. mRNA · cDNA hybridisation was carried out as previously described[34] except that both ^{3}H-mouse globin cDNA and ^{32}P-human α-globin cDNA were used in each double labelled reaction. Titrations were performed in 50% formamide, 0.5 M NaCl at 66.5 °C. Incubation to achieve equilibrium was for 48 h after which duplex formation was analysed by S_1 nuclease resistance[33]. Each 10 μl reaction mixture contained 2,000 c.p.m. of ^{3}H-mouse globin cDNA and 2,000 c.p.m. of ^{32}P-human α-globin probe. Control incubations showed: (1) duplex formation resulting from titration with mouse reticulocyte mRNA reached 82% for the ^{3}H-mouse cDNA, but less than 1% for the ^{32}P-human α cDNA; and (2), duplex formation resulting from titration with human reticulocyte mRNA reached 71% for the ^{32}P-human α cDNA but less than 1% for the ^{3}H-mouse cDNA. Values were normalised by dividing each ^{3}H value by 0.82 and each ^{32}P value by 0.71. The ^{3}H values for all six hybrids were similar and were, therefore, averaged. Similar computations were performed for the data in Figs 3 and 4. ●, Hybridisation with ^{3}H-mouse globin cDNA (the values for all six hybrid cell RNAs have been averaged and normalized; see above); □, hybridisation of the RNA from hybrid XIX-2 with ^{32}P-human α-globin cDNA; △, RNA from XIX-10 with ^{32}P-human α-globin cDNA; ○, RNA from XVIII-5, XVIII-15, XIX-7, and XX-8 with ^{32}P-human α-globin cDNA.

cells were grown in 2% dimethylsulphoxide (DMSO) for 5–6 days and the remainder for a shorter period without inducer (see Fig. 1 legend). Aliquots from each incubation were taken for isozyme analysis, karyology, haemoglobin inducibility and ^{3}H-leucine incorporation into globin chains. RNA and DNA were then extracted from the remaining cells as described in Fig. 2 legend.

The phenotypic characteristics of the 2S MEL and the human Lesch-Nyhan (HLN) skin fibroblast primary parents, as well as of six hybrids between them, are shown in Table 1. Only the six hybrids which are positive for LDH-A (Fig. 1) are shown, since β-globin mRNA was not found in the hybrid clones lacking LDH-A (data not shown). APRT was examined as it is a marker for chromosome 16 which carries the human α-globin gene. Chromosome analysis shows that the hybrids possess an increased number of chromosomes and a higher percentage of metacentrics than the 2S MEL parent. All six were positive for mouse LDH, mouse APRT, and human LDH-A; three were positive for LDH-B (carried on chromosome 12); two for human APRT. XIX-2, the hybrid with the highest number of chromosomes (122 with 22% metacentrics), was the only clone positive for all three human enzymes: LDH-A, LDH-B, and APRT. As shown in Table 2, all six hybrids could be induced to make haemoglobin as determined by benzidine staining.

Detection of human globin mRNA in cell hybrids

Pure single stranded probes complementary to human α-, β-, or γ-globin mRNA were prepared from recombinant cDNA plasmid clones JW 101, 102, or 151 (ref. 21), respectively, as described in Fig. 2 legend. The cytoplasmic RNA from each hybrid line was separately hybridised to each ^{32}P-labelled human probe in the presence of ^{3}H-labelled mouse globin cDNA. In the data in Figs 2–4, the ^{3}H-mouse globin cDNA hybridisation values for all six hybrid cell RNAs were averaged (solid circles), and all points were normalised, as described in Fig. 2 legend. Thus, the plots of α, β, and γ human globin mRNA for each of the six hybrids can be compared to each other.

As shown in Fig. 2, two hybrids contain small amounts of human α-globin mRNA: XIX-2 and XIX-10. Both these hybrids were positive for human APRT on enzyme analysis (Table 1). Five of the six hybrids positive for human LDH-A had clearly detectable human β-globin mRNA (Fig. 3). XX-8, the hybrid with the highest concentration of human β-globin mRNA and a strong LDH-A band, had 35% as many human β-globin mRNA sequences as mouse globin mRNA sequences. There is a fairly close correlation between the amount of LDH-A in a given hybrid cell line (Table 1) and the amount of human β-globin mRNA present (Fig. 3, Table 2).

None of the hybrids had detectable human γ-globin mRNA sequences, even at 60 μg RNA input (Fig. 4). When the human γ-globin cDNA probe was annealed to mRNA isolated from fetal cord blood in a simultaneous experiment, 72% of the γ probe was incorporated into duplexes; a saturation plateau was achieved above an input of 5 ng of partially purified mRNA (data not shown). As expected, since the γ- and β-globin genes are closely linked, DNA·cDNA hybridisation demonstrated approximately equal concentrations of γ- and β-globin gene sequences in the hybrid cell DNA (data not shown). Analysis of the RNA from the expanded but uninduced hybrid cell showed very low levels of mouse globin mRNA, no (or barely detectable) human β-globin mRNA, and no detectable human γ-globin mRNA.

Carboxymethylcellulose chromatography of the ^{3}H-leucine globin chains synthesised by the hybrids positive for human β-globin mRNA revealed a peak in the region of human β-globin. However, the calculated number of globin chains in the

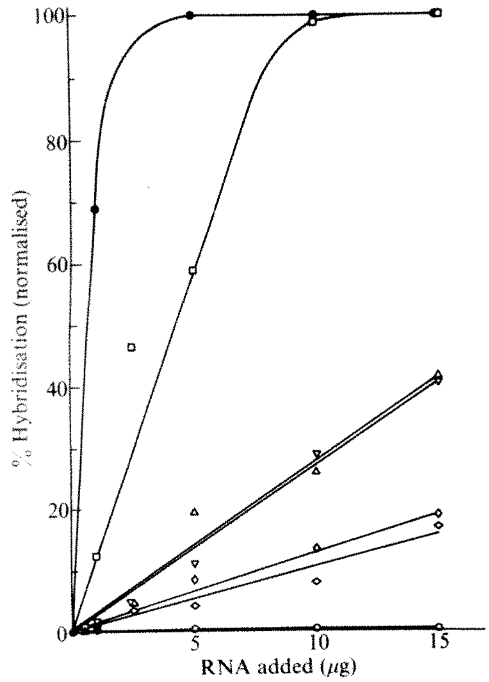

Fig. 3 Hybridisation of hybrid cell RNA to ^{3}H-mouse globin cDNA and ^{32}P-human β-globin cDNA. Experimental conditions were as for Fig. 2 except that human β-globin cDNA from the cDNA plasmid JW 102[21] was used. Hybridisation of the β-globin probe to globin mRNA obtained from adult human reticulocytes reached a plateau of 78.5%. All hybrid RNA points with ^{32}P-human β cDNA were divided by 0.785 to normalise them to a maximum of 100%. ●, Average value for hybrid cell RNA with ^{3}H-mouse globin cDNA; open symbols are for hybrid cell RNA with ^{32}P-human β-globin cDNA; □, XX-8; △, XIX-7, ▽, XVIII-15; ◇, XIX-2; ◇, XVIII-5; ○, XIX-10.

human β-globin region did not correlate with the concentration of human β-globin mRNA molecules known to be present. Further analysis of the putative human β-globin is underway.

Discussion

In this study, we have shown that the globin genes of human fibroblasts can be activated in fibroblast × 2S MEL cell hybrids. The expression of fibroblast globin genes implies the presence in the induced 2S MEL hybrid cells of a positive regulatory factor of some type. While the adult human globin genes, α and β, were consistently activated when the human chromosomes bearing these genes were present in the hybrid clones (chromosome 16 for α, chromosome 11 for β), the human γ-globin gene, which is closely linked with β-globin, was not expressed at all. Thus, in these cells, there is a differential regulation within the γ-β globin gene locus.

Several mechanisms might account for such differential gene regulation. First, a diffusable regulatory factor could act as a positive activator of the human β- but not γ-globin gene by binding to a controlling region adjacent to the globin gene structural sequences. Many examples of such regulatory factors in prokaryotes have been described[22]. A single factor might be responsible for activating the human α, human β, and the mouse globin genes, or several different globin gene specific factors could be involved.

A second possible mechanism which could account for differential globin gene activation in these hybrid cells would be the state of the parental cell's chromatin before and after fusion. Expression of a gene requires that its sequences be in an active conformation in nuclear chromatin. Exposure of nuclei to pancreatic DNase I results in selective digestion of active genes[23–26]. Thus, in erythroid cells, the globin genes are DNase I sensitive while in fibroblasts the globin genes are resistant. We assume that the human β- and α-globin genes were resistant in the parental fibroblasts but were converted to the active conformation in the hybrid clones. It is thought that non-histone proteins may be operative in initiating and propagating the active conformation of nucleosomes associated with expressed genes. If so, these 'regulatory factors' for mouse MEL cells would act on both mouse and human α- and β-globin genes, but possibly not on the human γ-globin gene. Since adult human fibroblasts were used in this study, it is possible that, if chromatin structure of the parental cells is important, a fusion of 2S MEL cells with fetal fibroblasts would result in expression of human γ-globin mRNA. To test this hypothesis, hybrids were formed between 2S MEL and fetal amniotic cells and are now being analysed for β- and γ-globin mRNA synthesis.

Table 2 Haemoglobin inducibility of 2S MEL × HLN hybrids and parents

Cell line	Haemoglobin inducible (%)	Mouse globin mRNA	Human globin mRNA α	β	γ
Parents					
2S MEL	60	+++	0	0	0
HLN	0	0	0	0	0
Hybrids					
XVIII-5	85	+++	0	+	0
XVIII-15	40	+++	0	++	0
XIX-2	55	+++	++	+	0
XIX-7	85	+++	0	++	0
XIX-10	70	+++	+	0	0
XX-8	95	+++	0	+++	0

Haemoglobin inducibility is the per cent of cells in the population which were benzidine positive after incubation for 5 days in 2% dimethylsulphoxide (DMSO). Actively growing floating cells were resuspended at a concentration of 0.5–1 × 10^5 cells/ml in F14 medium containing 10% fetal calf serum and 2% DMSO. After 5 days the cells were stained by the addition of one-tenth the volume of a fresh solution containing 0.2% (w/v) of benzidine dihydrochloride and 0.4% (v/v) H_2O_2 in 0.5 M acetic acid[1]. Mouse globin mRNA was measured by hybridisation with ^{3}H-cDNA made from unfractionated mouse reticulocyte mRNA; human α-, β- and γ-globin mRNA were measured with pure probes obtained from recombinant cDNA plasmids (see Fig. 2 legend). The scale is: 0 = none detectable; + → +++ = increasingly positive.

Another possible mechanism of differential gene expression is selective processing of globin gene transcripts. In our present

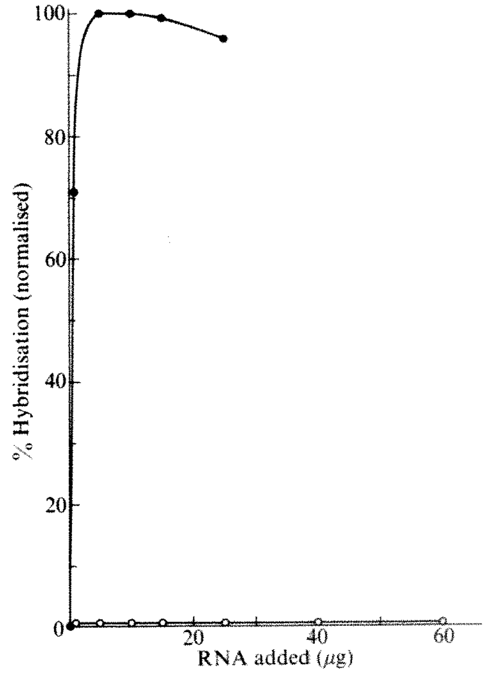

Fig. 4 Hybridisation of hybrid cell RNA to ^{3}H-mouse globin cDNA and ^{32}P-human γ-globin cDNA. Experimental conditions were as for Fig. 2, except that human γ-globin cDNA from the cDNA plasmid JW 151[21] was used. Hybridisation of the γ-globin probe to globin mRNA obtained from cord blood red cells reached a plateau of 72%. ●, Average value for hybrid cell RNA with ^{3}H-mouse globin cDNA; ○, hybrid cell RNA with ^{32}P-human γ-globin cDNA (all six were negative).

study, the hybrid cell nuclei were used for DNA extraction, and the RNA was isolated from the cytoplasm only. It is possible that human γ-globin gene sequences were present in the nuclei, but were selectively degraded or were not processed in such a way that they could reach the cytoplasm. Thus, specific and selective MEL processing enzymes could have been involved. Extraction and analysis of nuclear RNA should detect all but rapidly degraded γ-globin gene sequences.

Whether the factor(s) that controls globin gene expression acts by binding directly to a controlling region of a globin gene 'operon', at the level of chromatin structure, by influencing processing of the primary globin gene transcript, or by some other mechanism, there is no factor in the induced MEL hybrid cell that results in expression of the human γ-globin gene.

If a diffusable positive regulatory factor(s) does exist in induced MEL cells, it should be possible to isolate and characterise it. The recent availability of cloned globin genes from genomic DNA obtained by recombinant DNA technology[27,28] should allow cell-free systems to be developed to test the mechanism of action of these factors. As a preliminary to cell-free studies, we are attempting to isolate such putative factors by fractionating the induced 2S MEL cells and microinjecting the cell fractions into uninduced MEL cells to look for induction[6,29]. Preliminary results indicate that a 2S MEL cell can be induced by microinjecting 10^{-11} ml of 100 mM hexamethylene bisactamide (W. F. A. and E. Diacumakos, unpublished results). Microinjection of MEL cell fractions is now underway.

The existence of a factor specific for human β-globin implies that a similar factor might exist to control the human γ-globin gene. Such a factor might have clinical importance since the ability to express the γ-globin in β-haemoglobinopathies or in β-thalassemia could be highly beneficial. To this end, hybrids are also being made using fibroblasts from patients (and at-risk fetuses) with sickle cell anaemia and β-thalassemia to study the globin expression from fibroblasts of patients with beta chain abnormalities.

We thank Ms E. Church and Ms P. Turner for technical assistance, Dr T. V. Gopalakrishnan for useful discussions, Dr D. Vembu for carrying out the APRT analysis, Drs B. Forget, J. T. Wilson, and S. M. Weissman for the human α (JW 101), β (JW 102) and γ (JW 151) cDNA recombinant plasmids, and Mrs E. Murray for editorial assistance.

Escherichia coli mutants accumulating the precursor of a secreted protein in the cytoplasm

Philip Bassford & Jon Beckwith
Department of Microbiology and Molecular Genetics, Harvard Medical School, Boston, Massachusetts 02115

The maltose binding protein of Escherichia coli *is secreted into the external periplasmic compartment of the cell. This article describes a selection procedure for the isolation of mutants which fail to export this protein. These mutants probably result from alterations in the amino terminal 'signal sequence', causing the maltose binding protein produced to accumulate in the cytoplasm in its precursor form.*

SECRETED proteins in both bacterial and eukaryotic cells are initially synthesised as longer precursors with so-called 'signal sequences' at their amino termini, which are subsequently excised[1–6]. This signal sequence is thought to be responsible for initiating passage of the polypeptide through the membrane while it is still a nascent chain attached to the ribosome. The study of protein secretion in bacteria provides the obvious advantages of an easily-manipulated genetic system. We describe here the isolation of mutants of *Escherichia coli* in which the maltose binding protein (MBP), which is normally secreted across the cytoplasmic membrane into the periplasmic space, accumulates in the cytoplasm in its precursor form. This is most probably a result of alterations in the signal sequence. The MBP is a key component of the maltose transport system of this organism. It is a 38,000 molecular weight protein[7] which is synthesised on ribosomes attached to the cytoplasmic side of the cytoplasmic membrane[8]. As predicted by the signal hypothesis, MBP is initially synthesised with an amino-terminal extension some 20 to 30 amino acids long[9].

0028-0836/79/0277—0538$01.00

Fusions of *malE* and *lacZ* genes

To isolate mutants in the MBP (*malE* gene), we used the gene fusion technique of Casadaban[10,11] to isolate strains in which the *lacZ* gene encoding the normally cytoplasmic enzyme β-galactosidase is fused to the *malE* gene. The product of such a fusion is often a hybrid protein in which the amino terminus of β-galactosidase has been replaced with an amino-terminal MBP sequence but which retains β-galactosidase enzyme activity. The signal hypothesis predicts that such a hybrid protein would be exported to the periplasm if it includes an intact MBP signal sequence. As described below, the properties of such fusion strains permit a direct selection for signal sequence mutants.

Strain PB72-47 is a *malE–lacZ* fusion strain which synthesises a very large hybrid protein (molecular weight 131,000) including a major amino-terminal portion of the MBP (Fig. 1). This strain does not, however, export the hybrid protein to the periplasm. Instead, it is localised to the cytoplasmic membrane (Table 1), suggesting that the export process may at least have been initiated. The strain also exhibits a rather unusual phenotype. When it is induced for the synthesis of the hybrid protein by the addition of maltose to the growth medium, cell division is inhibited concomitantly with the appearance of β-galactosidase activity. The cells at this point elongate to several times their normal length. Eventually, 3 to 4 h after induction, the cells begin to lyse. This 'maltose-sensitive' phenotype is a direct consequence of the synthesis of the hybrid protein. Mutations which eliminate the synthesis of hybrid protein (such as chain-terminating nonsense mutations in the hybrid gene) restore normal growth. The maltose-sensitive phenotype of strain PB72-47 apparently results from the cell's abortive attempt to export the hybrid proteins. For some reason, the cell's export apparatus cannot accommodate these unusually large polypeptides, and they remain literally 'stuck' in the cytoplasmic membrane. This has adverse consequences for the cell, since the failure to export these hybrid proteins also interferes with the transport of other exported proteins, which accumulate within the cell in their precursor forms[12].

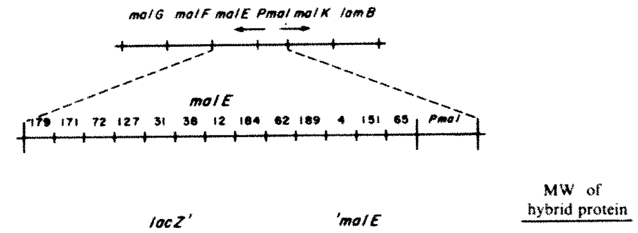

Fig. 1 The *malE* gene is one of five genes whose products are components of the maltose transport system. These are organised into two operons orientated in opposite directions and which diverge from the promotor region designated here as 'Pmal'[16]. Maltose is the inducer for both operons. A deletion map of the *malEFG* operon has been constructed. The *malE* gene has been divided into 13 segments, so identified on the basis of recombination of deletions with insertions of phage Mu DNA at different points along its length (indicated here by numbers). Using these same Mu insertions, the approximate portion of the *malE* gene included in the hybrid gene in the *malE–lacZ* fusion strains PB63–37 and PB72–47 has been established. The end point within the *lacZ* gene for both fusions is genetically identical. The genetic data agrees with the molecular weights determined for the hybrid proteins encoded by these two fusion strains. Thus, the molecular weight differences discerned between different *malE–lacZ* hybrid proteins reflect differences in the contribution of the MBP to the hybrid product. Details on the construction of the deletion map, the isolation of the *malE–lacZ* fusion strains, and a complete description of the maltose-sensitive phenotype will be presented elsewhere[18,19].

Table 1 Localisation of β-galactosidase activity in strain PB72–47 and representative Mal^R Lac$^+$ derivatives*

Strain	β-galactosidase (Units per mg protein†)	β-galactosidase activity‡ (%)			Response to maltose
		Sonicate	Soluble	Insoluble§	
PB72-47	960	100	23	74	Sensitive
PB72-47-R1	1,483	100	71	25	Resistant
PB72-47-R2	1,275	100	65	33	Resistant

* Mal^R Lac$^+$ mutants were obtained by screening for strains that could form large, blue colonies on maltose minimal agar plates containing the indicator dye 5-bromo-4-chloro-β-D-galactoside.

† All strains were grown to mid-log phase in glycerol minimal medium at 30 C and induced by the addition of 0.2% maltose for the final 180 min of culture. One unit of β-galactosidase activity is that amount of enzyme that will hydrolyse 1 nmol of *o*-nitrophenylgalactoside per min. Note that the original fusion strains themselves are Mal$^-$ due to the inactivation of the *malE* gene. To permit induction by maltose, the hybrid genes were transferred on a λ transducing phage (see Fig. 3) into a *mal*$^+$ genetic background.

‡ Cells were disrupted by sonication[11]. Enzyme activities were normalised with the activity present in the sonicate after the removal of remaining whole cells and are expressed as a percentage of such. Soluble and insoluble refer to the supernatant and pellet, respectively, after centrifugation at 100,000 *g* for 1 h.

§ In a separate experiment, the cytoplasmic and outer membranes were separated according to the method of Osborn *et al.*[17]. >90% of the membrane-associated enzyme activity fractionated with the cytoplasmic membrane.

Selection for export-defective mutants

If the attempt by the cell to export these hybrid proteins is responsible for the maltose-sensitive phenotype, then mutants resistant to maltose should include ones defective in export. Spontaneous mutant derivatives of strain PB72-47 were selected which continue to synthesise the hybrid protein but which are maltose-resistant (Mal^R). Since the most frequent cause of the Mal^R phenotype are mutations eliminating synthesis of the hybrid protein (Mal^R Lac$^-$), only those derivatives which were Mal^R Lac$^+$ were analysed. It was reasoned that such Mal^R Lac$^+$ mutants would no longer attempt to export the protein but, rather, the protein would remain in the cytoplasm. This was so for all the Mal^R Lac$^+$ strains which we obtained (Table 1). The hybrid protein synthesised by several of these Mal^R Lac$^+$ strains seems identical in size to the hybrid protein produced by the parental strain (Fig. 2). However, since these proteins for the most part are no longer membrane-associated, they are apparently subject to proteolytic degradation, most probably at their amino-terminal end, as indicated by the appearance of a second maltose-inducible band. This second band has an apparent molecular weight nearly identical to the monomer subunit of β-galactosidase (116,000). Such degradation has been observed with other hybrid proteins containing a β-galactosidase moiety[13,14].

In strain PB72-47, the amino-terminal extension provided by the MBP moiety of the hybrid protein presumably directs the hybrid protein into the cytoplasmic membrane. One possible explanation for the failure of these Mal^R strains to attempt to export the hybrid protein is that the protein produced by these strains has an altered amino-terminal signal sequence which the cell's export apparatus cannot recognise. If this is so, then the mutation responsible for the Mal^R phenotype must be genetically tightly linked to the hybrid gene. Since the *malE–lacZ* fusion is carried by a λp (plaque-forming) transducing phage, linkage information was obtained simply by isolating the λ phage from each Mal^R Lac$^+$ fusion strain and subsequently using it to lysogenise the *mal*$^+$ Δ*lac* strain MC4100. If the resultant lysogen is Mal^R Lac$^+$, the mutation must have been cotransduced with the hybrid gene. This proved to be so for all of a number of independently-isolated Mal^R Lac$^+$ strains.

Incorporation of signal sequence mutations into the *malE* gene

If the hybrid proteins synthesised by these Mal^R Lac$^+$ strains have an altered signal sequence, the mutations responsible must be located early in the *malE* portion of the hybrid gene. We determined the effect of these mutations on the localisation of

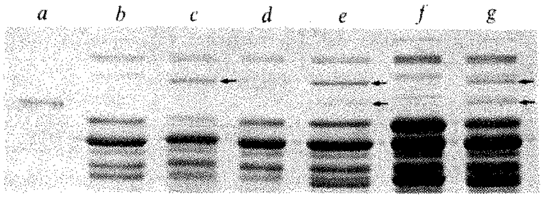

Fig. 2 SDS–polyacrylamide gel electrophoresis of whole cell extracts of *malE–lacZ* fusion strains. Whole cell extracts were prepared and electrophoresis was performed as described elsewhere[20]. Only the relevant upper one-third portion of the gel is shown. *A*, Purified *E. coli* β-galactosidase, 2.5 μg; *b*, strain PB72-47, uninduced; *c*, strain PB72-47, induced; *d*, strain PB72-47-R1, uninduced; *e*, strain PB72-47-R1, induced; *f*, strain PB72-47-R2, uninduced; *g*, strain PB72-47-R2, induced. The hybrid proteins are easily identified as maltose-inducible proteins of high molecular weight (arrows). In addition, Mal^R derivatives exhibit a second maltose-inducible band of molecular weight nearly identical to native *E. coli* β-galactosidase (arrows, see text).

the wild-type *malE* product, the MBP. As described in Fig. 3, these mutations could be recombined onto the wild-type *malE* gene. The resultant recombinants had a Mal$^-$ phenotype when scored on maltose tetrazolium agar, indicating that their ability to utilise maltose as a carbon source had been impaired. However, it was found that these strains would grow slowly on maltose minimal medium. Two of these strains (PB1101 and PB1102), derived from independently-isolated Mal^R Lac$^+$ fusion strains, were characterised further. The mutant alleles were designated *malE101* and *malE102*, respectively.

To confirm that the correct mutations had been incorporated into the *malE* gene by this construction, strains PB1101 and PB1102 were lysogenised by the *L*pp transducing phage carrying the original *malE-lacZ* fusion present in strain PB72-47. The lysogen obtained was maltose-sensitive, but Mal^R Lac$^+$ derivatives were obtained at a very high frequency, a result of the reciprocal recombination event described in Fig. 3. In a similar manner, it was found that the *malE101* and *malE102* mutations could be incorporated by recombination into the hybrid gene of the maltose-sensitive fusion strain PB62-37 (again, resulting in a Mal^R Lac$^+$ phenotype). Since only a small promotor-proximal portion of the *malE* gene is present in this fusion (Fig. 1), this indicates that the *malE101* and *malE102* mutations must, indeed, be located early in the *malE* gene. More precise mapping was complicated by the fact that strains PB1101 and PB1102 can still utilise maltose as a carbon source.

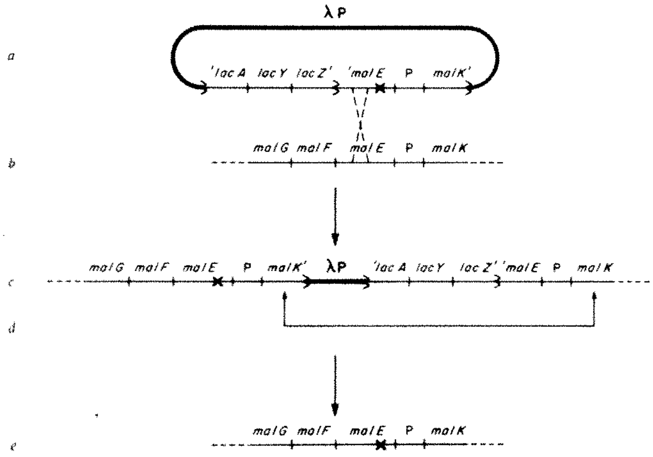

Fig. 3 Recombination of the *malE101* mutation onto a wild-type *malE* gene. *a*, the λp transducing phage that carries the *malE–lacZ* hybrid gene from strain PB72-47-R1. The mutation *malE101* is indicated by an ×. (*b*) A portion of the chromosome of the *mal*$^+$ strain MC4100 which includes a wild-type *malE* gene. The λp transducing phage is Δ*att* and strain MC4100 is Δ*lac*. Thus, lysogenisation can most efficiently be achieved by recombination between their homologous *mal* DNA regions. Integration of the phage DNA as drawn results in a lysogen (*c*) in which the *malE101* mutation has been crossed onto an intact *malE* gene. Curing of the phage DNA by the slightly different homologous crossover indicated by the arrows (*d*) leaves the *malE101* mutation behind in the chromosome (*e*), yielding strain PB1101. Strain PB1102 was constructed in an identical manner.

Identification of a mutant MBP precursor

As it appeared that there might be a defect in the export of the MBP in the mutant strains, cell extracts of strains PB1101 and PB1102 were examined for the form and location of the mutant proteins. Whole cell extracts were prepared from cultures that had been grown on glycerol (uninduced) or maltose (induced) and examined on SDS-polyacrylamide gels (Fig. 4). The maltose-inducible band corresponding to wild-type MBP is not present with either strain. However, a new maltose-inducible band is discerned which migrates with a molecular weight some two to three thousand larger than native MBP. This protein is very similar in size to that reported for the MBP precursor made *in vitro*[9].

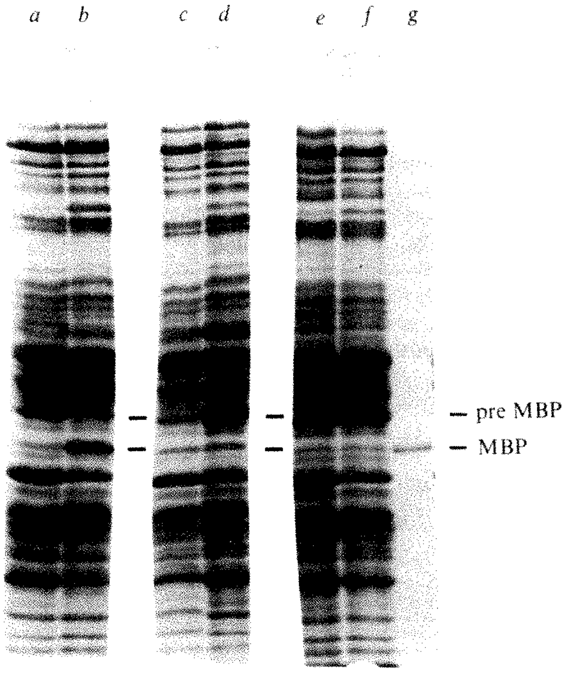

Fig. 4 SDS-polyacrylamide gel electrophoresis of whole cell extracts of *malE* mutant strains. Whole cell extracts were prepared and electrophoresis was performed as described elsewhere[20], except that the acrylamide concentration here is 10%. *a*, Strain MC4100, uninduced; *b*, strain MC4100, induced; *c*, strain PB1101, uninduced; *d*, strain PB1101, induced; *e*, strain PB1102, uninduced; *f*, strain PB1102, induced; *g*, purified *E. coli* native MBP, 2.0 μg. The position of native MBP in the *mal*$^+$ strain MC4100 and the position of the presumed MBP precursor (preMBP) in the two mutant strains are indicated. Everything shown in the figure is from the same slab gel.

The simplest explanation for these results is that strains PB1101 and PB1102 produce a MBP with an altered amino-terminal signal sequence. This sequence is not recognised by the cell's export apparatus and the protein accumulates in the cytoplasm in its larger (unprocessed) form. Different cell fractions of strains PB1101 and PB1102 were prepared and run on SDS gels, in order to determine the cellular location of this new maltose-inducible protein. A maltose-inducible protein which is larger than native MBP is observed in soluble extracts from both strains. This protein is somewhat smaller than the presumed precursor observed in whole cells and is believed to correspond to a breakdown product of the precursor. Only minute amounts of this protein are released by the cell by a cold osmotic shock procedure which is used to operationally define periplasmic proteins in Gram-negative bacteria[15]. Therefore, this protein must be primarily located in the cytoplasm.

In order to verify that the presumed precursors observed in the mutant strains are, indeed, related to the MBP, antiserum prepared against native *E. coli* MBP was used to immune precipitate the soluble extract from a maltose-grown culture of strain PB1101 labelled with ^{14}C-amino acids (Fig. 5). The new maltose-inducible protein observed by gel electrophoresis of the soluble extract of strain PB1101 was specifically precipitated by this antiserum. In addition, several minor proteins in the same molecular weight range were precipitated from the mutant extract. Since none of these proteins was precipitated when the antiserum was pre-incubated with purified, unlabelled MBP, it was concluded that all of the proteins precipitated were antigenically related to MBP. One of the minor proteins so precipitated ran on the gel with an apparent molecular weight identical to native MBP. This may represent a small amount of MBP that was exported to the periplasm in the mutant strain and correctly processed, allowing strain PB1101 to utilise maltose as a carbon source, albeit inefficiently. Additionally, a minor protein so precipitated from the mutant strain ran with the same apparent molecular weight as the presumed precursor observed in whole cells (see Fig. 4). We conclude that this protein is the MBP precursor, and that it is fairly stable in whole cells. However, when the cells are disrupted under non-denaturing conditions, this protein is subjected to some proteolytic degradation, and very little remains intact even though all manipulations are performed at 4°C. Presumably, the enzyme(s) responsible for this proteolytic degradation are located in the periplasm or outer membrane where they are not accessible to the mutant MBP precursor until the cells are broken. However, these do not necessarily have any relationship to the enzyme(s) responsible for processing normal exported proteins to their mature sizes.

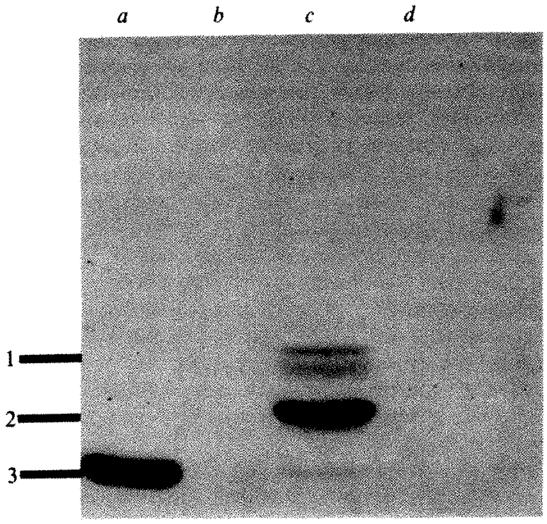

Fig. 5 Immune precipitation of MBP from soluble extracts of strains MC4100 and PB1101. 500 ml cultures were grown in maltose minimal medium to mid-log phase and labelled with ^{14}C-amino acids (50 μCi, NEN) in a 50 ml volume for the final 60 min of culture. Cells were washed twice and resuspended in 5 ml of buffer (10 mM Tris, *p*H 7.2). Cells were then disrupted in a French pressure cell and twice clarified by centrifugation at 100,000 *g* for 1 h. 0.2 ml of the soluble cell extract, 0.1 ml [3 M NaCl, 3% Triton X-100, 10 Mm Tris *p*H 7.2] and 3 μl of rabbit anti-MBP serum (provided by W. Boos) were combined and incubated on ice for 3 h. 30 μl of sheep anti-rabbit IgG (Miles) were added, and the entire mixture was incubated overnight at 4° C. The precipitate obtained was washed three times with 10 mM Tris, *p*H 8.0 (1st wash, 1% Triton X-100; 2nd wash, 0.1 M LiCl; 3rd wash, 0.1% SDS). The final pellet was resuspended in 0.1 ml gel sample buffer, heated at 90 °C for 2 min, and 50 μl were loaded per well for electrophoresis. Finally, the gel was stained with Coomassie blue, dried and autoradiographed. *a*, And *b*, strain MC4100; *c*, and *d*, strain PB1101; *b*, and *d*, anti-MBP serum was pre-incubated for 30 min on ice with 10 μg of unlabelled native *E. coli* MBP. The three lines along the left side of the gel indicate the corresponding positions where the following three proteins are observed to run: (1), The MBP precursor observed in whole cells of strains PB1101 and PB1102. (2), The maltose-inducible protein observed in soluble cell extracts of strains PB1101 and PB1102. And (3), purified native *E. coli* MBP.

Reversion analysis

For both strains PB1101 and PB1102, we obtained *mal*$^+$ revertants by growing these strains in maltose minimal liquid medium through many generations. Since *mal*$^+$ revertants had a considerable selective advantage in such conditions, with time they accumulated to form the majority class of the population. Several independently-isolated revertants from both strains were characterised. In all cases, these appeared to be 'true' revertants, in that the MBP synthesised by these strains is made in normal amounts and found in the periplasm in its native form. That strains PB1101 and PB1102 spontaneously revert to wild-type *mal*$^+$ indicates that the mutations *malE101* and *malE102* result in single amino acid substitutions in the MBP polypeptide.

Discussion

Complete or partial amino acid sequences for the amino-terminal extension of a number of exported proteins have been reported (summarised by Habener *et al.*[16]). Most of these are from eukaryotes. All these sequences contain a central region of some 10 to 12 non-polar and hydrophobic amino acid residues, although it is a different sequence in each case. There is no other feature common to these primary structures which readily identifies itself as being key to its recognition as a signal initiating protein export. We have now isolated *E. coli* strains which fail to secrete the MBP, most probably resulting from mutational alterations in the signal sequence region of this protein. We are now determining the precise nature of the alterations, in order to define that feature of the signal sequence which is essential for initiating export. Confirmation of the location of the mutations in the portion of the *malE* gene corresponding to the signal sequence would provide direct evidence for its role in the initial steps of protein secretion.

Fusion strains have also been used to isolate mutants defective in the localisation of the *lamB* gene product, the phage λ receptor[14]. These mutations most probably result in alterations in the signal sequence of this protein which is normally located in the outer membrane of *E. coli*.

The discrete source component of galactic γ rays

THE question of the relative contributions from discrete sources and continuum to the flux of cosmic γ rays is a continuing one, with published estimates varying from a 10% source contribution[1] to more than 40%[2] and even to a possible 100%[3]. Since these estimates have mainly been based on parts of the necessarily incomplete set of only 13 known γ-ray sources[4], it is not surprising that such a wide variety of conclusions is possible. The basic reason is the limited angular resolution of contemporary γ-ray detectors ($\simeq 1.5°$), and it is unlikely that great improvements will be made in the near future.

A knowledge of the individual sources of γ rays (and their summed intensity contribution) is relevant to energetic processes in discrete objects, but our own prime interest relates to the fact that useful conclusions about the origin of the particle component of cosmic radiation can be obtained by an analysis of the continuum.[5] The derivation of the magnitude of the continuum after both seen and unseen discrete source contributions have been subtracted off is, therefore, an important task.

Some general guidance might be expected from an analysis of related regions of the electromagnetic spectrum. In X rays, where detectors of high angular resolution are used, the continuum contribution appears to be very small (probably $\lesssim 5\%$); however, that the observed γ rays are not the high energy 'tails' of the X-ray sources is immediately clear from the general lack of correlation of specific γ-ray and X-ray sources.

A comparison with the radio region is probably more relevant. Potential candidates for producing the continuum γ rays are electrons of energy of the order of 1 GeV interacting with the interstellar medium by way of bremsstrahlung and protons of energy 1–10 GeV interacting with the same medium and producing π^0 mesons which in turn decay to γ rays. The relevance of the radio region is that it is generally accepted that the bulk of the radio flux (in the range 10–1,000 MHz) is produced as synchrotron radiation from electrons spiralling in the galactic magnetic field. One GeV electrons produce radiation with frequency 150 MHz and Brindle *et al.*[6] have presented evidence which shows that the continuum radiation provides at least 95% of the flux. Thus, such indirect evidence as there is suggests a predominance of the continuum contribution.

It is apparent from an examination of the longitude distribution of the total γ-ray flux that sources distributed in a similar fashion to main sequence stars are not responsible for much of the flux. The expected large peak towards the galactic centre is absent. Furthermore, the latitude distribution of γ rays is much sharper than that of starlight. Instead, it is likely that the sources have a similar spatial distribution to that of young objects (such as, HII regions), evolved objects (pulsars, supernova remnant) or X-ray sources (the fact that there is not a one-to-one correspondence with known X-ray sources does not preclude this).

We aim here to derive more reliable estimates of the discrete source contribution using both a simple geometrical model and properties of X-ray sources and pulsars as a guide. Since these different approaches lead to very similar results there is some justification for confidence in their validity.

We consider separately the contributions from two possible types of source population: (1) sources with high intrinsic luminosity and low space density (HP sources) and, (2) sources with low intrinsic luminosity and high space density (LP sources).

In the simplest version of the model the sources are distributed uniformly throughout a slab of half thickness z_0. The differential source count frequency from HP sources will then be $N(S) \propto S^{-2}$ for distances r much greater than z_0 and the sources will be closely confined to the galactic plane, while LP sources are numerous enough to give a large number nearer than $\simeq z_0$, these nearby sources being isotropically distributed on the sky. This differentiation of source populations shows very clearly the dependence of the derived limits on the space density of the sources. The use of this double δ-function luminosity function is adequate provided we restrict attention to low latitudes where geometry should influence $N(S)$ more than the luminosity function.

The sources observed by COS B are concentrated within a few degrees of the galactic plane and are therefore of the HP population. For such a population $S_N \propto 1/N$ on average, where S_N is the observed intensity of the N'th brightest source. Using the observed intensities of the N_{obs} brightest sources we can estimate the total intensity of the whole population as

$$J_{\text{T}} = \sum_1^{N_{\text{obs}}} S_{\text{N}} \cdot \sum_1^{N_{\text{max}}} \frac{1}{N} \bigg/ \sum_1^{N_{\text{obs}}} \frac{1}{N} \qquad (1)$$

where $N_{\text{max}} = (r_0/r_1)^2$ is the total number of sources within the distance to the boundary at $r = r_0$ and r_1 is the distance to the nearest source. Equation (1) is intended to minimise the statistical error on the estimate of J_{T} by making use of the summed flux from known sources explicitly. (As written it applies simply to a small range of longitudes over which r_0 can be regarded as constant.)

We apply this result to three COS B observation regions $l = 305°$–$335°$, $60°$–$90°$ and $110°$–$140°$ for which a systematic search for sources has been made[4] and $N_{\text{obs}} = 8$. The anticentre region has been excuded since two-dimensional geometry is probably inappropriate there. Equation (1) then becomes

$$J_{\text{T}} = \text{J}_8 \times 0.37(0.62 + 2\ln(r_0/r_1)) \qquad (2)$$

From ref. 4, $J_8 = 3.8 \times$ Crab flux $= 1.3\ 10^{-5}\ \text{cm}^{-2}\ \text{s}^{-1}$ (>100 MeV) (using the measured Crab flux of $3.5 \times 10^{-6}\ \text{cm}^{-2}\ \text{s}^{-1}$). The main uncertainty is the value of r_0/r_1, although this is not critical because of the logarithmic dependence in equation (2). Since the bright observed sources have latitudes $|b| \simeq 0$–$3°$, the magnitude of r is in the range 1–2 kpc if the thickness $2z_0$ of the galactic source layer is about 200 pc. (a value typical of young objects). The value of r_0 lies in the range 10–20 kpc for the regions considered, so that $J_{\text{T}} = (1.4$–$2.4)J_8 = (1.8$–$3.1)10^{-5}\ \text{cm}^{-2}\ \text{s}^{-1}$ and the average line flux is $(0.9$–$1.5)10^{-5}\ \text{cm}^{-2}\ \text{s}^{-1}\ \text{rad}^{-1}$ (>100 MeV). The average observed total line flux for these regions is $3.8 \times 10^{-5}\ \text{cm}^{-2}\ \text{s}^{-1}\ \text{rad}^{-1}$ (for $|b| < 6°$) so the analysis indicates that between 24% and 40% is from sources.

Source density gradients in the Galaxy may make the use of a uniform two-dimensional geometry inappropriate for the $l =$ 305–335° region because one is here looking in a direction not far from that of the galactic centre; however, for the regions $l = 60°$–$90°$ and $110°$–$140°$, where the gradient is probably small, the average line-flux is $2.8\ 10^{-5}\ \text{cm}^{-2}\ \text{s}^{-1}\ \text{rad}^{-1}$ ($|b| < 6°$)

0028-0836/79/0277—0542$01.00

Table 1 Alternative estimates of the fraction, f, of γ rays above 100 MeV from discrete sources

Model	Longitude intervals (γ-ray observations)	N	J_T/J_N	$j_S \times 10^5$ cm^{-2} s^{-1} rad^{-1} (>100 MeV)	f
Flat slab	1, 2, 4	8	1.4–2.4	0.9–1.5	0.24–0.40
	1, 2	8	1.4–1.9	0.9–1.2	0.32–0.42
X-ray sources	1, 2, 3, 4	12	1.1	0.9	0.19
Pulsars	1, 2, 3, 4	12	1.05	0.9	0.18

Longitude key: 1, 60°–90°; 2, 110°–140°; 3, 160°–210°; 4, 305°–335°.

and $r_1 \simeq 10$ kpc. Hence $J_T = (1.4–1.9)J_8$ and the discrete source fraction is 32–42%.

A second approach to the HP component follows ref. 3 in assuming that the form of the observed brightness distribution $N(S)$ for X rays is similar to that for γ rays. Since the known sources do not have a constant ratio of γ-ray to X-ray flux, as remarked earlier, we postulate that while γ-ray sources are different objects from X-ray sources, their spatial distribution, luminosity function and total number are approximately the same as for X-ray sources. Since both populations have their brightest sources confined to within a few degrees of the plane a similar spatial distribution at least seems probable. In applying this method we again confine attention to the COS-B observation regions which have been systematically searched for γ-ray sources (the anticentre region can now be included since no particular geometry is assumed). The 72 4U sources[7] in these four areas are found to have a value of J_T/J_N for X-rays which is smaller than for a simple slab model (a consequence of the flattening of the X-ray $N(>S)$ to $S^{-0.4}$ below 200 Uhuru counts). This method gives a slightly lower value for f than the slab model (Table 1). It is interesting to note that if the $N(>S)$ versus S distributions for X-ray and γ-ray sources are normalised at the S intensities for the Crab, then the value of f is virtually the same as found using the method described above.

Although the particular assumptions made in the $N(S)$ method are unlikely to be completely justified the comparison of this result with that from the slab model does indicate that the sensitivity of the estimates to the type of (HP) source population involved is small enough to make the exercise worthwhile.

Another useful deduction from the X-ray data can be made as follows. A prominent feature of the X-ray sources is that there is a much bigger intensity in the general direction of the Galactic Centre than elsewhere. Restricting attention to X rays (and γ rays) within a latitude range of $|b| < 10°$ the ratio of total X-ray intensity in the inner Galaxy to that in the outer is $I_X(270° < l < 90°)/I_X(270° > l > 90°) \simeq 9.4$. This ratio can be compared with that for γ rays above 100 MeV of 2.2. (If the contributions from the Crab (which dominates in the X-ray case) are taken out the ratio is as high as 34 for X rays and only 2.4 for γ rays.) An upper limit can be set as the fraction of the flux of γ rays in the outer direction coming from discrete sources by assuming that the whole of the flux from the inner direction is from such sources. Adopting a ratio of 9.4, which is itself a lower limit, we find $f \simeq 0.25$, that is, in the range $270° > l > 90°$ no more than 25% of the γ-ray intensity is produced by X-ray sources or sources distributed in the Galaxy in a similar fashion to X-ray sources.

For the third estimate of the HP contribution, we have taken the radio fluxes from the Arecibo deep pulsar survey[8], covering $|b| < 4°$, $43° < l < 58°$. This was chosen for its completeness to low radio fluxes, although the region covered is much more restricted than the COS-B observation areas. A similar result to that for X rays is obtained (Table 1). Comparison can be made with our earlier estimate[1] for pulsars ($f = 0.05–0.10$). The fact that the new value is a factor of 2 higher is not surprising since the new result refers to sources in general with an observed intensity distribution similar to that of pulsars whereas the earlier value related to pulsars alone (with a model in which the γ-ray luminosity was proportional to the radio luminosity).

Turning to the LP sources, we estimate the minimum density of such sources which would be required to produce a fraction f of the galactic plane emission without being visible as discrete sources above the current COS B threshold of $S_{\min} \simeq 0.2 \times$ Crab flux. A uniform slab model with thickness $2z_0$ and radial extent r_0 gives a minimum source density

$$\rho = \left\{\frac{1}{2z_0} \cdot f \cdot \frac{j_{\text{obs}}}{S_{\min}} \cdot \frac{1}{[1 + \ln (b_0 r_0/z_0)]}\right\}^3 \left(\frac{\Omega}{3}\right)^3 \tag{3}$$

where Ω is the solid angle of the area of sky considered and j_{obs} is the observed total line-flux. Using $z_0 = 0.1$ kpc, $b_0 = 10°$, $r_0 = 10$ kpc, $\Omega = 1$ sr for the COS B regions $l = 60°–90°$, $110°–140°$ and $305°–335°$ gives

$$\rho \simeq 10^5 f^3 \text{ kpc}^{-3}$$

or a total number of LP sources in the Galaxy of the order of $10^7 f^3$. For $f = 1$ this is about three orders of magnitude lower than that of main sequence stars, but two orders of magnitude higher than that of likely sources such as pulsars[9] and a possible population of weak X-ray sources[10] (up to 10^5 sources with X-ray luminosity 10^{32} erg s^{-1}). Alternatively, we can state that a maximum of about $100^{-1/3}$, that is, 20%, of the galactic emission could originate in sources of this latter density.

In conclusion, Table 1 shows that the most likely value of f is $\simeq 0.25$ although it could be as high as 0.4 (and not inconsistent with the estimate of Bignami *et al.*[2]). Such a value would not invalidate the interpretation of γ-ray data in terms of a gradient of cosmic rays in the Galaxy, at least in the outer Galaxy[5]. A final remark is that the so-called discrete sources of γ-rays will include complexes of molecular clouds which provide target nuclei for cosmic rays; a derivation of their contribution must await more comprehensive surveys of such cloud complexes.

Creation of magnetic monopoles in pulsars

THE symmetry of the free Maxwell equations under transformation of electric field into magnetic field led Dirac[1] to suggest the existence of magnetic monopoles. Many experimental searches for these particles have been made on different accelerators and using cosmic ray interactions; no magnetic monopoles having been detected, upper limits of the cross sections for the creation of monopoles have been obtained. The data of Ross *et al.*[2] are the best and can be fitted by:

$$\sigma_{\text{pn}} \leqslant 5 \times 10^{-44}\, m_g^3 \tag{1}$$

where σ_{pn} is the proton–nucleon cross-sections in cm^2, and m_g

0028–0836/79/0277—0543$01.00

the monopole mass in GeV c^{-2}. It is believed[3,4] that very energetic particles are created in pulsars. These particles can interact between themselves and/or be smashed onto the neutron star surface to produce pairs of magnetic monopoles and antimonopoles. These monopoles (if they exist or are effectively produced) would be accelerated in the pulsar magnetic field, one species towards the interstellar medium, the other towards the neutron star, producing a decrease in the magnetic field. Such a phenomenon can be related to observations, particularly to the discrepancy between the characteristic and the kinematical ages. We show here that these observations can be explained by a production of magnetic monopoles, inherent to the pulsars, with a cross-section lower than equation (1), (that is, without contraction with the negative results of the terrestrial searches). More specifically, we will consider the magnetic monopoles production on the neutron star surface, in the Ruderman and Sutherland model[4]. Other models (with and without gaps) will be considered elsewhere.

Ruderman and Sutherland[4] argue that the creation of polar gaps should take place in pulsars. These polar gaps would be broken by electron pair creation and the subsequent avalanche development, with the potential across the gap

$$V = 1.6\times10^{12}B_{12}^{-1/7}T^{-1/7}\rho_6^{4/7} \tag{2}$$

where $\rho = 10^6\rho_6$ is the curvature of the magnetic field lines at the neutron star surface in cm. The creation of magnetic monopoles is then possible due to the electrons accelerated by the potential of equation (2) across the gap and which crash on the neutron star crust.

The energy threshold E_{eth} for creation of monopoles with the mass m_g on the crust nucleons of mass m_n is

$$E_{\mathrm{eth}} \approx 2m_g^2 m_n^{-1} \tag{3}$$

With the energy eV given by equation (2), the electrons have enough energy to create monopoles with $m_g \leqslant 30$ GeV c^{-2}. Inside the neutron star crust, the electrons lose their energy due to bremsstrahlung and the number of nucleons seen by the electrons before they are slowed down below the threshold energy for monopole creation is

$$\kappa_e \approx \beta X_0 \approx 8.4\times10^{24}\,\beta \quad \text{nucleons cm}^{-2} \tag{4}$$

where X_0 is the radiation length and $\beta = \log(\mathrm{eV}/E_{\mathrm{eth}}) \approx 1$ practically independent upon the pulsar properties. The flux of the magnetic monopoles pairs produced in one polar gap is

$$j_g = \kappa_e \pi r_p^2 nc\sigma_{\mathrm{en}} \approx 6.3\times10^{54}\, B_{12}R_6^3T^{-2}\sigma_{\mathrm{en}} \text{ monopoles s}^{-1} \tag{5}$$

where σ_{en} is the cross-section for the monopole creation in the electron–nucleon interactions. The radius of polar gap r_p and the density of created e^+e^- pairs, n, are given in ref. 4.

Kalman and Ter Haar[5] pointed out that the magnetic monopoles are accelerated by the pulsar magnetic field up to 10^{18} eV and interacting with neutron star crust should produce a cascade of 'secondary' monopoles. They estimate the number of secondary monopoles produced by a primary monopole to be

$$N^* = 6\times10^7\, B_{12}^{1/4}\rho_6^{1/2}n_g^{-1/4}m_g^{-1} \tag{6}$$

where n_g is the magnetic monopole charge in units of 137 e. Half of the monopoles which could be produced in this model are accelerated towards the neutron star surface and with the multiplicity this gives a decrease in the pulsar magnetic field at a rate

$$\frac{\mathrm{d}B}{\mathrm{d}t} = -\frac{j_g N^*}{4}\frac{137\, n_g e}{R^2} \tag{7}$$

It is commonly assumed that the slowing down of the pulsar results from the loss of rotational energy by magnetic dipole radiation. This allows us to estimate the neutron star magnetic field as a function of the period T and of its derivative $\dot{T}$

$$B \approx 8.3\times10^{18} I_{44}^{1/2}R_6^{-3}(T\dot{T})^{1/2} \quad \text{G} \tag{8}$$

where $I = 10^{44}\, I_{44}$ is the moment of inertia of the neutron star in g cm^2 and $R = 10^6R_6$ is its radius in cm. Equation (7) can then be integrated and the magnetic field expressed as a function of the period T:

$$B(T) = B_i\left\{1 - \frac{\sigma_{\mathrm{en}}}{\sigma_{\mathrm{crit}}}\log\left(\frac{T}{T_i}\right)\right\}^{4/7} \tag{9}$$

with

$$\sigma_{\mathrm{crit}} = 6\times10^{-46}\frac{R_6^5B_{i12}^{7/4}}{I_{44}\rho_6^{1/2}}\frac{m_g}{n_g^{3/4}} \quad \text{cm}^2$$

where T_i and B_i are the period and the magnetic field at the creation of the gap ($\approx$ the creation of the pulsar).

There are observations to test this decrease in the magnetic field. First, it implies that the characteristic ages $\tau = T/2\dot{T}$ are not true indicators of the real ages but must be greater. Actually there is a discrepancy between the kinematical ages τ_k (obtained from the direct measurements of the proper motion and the distance from the galactic plane of the pulsars) and the characteristic ages, which seem greater[7]. For those pulsars whose proper motion was measured, the mean kinematical age is $\langle\tau_k\rangle = 1.3\times10^6$ yr while the mean characteristic age is $\langle\tau\rangle = 5\times10^6$ yr, and if the same mean velocity is used for all the pulsars a much larger discrepancy is found. Furthermore, some pulsars are remarkable because of their extraordinarily great characteristic ages—up to 10^9 yr—a fact which could very well be explained by a decrease in the magnetic field, too. Considering equation (9), it can be seen that the creation of magnetic monopoles in pulsars may explain these observations if $\sigma_{\mathrm{en}} \leqslant \sigma_{\mathrm{crit}}$. When this cross-section is compared with the upper limit of equation (1) from the monopole searches using cosmic rays, it can be seen that there is no contradiction with this explanation and the fact that monopoles are not observed directly: expecting that the alpha-numeric coefficient $R_6^5B_{i12}^{7/4}/I_{44}\rho_6^{1/2}$ to be of the order of unity, we have for the monopole production cross-section in pulsars:

$$\sigma_{\mathrm{en}} \leqslant 6\times10^{-46}\frac{m_g}{n_g^{3/4}} = 3\times10^{-44}\ \text{cm}^2$$

$$\text{for } m_g = 30 \text{ GeV } c^{-2} \text{ and } n_g = 0.5 \tag{10}$$

which is considerably smaller than the terrestrial upper limit of equation (1):

$$\sigma_{\mathrm{pn}} \leqslant 10^{-39}\ \text{cm}^2 \quad \text{for} \quad m_g = 30 \text{ GeV } c^{-2} \tag{11}$$

(Besides, the interactions for the production of monopoles in pulsars involve high energy electrons, while the upper limits published so far concern nucleons.) Therefore, as an explanation of the discrepancy between τ and τ_k and of the very great characteristic ages, we suggest that this comes from a decrease in magnetic field due to monopole creation in pulsars with the cross-section of equation (10). This provides an indication of the existence of the magnetic monopoles and of their creation in pulsars or at least (if another explanation for the observations is preferred) a new upper limit on the monopole production cross-section, far more stringent than the terrestrial ones.

Possible nuclear origin of Ap and Am stars

MANY possible mechanisms have been proposed to explain the abundance anomaly of heavy elements on Ap and Am stars. Van den Heuvel[1] suggested that these stars had been secondaries of binary systems, whose primaries exploded as supernovae and caused the accretion of heavy elements on the secondaries. The abundance distribution of elements with $Z \geqslant 40$ in those stars is generally similar to that of r nuclei in the Solar System, although the overabundance factor for each element relative to Solar System r abundance is not constant, being exceptionally high in some limited regions such as the region around Te, the rare earth region around Nd and Sm, and around Pt and Hg. These observational trends suggest that the abundance pattern in those stars may be a superposition of some specific elements with anomalously high abundance on a background proportional to the Solar System r abundance. Here I suggest an alternative possibility for the nuclear origin of anomalous abundance in Ap and Am stars.

In the early expanding period of supernova shells, the Rayleigh–Taylor instability[2], plasma instabilities or, at a later period, some instability accompanying dust formation[3] would occur. These instabilities might cause more or less pronounced density and composition inhomogeneities and chemically inhomogeneous clumps or knots of clouds might appear in the expanding shells. The clumps would have envelopes surrounding them[2], so that the movement of these clumps would generate turbulence in the expanding shells and tend to chemically homogenise the supernova shells. We can therefore imagine that in the expanding supernova shells there are chemically inhomogeneous clumps embedded in and co-expanding with the chemically homogeneous background gas. These clumps would appear $\leqslant 4 \times 10^{14}$ cm from the supernova[2]. Taking the distance between the components of a typical binary system to be $\sim 10^2$ AU, the instabilities in the shells would occur during the transfer towards the secondary, and the accreting matter on the secondary would probably be composed of some clumps and the background gas, now partially chemically homogenised.

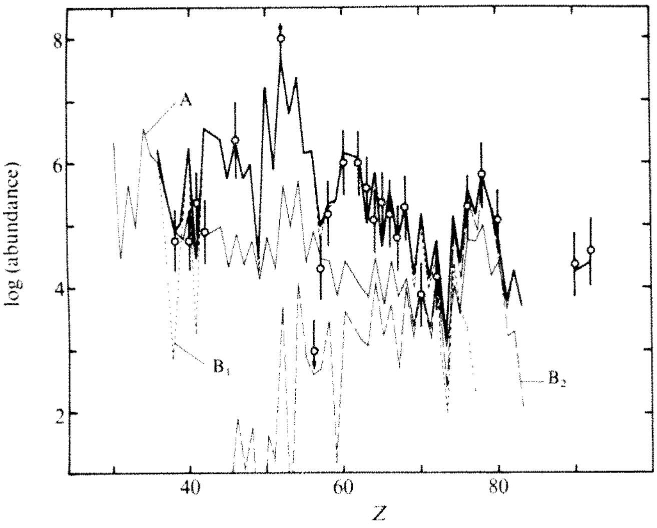

Fig. 1 Abundances of heavy elements on HR465 in the scale $H = 10^{12}$. Open circles with error bars show observations, whereas the heavy solid lines denote the calculated abundances. Arrows indicate the data with only upper or lower limits. Observational uncertainties are unclear but are assumed here arbitrarily to be ±dxp(0.5), although they could be higher. The calculated abundances are composed of the background (A) and two components B_1 and B_2 intrinsic for HR465. They are shown by light solid, short dashed and long dashed lines, respectively. Abundance patterns for the component A in the region of $Z \geqslant 90$, B_1 in $42 \leqslant Z \leqslant 68$ and B_2 in $74 \leqslant Z \leqslant 80$ are substantially the same as those given by the heavy solid lines.

If we restrict the discussion to the region $Z \geqslant 40$, the nuclei formed in the supernova shells are only r and p nuclei. Using Arnett's model[4] of the presupernova with $M_\alpha = 8M_\odot$, I have investigated the nuclear synthesis occurring in the innermost shell of exploding supernovae[5]. The r process is found to take place when the star is within the lagrangian mass range $M_r = 1.34\text{–}1.69 \times 10^{33}$ g. The number of free neutrons per seed nucleus gradually increases with the decrease of M_r in that lagrangian mass range, and therefore the appearance of the abundance curve of produced r nuclei varies with position in the r shell. The shell-intergrated abundance over the r shell, however, can well reproduce the relative abundances of r nuclides in the Solar System. If the r nuclei are produced in the above lagrangian mass range, they become overabundant in the supernova shells as a whole by a factor of $\sim 3 \times 10^4$ as compared to the Solar System r abundance, whereas the overproduction factor for the p nuclei is 10^{0-3} only in the p nuclei-producing region[6]. Hence in the region $Z \geqslant 40$ the abundance distribution in the background gas which accretes on the secondary star would be substantially that of the r process. However, some accreting clumps with a high abundance of r elements might be produced at some position in the r shell. Where these clumps accrete, chemically inhomogeneous spots with intrinsic distribution of r elements would form. It would therefore be possible to observe the abundance distribution due to these spots, being superimposed on the background distribution. The extent of the strong overabundance in some specific elemental regions depends on the mass of accreting clumps relative to the mass of accreting homogeneous gas.

Cowley[7] points out that in the rare earth region the abundance of individual elements in Ap and Am stars can be expressed as two components—the ordinary abundance pattern with a normal odd-even effect (component A), and an abundance distribution with a maximum centred around intermediate rare earths (component B). According to my proposed model, these components A and B correspond, respectively, to the background with the r abundance appearance and to the intrinsic component originating from a chemically inhomogeneous spot.

As an example, consider HR465 observed in 1960 at its rare earth maximum. Figure 1 shows the observations[8–10] in the region of $Z \geqslant 40$ together with the theoretical abundances which consist of the 'background' (this is proportional to the r abundance observed in the Solar System[5,11]: component A) and two components B_1 and B_2 intrinsic for HR465. The components $B_{1,2}$ have the r abundances produced in the regions around $M_r = 1.48$ and 1.37×10^{33} g, respectively. The calculated abundances have been obtained by the superposition of three components so as to minimise the deviation from observations. The relative numbers of nuclei with $Z \geqslant 36$ are

$$A : B_1 : B_2 = 1.0 : 35.5 : 0.45$$

The calculation can well explain the observed data within the observational uncertainties. The component B_1 makes the regions around $Z = 42$, 52 and 60 overabundant, while component B_2 has a maximum centred around Pt. The abundances observed in the other Ap and Am stars are also explained by superimposing some intrinsic abundance patterns on the 'background'. We also expect to observe stars which do not require an additional intrinsic component, and which are explained by the 'background' component. Stars such as 32 Aqr, 63 Tau and γ Equ = HD201601 might be of this type.

Figure 2 shows the mass fraction of the region where a given element is produced in excess to the total mass of the r shell. A given element is said to be in excess at some position i in the r shell when the quantity $N(Z)_i - \langle N(Z) \rangle$ becomes positive, where $N(Z)_i$ is the number of nuclei with Z per unit mass produced at i and $\langle N(Z) \rangle$ is the average value over the entire r shell. Figure 2 implies that, if the sites for Rayleigh–Taylor

0028–0836/79/0277—0545$01.00

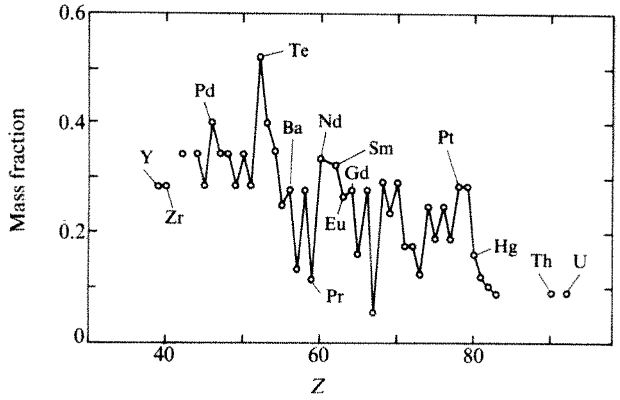

Fig. 2 Fraction of the mass of the region where a given element is produced in excess relative to the total mass of the r shell. Atomic symbols are given for representative elements frequently observed in Ap and Am stars.

instability or plasma instability are randomly distributed in the r shell, the probability that elements near $Z = 52$ will appear in Ap and Am stars with exceptionally high overabundance factors compared to the other elements is by about twofold higher than the probabilities for the other elements. Furthermore, in the light rare earth region the probability is slightly higher than that for heavy rare earths. The occurrence of Ap and Am stars with a high overabundance factor for a given element would show a pattern similar to that in Fig. 2 provided my hypothesis is the only mechanism operative.

Although the hypothesis well accounts for the gross feature of abundance curves on the Ap and Am stars, it cannot always explain the details of the curves; for example, it fails to explain the low abundances of Ba, La and Yb in HR465. For a complete and detailed explanation, secondary processes such as the magnetic accretion or the diffusion process would have to be introduced.

Consequences of the day-to-night variation of the exospheric temperature of Venus

DURING the exploration of the planet Venus by the Soviet space probe Venera 9, we measured the quantity of hydrogen in the upper atmosphere and its temperature through the optical observation of far UV atmospheric emission. The temperature at the altitude of 250 km (the upper boundary of the atmosphere) was found to vary from 500 K on the dayside to 200 K on the nightside. This variation is compatible with our current knowledge of the heating of upper atmosphere by the solar radiation. It is shown here that this variation, which is larger than on Earth, induces an exospheric transport (out of the atmosphere) of hydrogen from the dayside to the nightside. As an indirect consequence, this transport allows the existence of a large quantity of atomic oxygen in the upper atmosphere, a feature which was still controversial.

Atomic hydrogen in the upper atmospheres of planets is a good tracer of the exospheric temperature[1]. As it is produced through photochemistry of hydrogen compounds in the chemosphere, its distribution and total quantity are connected mainly to the mixing ratio of hydrogen compounds and to the efficiency of vertical transport[2,3]. As hydrogen atoms are scattering Lyα solar photons, they can be easily observed optically, from outside the atmosphere of the planet, through their Lyα emission at 1,215.6 Å.

The Lyα photometer which was flown in October 1975 in the orbiter part of Venera-9 around Venus, allowed intensity and line shape measurements to be made, which have been described previously[4]. The detector was a NO counter used in a photon counting mode, measuring the Lyα emission I_0 through a hydrogen absorption cell in a field of view of 20′. When the cell is activated at an optical thickness $\tau = 10 \pm 1$ (with the help of a tungsten filament which dissociates H_2 molecules into atoms), a part of the Lyα emission line is absorbed in the cell, and the intensity measured by the NO counter drops to $I_\tau = RI_0$. The reduction factor R is a function of the emission line profile and of the Doppler shift of the spacecraft along the line of sight[5].

Our previous report[4] was devoted to the analysis of the data obtained on the sunlit part of the atmosphere above the planetary disk. A hot component was found to be present about 3,000 km of altitude, and associated with the possible effect of the solar wind on the hydrogen exosphere, when it becomes turbulent after bow shock crossing. Below 3,000 km of altitude, the exospheric temperature T_c was found to vary on the dayside from one day to the other between 400 and 600 K, with a mean value of 500 K, associated with a density of 1.5×10^4 atom cm^{-3} at 250 km, the exobase level.

This report analyses the measurements of intensity and reduction factor obtained for lines of sight intersecting the planetary disk, both in the dark and bright parts. These measurements are compared with model predictions of intensity and linewidth, built from a vertical distribution of hydrogen and

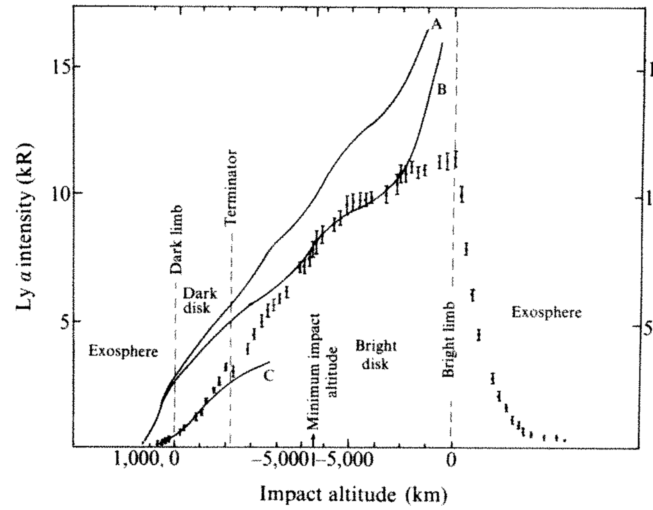

Fig. 1 The reduction factor (which measures the effect of the absorption cell on the Lyα signal when it is activated) is plotted as a function of impact altitude of the line of sight, counted negatively when the line of sight intersects the planetary disk. Theoretical curves are shown for various exospheric temperatures for comparison. The general decrease from left to right (increase of cell absorption) is due to decreasing Doppler shift. On the bright disk, the difference between measured and computed is attributed to contamination by O(I) 1,304 Å line. The observed temperature increase in the exosphere is attributed to bow shock interaction of decelerated solar wind protons with the hydrogen corona[4].

the solution of the radiative transfer equation in the approximation of a spherically symmetric exosphere[6]. The line profile is a by-product of the radiative transfer solution[7]; a theoretical value of the reduction factor R can then be computed, as the Doppler shift is known.

There is some contribution of the large emission of O(I) at 1,304 Å to our measured intensity signal over the bright disk data, as in the case of the Earth, even if our NO counter is less sensitive by a factor of $\simeq 3$ at 1,304 Å than at Lyα. We have used the hydrogen cell measurements for estimating the stray contribution of O(I) as follows.

The values of R measured over the disk are compared to the theoretical values computed for three hydrogen vertical distribution: same vertical distribution below 250 km with density at 250 km $n_c = 1.5 \times 10^4$ atom cm^{-3}, but three different exospheric temperature $T_c = 400$, 600, 800 K (Fig. 1). All curves, experimental and theoretical, decrease from left to right when the line of sight of the instrument scans the planet because during the same time, the Doppler shift due to the orbital motion decreases from -7.7 to -2.6 km s^{-1} and therefore the absorption peak in the cell moves towards the centre of the Venus emission line. When the Doppler shift is equal to the half-width of the absorption profile, one half of the emission line is absorbed and the other is not, whatever the line profile (within limits relevant to the present discussion), and therefore at that point all theoretical curves intersect at a value of $R = 0.5$ (ref. 8). The fact that, for this particular value, the measured R is >0.5 indicates the presence of a non absorbed signal which can be identified with the O(I) contribution to our signal and provides an estimate of its value. On all six orbits analysed, a subtraction of 23% of the bright disk intensities does bring back the measured values of R among the theoretical curves; this corresponds to a 0.8 ratio of the intensities $I(\mathrm{O(I)})/I(\mathrm{H})$, in fair agreement with previous measurements[9].

After subtraction of O(I) contamination (on the bright disk only), the intensity measurements were compared to theoretical intensities (Fig. 2) corresponding to two distributions of hydrogen. Both have the same exospheric distribution determined by $n_c = 1.5 \times 10^4$ at cm^{-3} at 250 km and $T_c = 500$ K (parameter deduced for the daylight exosphere from our previous analysis[4]). Below 250 km, the density follows the Liu and Donahue[10] model distribution with the following cloud top volume mixing ratios: $f_{\mathrm{HCl}} = 6 \times 10^{-7}$, $f_{\mathrm{H_2}} = 7 \times 10^{-8}$, $f_{\mathrm{H_2O}} = 3 \times 10^{-6}$ for model B and $f_{\mathrm{H_2O}} = 2.5 \times 10^{-6}$ for model A. Both models have the eddy coefficient K taken at 10^8 cm^2 s^{-1} and the limit of complete absorption of Lyα by CO_2 is set at 110 km. Differences between numerical values used by Liu and Donahue and us are of minor importance: we took, as our measurements indicated we should, $T_c = 500$ K instead of 350 K, and $n_c = 1.5 \times 10^4$ cm^{-3} at 250 km instead of $n_c = 10^5$ at 210 km. This last point corresponds to scaling down the Liu and Donahue density distribution by a factor of 5. According to the analysis of Sze and McElroy[11], this should imply approximately a decrease of hydrogen compounds at the cloud top level by the same factor of 5.

The results of the comparison are: (1) On the dark side, the theoretical intensities are nearly insensitive to hydrogen content below 250 km, region not illuminated: the main contribution comes from the part of the line of sight directly illuminated. Owing to the orbital configuration, this region of emission covers the twilight region behind the terminator, from 90° to roughly 120° of solar zenith angle. The measured intensities are much smaller than on either model, indicating that on the nightside of Venus the exosphere contains much less hydrogen than on the dayside. As shown on Fig. 2, a good fit is obtained with model C, identical to B below 250 km but with a lower temperature $T = 200$ K. Even lower temperatures would be required, if a density at exobase level was taken larger on the nightside than on the dayside, by analogy with the case of the Earth where the night-to-day ratio of hydrogen densities at the exobase level is of the order of 2, with a day-to-night temperature ratio of 1.3. We conclude that a large difference of exosphere temperature between day and night is demonstrated on Venus. A similar conclusion was reached from Mariner 5 results[12], but with a more complicated analysis restricted to limb measurements. Such a large day-to-night temperature ratio is indeed predicted from an elaborate theoretical model[13] of the upper atmosphere of Venus, which includes as a parameter the degree of efficiency of solar heating. Our dayside temperature of 500 K would correspond in this model to a medium efficiency solar heating.

(2) On the bright disk, the intensity is very sensitive to the hydrogen content below 250 km. A good fit is obtained with model B except near the bright limb, where field of view effects may smooth out the large theoretical increase. A Liu and Donahue model scaled down to our values gives a satisfactory description of the situation. We therefore have to discuss their conclusions. With their mixing ratio of hydrogenous compounds at cloud top (total hydrogen mixing ratio at least 10^{-6}) the production of hydrogen is large and because there are only three sinks (Jeans escape, non thermal escape, downward transport and recombination described by the eddy coefficient K) and as the Jeans escape is small, either the non thermal escape flux ϕ_{nt} or the eddy coefficient K must be very large. This places constraints over oxygen. If K is large, oxygen atoms are removed by transport and the dayglow at 1,304 Å is not due to optical resonance but to electron excitation. If K is small, oxygen atoms exist in large quantities and the dayglow is due to optical resonance, but in this case a very large non thermal escape flux is needed. The modifications our data force on the Liu and Donahue analysis ($T_c = 500$ K instead of 350 K, n_{250} scaled down by a factor of 5 which implies a value of $f_{\mathrm{H_2O}}$ around 0.5×10^{-6} at cloud top) do not change their conclusion. But what may change the discussion is the large asymmetry between day and night that we have demonstrated. On Earth, the density ratio adjusts itself to the temperature ratio in such a way that, at each point of the exobase, the upward flux of ballistic hydrogen atoms (a function of local conditions) is approximately equal to the downward flux of ballistic hydrogen atoms which comes from everywhere on the exobase. This seems not to be the case on Venus: the large difference in temperature between day and night, which results probably from the slow rotation of the planet, implies a large transport of hydrogen from the dayside to the nightside (or lateral flow) and the net upward ballistic flux

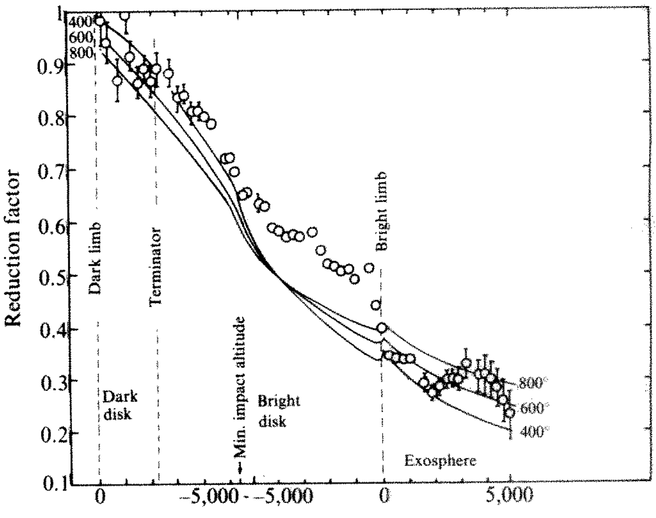

Fig. 2 The measured Lyα intensity (after subtraction of 1,304 Å contribution on the bright disk) is compared with computed intensities, for three different models A, B, C of hydrogen vertical distribution. A and B are different only below the exobase ($T_c = 500$ K) which shows that bright disk intensity is sensitive to hydrogen below the exobase. B and C are different only above the exobase, where model C is at $T_c = 200$ K. Dark disk intensity is sensitive to the hydrogen above the exosphere, directly illuminated by the Sun. $n_c = 1.5 \times 10^4$ atom cm^{-3}.

can become positive. For a sinusoidal variation of the temperature between $T_{\max} = 500$ K at the subsolar point and $T_{\min} = 200$ K at the opposite point, and a uniform density distribution $n_c = 1.5 \times 10^4$, we computed this net upward ballistic flux to be 5×10^7 atom cm^{-2} s^{-1} for the subsolar point. This upwards flux could very well play the role of the nonthermal escape flux ϕ_{nt} introduced by Liu and Donahue[10] and Sze and McElroy[11]. When reported on their Figs 2, 3, 4, $\phi_{nt} = 5 \times 10^7$ cm^{-2} s^{-1} implies low values of K of the order of 10^6 cm^2 s^{-1}. This value could, therefore, allow the atomic oxygen to build up and the 1,304 Å emission would be explained by resonance scattering.

Direct experimental verification of the Kelvin equation for capillary condensation

THE thermodynamic properties of liquids trapped in microscopic pores or existing as very small, highly curved droplets are described by the Kelvin equation[1]. This equation forms the basis of critical nucleation theory[2] and has been used in interpreting such diverse phenomena as adhesion[3], the enhanced solubility of small particles[2] and the retention and flow of liquids in porous materials[4–6]. The validity of the application of the Kelvin equation to such highly curved interfaces (where the mean radius of curvature can be in the range 1–100 nm) has been questioned[1,4], but has never been tested by direct experiment. We have used multiple beam interferometry to observe the formation of capillary condensed liquid between crossed cylinders of molecularly smooth mica. We report here that the Kelvin equation is obeyed by cyclohexane menisci with mean radius of curvature as low as 4 nm. We further conclude that the application of the laws of thermodynamics, and the concept of a bulk surface tension, are valid in principle for such highly curved interfaces.

The Kelvin equation[1] (equation (1)) gives the equilibrium mean radius of curvature r_m of a liquid–vapour interface in terms of the actual vapour pressure p and the saturated vapour pressure p_s. The equation can be applied to both liquid drops (r_m positive) and to bubbles and capillary-held wetting liquids (r_m negative)[2]. We have measured the mean radius of curvature of cyclohexane menisci at the periphery of liquid bridges trapped between two crossed cylindrical mica surfaces (Fig. 1) at equilibrium with relative vapour pressures in the range $0.71 < (p/p_s) < 0.94$, giving mean radii of curvature in the range $4\ \text{nm} < -r_m < 19$ nm. The experiments were carried out using an apparatus[7] in which the distance D between the molecularly smooth surfaces of a pair of rigidly mounted crossed cylindrical mica sheets was controlled and measured to ±0.1 nm. Distances were measured by multiple beam interferometry, which also

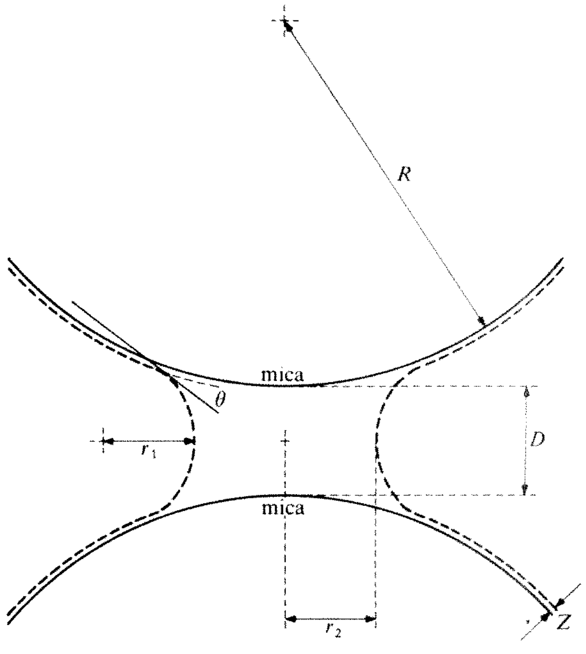

Fig. 1 Space between crossed mica cylinders with bridging meniscus (section through 45° plane of symmetry). Not drawn to scale: $R \approx 10^7$ nm, $r_2 \approx 10^4$ nm, $r_1 \approx -10$ nm. The mean radius of curvature r_m is defined as $1/r_m = 1/r_1 + 1/r_2$. By convention, r_1 is negative and r_2 positive in the configuration shown here. The equation used to calculate values of r_m from experimental values of the critical distance $D = D_c$ (see text) was $r_m \approx r_1 = -(D_c - 2Z)/2 \cos\theta$. This equation is accurate to within 0.5% for the range of values of r_m examined. The measured value of the contact angle θ was $\theta = (6 \pm 1)°$ (L.R. F., to be published).

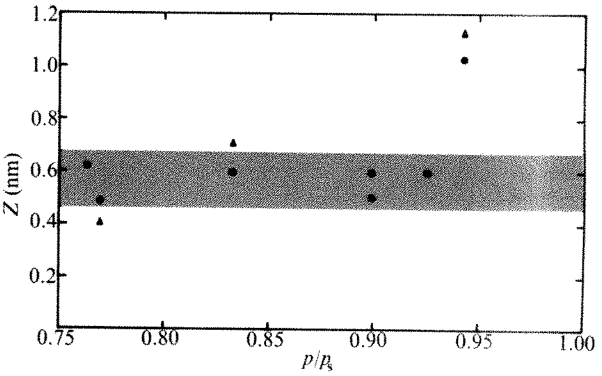

Fig. 2 Adsorption isotherm of cyclohexane on cleaved mica. Values of the adsorbed film thickness Z were determined (1) by measuring the distance (D_{contact}) between the mica surfaces at the moment of first contact, and assuming that $Z = D_{\text{contact}}/2$; or (2) by calculation from the measured root mean square refractive index (μ_{rms}) of the medium between the surfaces when the surfaces were held at a constant small distance (D) apart[8]. △, Points calculated from spacing at contact; ○, points calculated from r.m.s. refractive index. Shaded band: range of possible values of the thickness of a cyclohexane monolayer, calculated from measurements on a Courtauld spacefilling molecular model. We have taken $Z = (0.6 \pm 0.1)$nm for relative pressures below 0.93 and $Z = (1.05 \pm 0.1)$nm for $p/p_s = 0.943$.

0028–0836/79/0277—0548$01.00

permitted observation of the presence of a bridging meniscus and measurement of the refractive index of the material between the surfaces[8]. For distances D greater than a critical distance D_c, the liquid bridge evaporated irreversibly. Values of r_m were calculated from the experimental values of D_c, with allowance by simple subtraction for the thickness Z of the adsorbed film. Values of Z were determined from the adsorption isotherm at 293 K (Fig. 2).

The Kelvin relation between r_m and (p/p_s) is[9]:

$$\ln (p/p_s) = \{M/\rho_l RT\}\{(\gamma/r_m) - (p - p_s)\} \qquad (1)$$

where M is the molecular weight, ρ_l is the liquid density, p/p_s is the relative vapour pressure, γ is the liquid–vapour interfacial tension at the absolute temperature T, and R is the gas constant. As $|\gamma/r_m| \gg |(p - p_s)|$ for the range of values of r_m measured, this equation gives an almost linear plot of $\ln (p/p_s)$ versus $1/r_m$, with a slope of $[\gamma M/\rho_l RT]$. Two theoretical plots of $\ln (p/p_s)$ versus $1/r_m$ are shown in Fig. 3, together with the values of $1/r_m$ calculated from the experimental values of Z, D_c and θ at various experimental values of $\ln (p/p_s)$. The experimental points agree closely with those predicted by the Kelvin equation, assuming γ = constant, down to the smallest mean radius of curvature examined ($r_m = -4.2$ nm). If allowance is made for the effect of curvature on surface tension[10], a theoretical line is obtained with a slightly better fit to the experimental points. The assumption that an equilibrium adsorbed monolayer affects only the geometry of the system and not the meniscus curvature seems to be justified, although this assumption may need modification for thicker adsorbed layers[11].

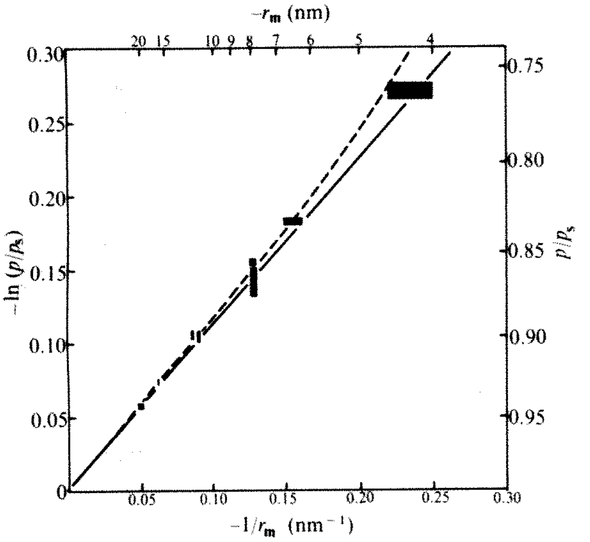

Fig. 3 Comparison of theoretical (Kelvin equation) plot of $-\ln (p/p_s)$ versus $-1/r_m$ with experimental results. The solid line corresponds to the assumption that γ ($= 25.5$ mN m^{-1}) is independent of r_m. The dashed line is calculated assuming the approximate relation[10] $\gamma = \gamma_\infty(1 + \Delta\lambda/r_m)$, where γ_∞ is the surface tension of a planar cyclohexane liquid–vapour interface and $\Delta\lambda$ is the 'thickness' of the interfacial region. We have taken $\Delta\lambda = 0.49$ nm (ref. 12). The relative pressure p/p_s was controlled by maintaining a constant temperature difference between the mica surfaces and a pool of liquid cyclohexane in the chamber of the apparatus. Errors in (p/p_s) are due to temperature drifts during an experiment. The principal errors in r_m arise from uncertainty in the thickness of the adsorbed film (about ±0.1 nm) and from errors in establishing the limits at which menisci were clearly observed to evaporate irreversibly (upper limit for D_c) or to grow (lower limit for D_c).

In conclusion, we have verified that the Kelvin equation for cyclohexane condensed on to mica surfaces is satisfied to within ±6% of r_m down to meniscus radii of 4 nm. A more detailed account of this work will be published elsewhere.

Measurement of carbon tetrafluoride in the atmosphere

ATMOSPHERIC trace concentrations of carbon tetrafluoride (CF_4) in a variety of ambient air samples have been measured. The air samples were concentrated by a cryogenic trapping technique and the CF_4 species identified by combined gas chromatography–mass spectrometry (GC–MS) with single ion monitoring. The contribution of natural and/or anthropogenic sources to the global burden of CF_4 is unknown. CF_4 may be one of the atmosphere's rare gases.

CF_4 is a very stable compound that behaves like an inert gas up to a temperature of about 2,000 °C. The presence of CF_4 in the atmosphere at a concentration of approximately 0.1 to parts per 10^9 (p.p.b.) was deduced by Gassman[1] from MS analyses of contaminant levels of CF_4 in high-purity krypton samples. Gassman suggested[1] that CF_4 was enriched from the atmosphere during the cryogenic preparation of high-purity krypton. The GC–MS analyses made at Harwell were conducted to determine whether CF_4 is indeed a common constituent of the ambient atmosphere, and if so at what concentration.

A pre-concentration technique was used to provide samples for GC–MS analysis. A glass U-tube equipped with Teflon stopcocks was immersed in liquid nitrogen and air was allowed to liquify until the tube was approximately two-thirds full. Clean helium was then bubbled slowly through the trap until the liquid air had evaporated. The trap was then removed from the liquid nitrogen and thermally equilibrated at room temperature. This created a positive pressure of helium in the trap containing enriched concentrations of the trace species present in the air at the time of trapping. Samples of the mixture were then simply taken off the side arms of the trap with a syringe and injected directly into the chromatographic column. The helium gas used in the enrichment process was cleaned before passage into liquid air by passing through 40 ft of stainless steel tube ($\frac{1}{8}$ inch outer diameter), immersed in liquid nitrogen. This effectively removed all CF_4 and Xe that may have collected in the liquid air trap in the evaporation process. Analysis of blanks made by passing helium through the cold empty trap for 30 min showed no signs of either CF_4 or Xe.

For quantification both ^{84}Kr (boiling point −158 °C) and ^{132}Xe (boiling point −107 °C) were measured directly in 5 ml air samples and in the cryogenic preparations. Essentially 100%

enrichments of ^{84}Kr and ^{132}Xe were obtained. Accordingly the high efficiency of the cryotrap for ^{84}Kr and ^{132}Xe bracketing CF_4 with its intermediate boiling point of −128 °C was taken to indicate that CF_4 was quantitatively enriched. Subsequent analyses measured only ^{132}Xe for use as an internal standard in the CF_4 analyses. The concentration of ^{132}Xe in the air is 23 p.p.b. determined from its isotope abundance of ~27% of a total xenon atmospheric concentration of 84 p.p.b. Accordingly its constant atmospheric concentration provided an excellent internal standard for determining the enrichment ratios of the samples studied.

Analyses were performed on a Hewlett-Packard 5700 series gas chromatograph fitted with a $\frac{1}{4}$ inch o.d., 3 ft glass column packed with 70–140 mesh Woelm alumina GSC-120. Column temperature was held at −20 °C to enrich the 10 ml injections of the cryotrap contents onto the head of the column. After elution of the air peak, at 2 min, the temperature was raised ballistically (>32 °C min^{-1}) to +50 °C. Helium purified by passage through liquid N_2 was used as the carrier gas to 40 ml min^{-1}.

The gas chromatograph was interfaced to a V.G. Micromass-16 mass spectrometer by a jet separator. Mass 69 (CF_3) was monitored as the major peak for the parent CF_4 species with a retention time of 3.2 min. ^{132}Xe was measured at 4.2 min.

A representative analysis of CF_4 and ^{132}Xe chromatographed from an enriched air sample from South Pole, Antarctica, is shown in Fig. 1. The peak heights of each compound were used for quantitation against a CF_4 calibration standard in air and the known atmospheric concentration of ^{132}Xe. The ^{132}Xe peak was used as an internal standard to determine the enrichment ratio obtained in processing the cryotrap. The gains of the output attenuation of the strip chart record are CF_4, $10^{-8} \times 10$ and ^{132}Xe, $10^{-5} \times 5$ A V^{-1}.

The concentration of CF_4 was determined in 21 analyses of 11 different ambient air samples representative of the environs around AERE Harwell, and three other air samples representing the South Pole, New Zealand and the Pacific Northwest. The results of our measurements of the concentration of CF_4 are shown in Table 1. The mean CF_4 concentration for 16 analyses of Harwell air is 63.6 ± 13.2‰ by volume. The mean of the other three air samples for five analyses is 64.4 ± 3.2 p.p.b. by volume. No significant difference between the two sample populations is indicated. The variability in the Harwell values is about equal to the variability obtained in repetitive and/or duplicate analyses. Accordingly the CF_4 concentration in the Southern Hemisphere and that observed for the Northern Hemisphere suggest no inter-hemispheric differences at the present level of precision of analysis.

At the same time as the CF_4 measurements of ambient air were made, two samples of volcanic emissions representative of a hot fumarole in the caldera of Mauna Loa (13,000 ft) and a much cooler vent on the north-east side of Kilauea at Iilewa (3,500 ft) were analysed. The two samples showed similar levels of CF_4 of 48.3 ± 2.5‰ by volume but at concentrations considerably lower than the level of 64‰ determined for the ambient air. The related halocarbon and other trace gas measurement data are given in Table 2.

The 25% lower level of CF_4 observed in the volcanic samples is consistent with the 17–27% lower fluorocarbon 11 and 12 levels typically observed in the Hawaiian volcanic emissions. This is interpreted to mean that the origin of both the fluorocarbon 11 and 12 and CF_4 is not from the gases being released from the fumarole's activity, but rather their presence represents entrainment of ambient air into the subterranean passages that is re-ejected into the atmosphere via the hot air plume in the chimneys associated with different volcanic vents. During the contact with the hot volcanic rocks some destruction of these materials has occurred as well as dilution. Previously Gassman had suggested that volcanic emissions may be a source of CF_4. This may still be correct as the Hawaiian volcanic emissions studied are not typical of the active magnetic gases released

during a volcanic eruption. Also the halogen concentrations in the Mauna Loa type of volcanic emission are much lower than the halogen content of the emissions from other types of volcanoes.

The direct industrial production of CF_4 is minimal—<10 tons yr^{-1}. Therefore, its dispersive use is not expected to be a significant source of CF_4. The only other documented source of CF_4 is the electrolytic alumina reduction furnace. However, the production of CF_4 in this industrial process is not continuous, rather it is restricted to 5–10 min periods per day as the alumina content of the cell approaches depletion[2,3]. Because of its sporadic nature, any estimate of CF_4 emissions from the alumina reduction process is subject to a very large spread in the amount of CF_4 produced and released to the atmosphere. Nevertheless, however speculative, we estimate that about 6×10^9 g yr^{-1} of CF_4 may be emitted from the world wide 1977 production of aluminium of 1.34×10^{13} g yr^{-1}. If this is the case, then the aluminium industry is not likely to account for all of the global atmospheric burden of CF_4, which at an average concentration of 65‰, approximates to 10^{12} g. More information is obviously needed to establish the true contribution of CF_4 from the aluminium industry, but it is equally obvious that other sources of CF_4 need to be found.

Support for this research was provided by the UK Department of the Environment, DOT-HAPP work order W1-78-3745-1, Biospheric Research Laboratory and NSF grants DPP77-23468 and ATM78-09711.

Trace metals in Antarctic snows since 1914

THE results of the variations of the concentrations of 12 elements including Pb, Cd, Cu, Zn and Ag in snow deposited from 1914 to 1974 at an uncontaminated site in East Antarctica are discussed here. As the composition of snow in central Antarctica is shown to be closely correlated to that in the lower atmosphere, this provides us with a valuable historical record of the composition of remote aerosols in the Southern Hemisphere. We find that Pb, Cd, Cu, Zn and Ag were already strongly enriched 60 yr ago (with respect to the composition of reference crustal and marine sources), and that both the concentrations and the enrichment factors observed in 1914 for these five elements are comparable to the present ones. This suggests that the present background atmospheric concentrations of Pb, Cd, Cu, Zn and Ag in the Southern Hemisphere are not strongly influenced by global pollution, but are related to natural phenomena, possibly volcanism.

A recent increase in studies of the chemical composition of tropospheric aerosols in remote areas has included data[1,2] from northern and southern regions, including the South Pole. Concentrations of heavy metals are found to be much greater than expected on the basis of the average composition of the Earth's crust and of seawater. We cannot determine whether this is due to man's increasing industrial activities by current atmospheric sampling programmes. However, we can determine the relative contributions to the composition of aerosols from natural and anthropogenic sources by analysis of impurities in successive layers of snow in polar ice sheets, as has been done for near surface layers of the Greenland ice sheet[3–6].

During the 1974–75 summer field season, 13 successive snow samples were collected from the surface to a depth of 5.35 m in a hand dug pit at Dome C (74°40′ S, 124°10′ E, elevation 3,240 m), which was at the time an uncontaminated site 600 km from the nearest scientific station and some 240 km from the nearest oversnow traverse. Samples were collected within a few weeks of the first aircraft landing at the site. The samples of the firn, about 0.7 kg each, were collected[7] by operators clothed in clean room garb, using Plexiglass tubes with screwed caps (inside diameter 8 cm, length 42 cm, rinsed in a class 100 clean room with ultrapure acids and water) pushed directly into the snow along a scoured pit wall. The tubes were then placed in double sealed polyethylene bags and kept frozen until the analytical stage. The samples were transferred by gravity directly into Teflon bulbs inside a class 100 clean room, for preconcentration[8] (×150) by non-boiling evaporation; this preconcentration procedure includes dissolving any solid particles by hot concentrated ultrapure hydrofluoric and nitric acids. Na, Mg, K, Ca, Fe, Al, Mn, Pb, Cd, Cu, Zn and Ag are then determined by graphite furnace atomic absorption (electrodless discharge lamps for Pb, Cd and Zn) in the clean room. The complete procedure was calibrated[8] by processing 80 synthetic standard solutions of various concentrations down to 10^{-12} g/g that overlapped the Antarctic snows concentration ranges. Contamination from the field Plexiglass sampling tubes was found to be negligible for all the 12 elements[7] by analysing ultrapure water used for an extensive rinsing of 'blank' field Plexiglass tubes. The overall analytical precision (atomic absorption and preconcentration process) calculated from the calibration curves using

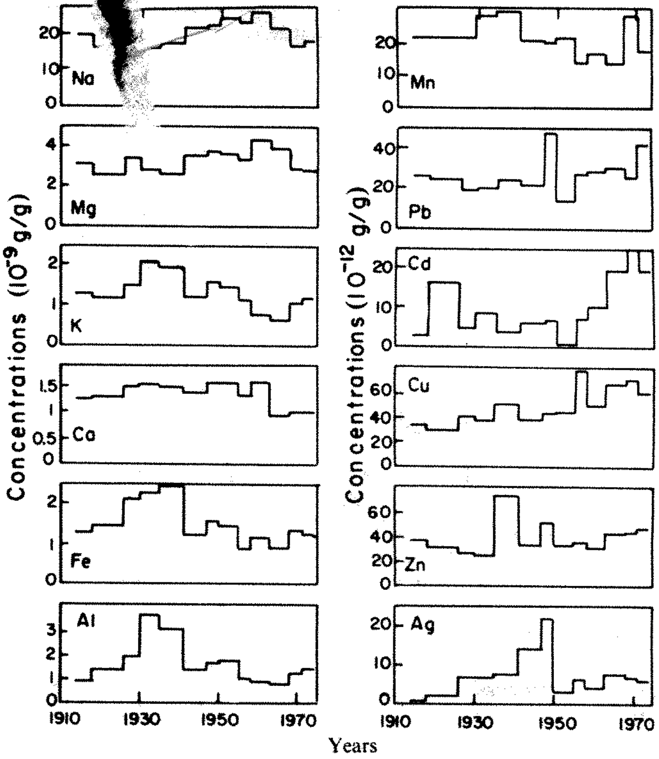

Fig. 2 Dome C, Antarctica: variations of the measured concentrations in snow between 1914 and 1974.

confidence limits of 95% is of the order of 10% (30% for Cd). All data are summarised in Table 1.

The age of the snow samples collected between the surface and 2.06 m has been determined in our laboratory by various independent techniques[9] including stratigraphy, stable isotope composition and radioactive fallout horizons from nuclear tests, which identify seasonal snow layers and make it possible to attribute specific dates to several characteristic horizons over the past 25 yr. Beyond 2.06 m, solely stratigraphic data have been used. The age of the samples ranges from 1974 to 1914, Table 1. The accuracy of these unpublished dating results (Petit, personal communication) is ±1 yr between the surface and 2.06 m (years 1974–55); it decreases then with increasing depth to ±5 yr at 5.35 m (year 1914).

The elements measured in this work can originate from three principal sources: the oceans, the continents and man's activities. The relative influence of these three sources at Dome C can be determined by analysing the correlation matrix of the 12 measured elements through principal components factor analysis[10,11] (FA). FA studies this correlation matrix by diagonalising it, solving it for eigen values and vectors which are linear combinations of the original 12 elements, and taking these eigen vectors as new reference axes. The results of FA are shown in Fig. 1 for the two eigen vectors $\mathbf{F}_1$ and $\mathbf{F}_2$ corresponding to the two highest eigen values; these two vectors account respectively for 40.6 and 23.5% of the sample set variance. They separate three groups of elements: Na (marine reference element) and Mg (top right); Al (crustal reference), Fe, Mn, K and Ca (left); Pb, Cd, Cu, Zn and Ag (bottom right). This suggests an oceanic source for Na and Mg, a crustal continental source for Al, Fe, Mn, K and Ca, and a third source, independent from the two others, for Pb, Cd, Cu, Zn and Ag, as previously found at South Pole Station[12].

It has been suggested[13] that in clean air conditions, the chemical composition of precipitations and of aerosols would be closely related. This is seen to be the case at the South Pole as shown by the data of Table 2. The two sets of data do not correspond to comparable time periods: this is probably unimportant as only weak seasonal variations of the concentrations are observed[10] in these areas, at least in snow, but for Na and Mg. The ratio of the concentrations measured in air (expressed in 10^{-12} g per standard cubic metre) to those measured in deposited snow (expressed in 10^{-12} g/g) range from 0.4 to 1 but for K and Cd for which slightly higher ratios are obtained. Although this relationship might be influenced by various parameters, it is unlikely that marked changes happened over the past century which was characterised by rather constant climatic conditions. The variations of the trace elements content of dated snow layers in central Antarctica can therefore probably be used to reconstruct the past variations of the aerosol content of the low troposphere. Variations in concentration of all 12 elements over the period 1914–74 are shown in Fig. 2.

At Dome C there are significant variations with time for all the elements. These variations are probably not linked with short-term changes such as seasonal effects[4,10], as each sample integrates at least 4 yr of snow accumulation. Generally speaking, concentrations in firn of 60 yr age are similar for all the elements to the present concentrations, except perhaps for Cu, whose concentrations increase slightly (×1.5) between 1914 and 1974. Apparently, therefore, the atmospheric concentrations of the measured elements have not increased markedly, despite significant variations, since 1914. We previously found[12] an increase of the concentrations of Pb, K, Zn and Ag (×2–3) and Cu (×6) in snow between 1950 and 1974 at South Pole Station. The present data obtained at Dome C confirm this increase between 1950 and 1974 for Pb, but the increase is less pronounced for Zn, Ag and especially Cu at Dome C than at South Pole Station; no increase is detected for K. This suggests that slight local contamination associated with operations at South Pole Station, which has been occupied since 1957, may have occurred for some elements.

The absence of an increase in the atmospheric concentrations of trace elements at Dome C between 1914 and 1974 suggests that they are not significantly affected by global pollution.

Historical records of some trace metals discussed here have already been published for Greenland in the Northern Hemisphere[3–6]. No trend was found for Hg [5] and Cd [4,6], while Pb [3,4] and Zn [4] concentrations were shown to have increased by a factor of two to three since the beginning of the century. There was no clear results for Cu [6]. Our results therefore indicate that industrial pollution has had no significant effect on the background composition of the atmosphere of the Southern Hemisphere, although it seems to have some effect on the background content of some heavy metals (Pb, Zn) in the Northern Hemisphere atmosphere. This is in good agreement with the fact that more than 90% of anthropogenic aerosols are emitted in the Northern Hemisphere[15], and that the Equator is a barrier for tropospheric aerosols.

The interesting features, shown in Fig. 2, are the high measured concentrations of Al, Fe, Mn and K (elements of crustal continental origin according to FA) between 1925 and 1940 approximately. This could be explained by an enhancement of the meridional circulation between 1925 and 1940 in the Southern Hemisphere, resulting in an increase of the transport fluxes of crustal material from mid latitude continents to Antarctica. We have no literature values on the historical variations of the circulation patterns in the Southern Hemisphere, but it has been suggested[16] that, in the Northern Hemisphere, they were different between this time period and the remaining other years of the 1900–68 period.

The variation with time of the enrichment factors with respect to bulk seawater (EF_{sea}) for Mg, and with respect to the mean crustal composition[17] (EF_{crust}) for K, Ca, Fe, Mn, Pb, Cd, Cu, Zn and Ag are shown in Fig. 3. The reference elements are respectively Na and Al. The precision is better than 20% for all the elements except for Cd (40%). Calculated EF_{sea} values are close to unity for Mg, confirming that the sea is the likely source for this element. EF_{crust} values near unity are obtained for K, Ca, Fe and Mn suggesting again a crustal continental source for all these elements.

On the other hand, high EF_{crust} values ranging from one to four orders of magnitude are observed for Pb, Cd, Cu, Zn and Ag. This supports the FA data showing an independent source for these last elements. For Pb, Cd, Cu and Zn, the EF_{crust} decrease more or less sharply from 1914 to 1930; they remain then almost constant between 1930 and 1950, and then increase from 1950 to 1974. There are large variations for Ag, but the mean values between 1914 and 1930 are not very different from those between 1950 and 1974. It seems that despite large variations with time, the enrichments factors for the heavy metals are as high in 1914 as the ones observed in 1974. This again suggests that these high enrichments observed for heavy metals in Antarctic snows, and therefore for the Southern Hemisphere background aerosols, are not significantly influenced by global pollution, but are linked with natural phenomena.

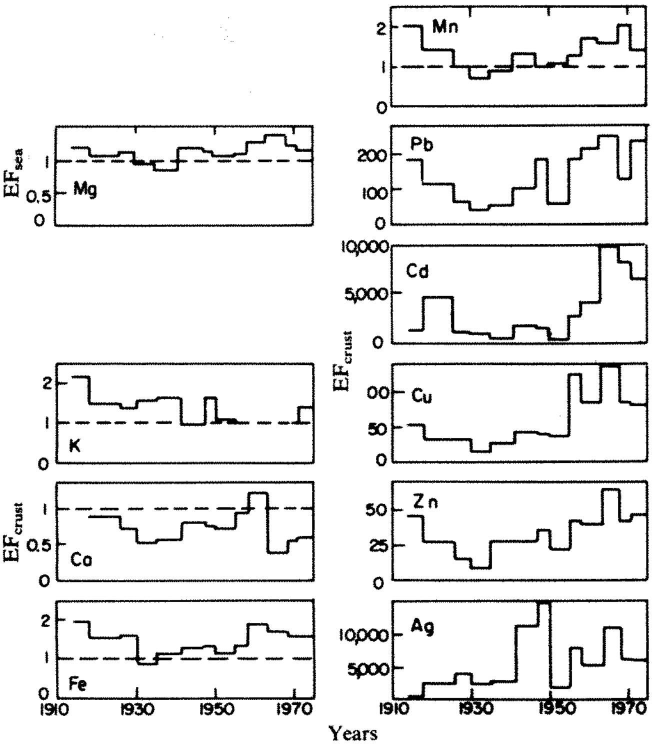

Fig. 3 Dome C, Antarctica: variations of the enrichment factors between 1914 and 1974.

Table 2 South Pole station: comparison of the chemical composition of deposited snow with that of local atmospheric aerosols

Element	Concentrations Aerosols* (10^{-12} g/standard cubic metre)	Snow† (10^{-12} g/g)
Na	3,300 ± 1000	7,700 ± 140
Mg	720 ± 430	1,300 ± 130
K	680 ± 140	370 ± 70
Ca	490 ± 200	510 ± 190
Fe	620 ± 230	760 ± 90
Al	820 ± 380	1,070 ± 250
Mn	13.5 ± 3.5	18 ± 4.5
Pb‡	27 ± 10 76 ± 40	40 ± 11
Cd	18 ± 13	3.8 ± 2.8
Cu	29 ± 17	47 ± 1.4
Zn	33 ± 20	6.8 ± 7.8
Ag	3.4 ± 3.6	5.5 ± 0.07

* From ref. 14. The results are the average of five sampling periods of nine days between 16 December 1974 and 4 February 1975. The error listed is the standard deviation derived from the dispersion of the concentrations for the five sampling periods.

† From ref. 10. The results are the mean concentrations measured in four snow samples integrating the years 1973 and 1974. The error listed is the standard deviation derived from the dispersion of the concentrations for the four samples.

‡ The two values for aerosols correspond to two sets of samples collected by using different sorts of filters (see ref. 14).

The possible natural sources or mechanisms responsible for these very important enrichments of heavy metals are still being discussed[1,2,4,18]. The emission into the atmosphere of heavy metals from the ocean surface microlayer[19,20] and from plants[21,22] has been described and could be very significant. However, the most likely source could be volcanism. Little information is available on the chemical composition of volcanic aerosols, but it seems that they are strongly enriched in Pb, Cd, Cu, Zn and Ag[23,24], with enrichment factors close to those determined at Dome C[23,24]. The background fallout fluxes of these five elements for the Southern Hemisphere calculated[25] from our Dome C data (by assuming as a first crude approximation an homogeneous deposition pattern) correspond approximately to emission fluxes[24] from about 10 volcanoes similar to Mt Etna in Italy. Moreover, the historical record of the stratospheric burden of volcanic aerosols[26] shows that after decreasing from 1900 to 1920, and being low between 1920 to 1945, this burden increased after 1945. These time variations are similar to observed changes of concentrations shown in Fig. 2 and enrichment factors shown in Fig. 3 for Pb, Cd, Cu, Zn, but not for Ag. Although it has been shown[27] that remote volcanic aerosols can reach the Antarctic ice cap, more detailed information on volcanic sources (chemical composition, fluxes) and analyses of snow samples covering a much longer time period including more particularly the years 1850–1910 which were characterised by the two powerful eruptions of Krakatoa (1883) and Santamaria (1903) are needed to confirm if volcanoes are really responsible for the past and present day atmospheric concentrations of heavy metals.

Gerontology of the Allende meteorite

IN the Allende meteorite several elements are found to have an isotopic composition that cannot be due to radioactive or spallation or fractionation processes[1]. These isotope anomalies are mostly confined to white inclusions enriched in refractory elements[2] (Ca–Al-rich inclusions) and are thought to be introduced into the Solar System by precondensed grains[3]. We have previously reported an anomalously high K–Ar age of a composite sample of five white inclusions from the Allende meteorite[4]; no direct verification of this lone-standing result of 4,800 Myr was possible because, with the exception of a small chip of one of the inclusions used for a thin section, the material was fused in the ^{40}Ar–^{39}Ar experiment. We therefore began a search for old material in other Ca–Al-rich inclusions. Three different samples from a new type of inclusion proved to be no older than most of Allende's constituents, 4,510 Myr (ref. 5). A small white inclusion gave a well developed ^{40}Ar/^{39}Ar plateau over almost the entire ^{39}Ar release, with an age of 4,500 ± 20 Myr (ref. 6). We report here on the ^{40}Ar–^{39}Ar analysis of two further coarse-grained Allende inclusions that showed ages in excess of 4,550 Myr.

In the most widely accepted theory a supernova triggered the collapse of the solar nebula[3,7] and the anomalously high ages would be due to an enhanced ^{40}K/^{39}K isotopic ratio produced in the explosive carbon burning shell of the supernova[7]. In another, controversial interpretation these ages could have chronological significance, as here the presolar grains are relicts from various old stellar nucleosynthetic and condensation processes unrelated to the formation of the Solar System[8-10].

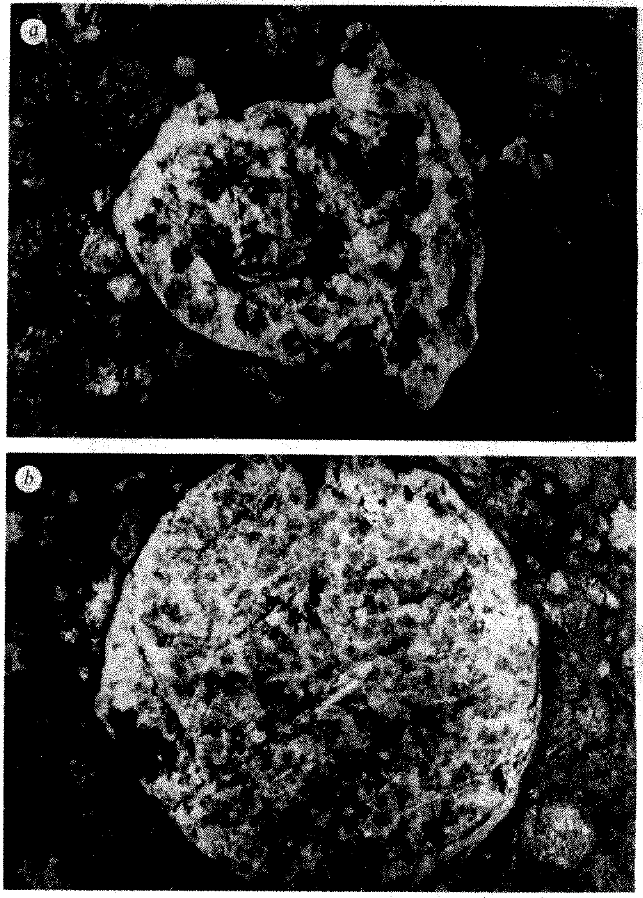

Fig. 1 Photograph of two Allende inclusions from which chips were taken for ^{40}Ar–^{39}Ar analysis. (Sample 17(*a*); sample 18(*b*)).

Sample 17 was a 15.1 mg interior chip of an irregular white cavernous inclusion (Fig. 1*a*). Binocular inspection revealed the presence of at least three different mineral phases: dark grey and clear crystals (up to 1 mm) were closely packed in a sugary white matrix material. The inclusion was surrounded by an 80–100 μm wide, extremely fine-grained rim locally enriched in spinels.

Sample 18 was a 40.9 mg interior chip of a round white inclusion (Fig. 1*b*) with a diameter of ~11 mm, which also had a core and a rim (0.2 mm). The core consisted of dark crystals (0.5 mm) embedded in a light grey crystalline matrix. Microscopic investigation showed a mineral composition typical of type B inclusions[2]. The core of the inclusion consists of prismatic xeno- and hypidiomorphic clinopyroxene crystals (80 μm–1 mm, majority 200–500 μm). Melilite and anorthite are subordinately present, melilite as xeno- or hypidiomorphic, sometimes elongated grains (350 μm–2 mm), anorthite as lath-shaped twinned crystals. Spinel occurs either as hypidio- and idiomorphic isolated grains (2–25 μm), poikilitically enclosed in pyroxene, melilite, and anorthite, or as round aggregates (30–160 μm) of minute crystals. Inclusions of opaque minerals dispersed in pyroxene and melilite are common. The rim of the inclusion, 80–100 μm wide, consists of extremely fine-grained crystalline material, partly enriched in spinels (5–15 μm). Some pyroxene crystals show deformation lamellae. More detailed mineralogical as well as chemical studies of these inclusions are in preparation.

The irradiation, argon extraction, purification, and data

0028–0836/79/0277—0554$01.00

analysis procedures are identical to those previously published[11], except that the atmospheric argon was not removed before the ^{40}Ar–^{39}Ar experiment by preheating.

The results of the argon analysis are given in Table 1, at the same stage of data reduction as in ref. 11. For the apparent ages (I), a correction for trapped ^{40}Ar with the conventional ratio $(^{40}\text{Ar}/^{36}\text{Ar})_{\text{trapped}} = 1 \pm 1$ was applied. To take into account atmospheric contamination, minimum ages (II) were calculated after subtraction of $295.5 \times {}^{36}\text{Ar}_{\text{trapped}}$ (that is, in the atmospheric ratio) from ^{40}Ar. These ages are the basis of our present discussion. Age spectra are shown in Fig. 2.

Absolute concentrations are 155 p.p.m. K, 12% Ca and 70 p.p.m. K, 14% Ca for sample 17 and 18, respectively. In the reactor irradiation ^{38}Ar is produced from Cl present in small amounts[12] and thus nominal ^{38}Ar/Ca exposure ages in these inclusions are too old compared with the known cosmic ray exposure time of Allende of 5 Myr (ref. 13). Note, however, that ^{38}Ar from Cl is small in the 1,130–1,380 °C fractions of sample 17, which yields a weighted average exposure age of 3.9 Myr (production rate 2.8×10^{-3} ccSTP $^{38}\text{Ar}_{\text{C}}$ per g_{Ca} Myr).

The age spectra obtained from both samples are rather similar. Taking the minimum apparent ages, we observe broad plateaus extending over the first 50–60% of ^{39}Ar released. At high extraction temperatures, beginning at 1,070 and 1,300 °C, respectively, the apparent ages become older by about 400 Myr, compared with the plateaus.

The two-step patterns of the age spectra are reflected in the K/Ca variations. K/Ca of the plateau fractions is relatively stable, most pronouncedly so in sample 17, indicating that over a wide temperature regime the same mixture of phases is degassed. Low K/Ca ratios at higher temperatures are associated with high ages, the opposite of what is expected from ^{39}Ar recoil[14].

Two-step ages patterns have also been previously encountered in lunar highland breccias[11,15,16]. There the significance of both parts of the spectra had been confirmed by spotwise laser ^{40}Ar–^{39}Ar dating[17,18]. The difference between the results of those lunar studies and of Allende samples 17 and 18 is the >4,500 Myr age of the latter and the 'normal' ages of the former. In addition to the samples reported here, we irradiated and analysed a sample of lunar highland breccia 73215, 170, 6, a pink spinel-bearing troctolitic clast (O. B. James, personal communication), which below 1,050 °C yields a plateau age of 3,940 ± 70 Myr in agreement with the formation age of the breccia of 3,870 Myr (ref. 19). At 1,400 °C half of the ^{39}Ar is released with an apparent age of 4,450 ± 40 Myr. This age is about the same as obtained for other early lunar differentiates[15,20]; it may even be the oldest one. The age of this clast fits perfectly into the chronological framework established for breccia 73215 (refs 11, 19, 21). It also demonstrates that the >4,500 Myr ages of our two Allende inclusions are not due to some kind of a calibration error. Instead, the new results support the 4,800 Myr K–Ar age previously reported. The nominal K–Ar ages of samples 17 and 18 are 5,120 ± 60 Myr and 5,080 ± 50 Myr, and the plateau ages are 4,980 ± 60 Myr and 4,900 ± 30 Myr, respectively. A high-temperature phase must be responsible for the still higher apparent ages of the 1,130 or 1,300 °C fractions, averaging 5,400 ± 100 Myr.

The ratio of 'excess' ^{40}Ar (over that produced since 4,550 Myr) to K is 0.033 ccSTP per g for both samples. It is unlikely that this excess ^{40}Ar migrated from the K-poor matrix (200 p.p.m. Jessberger *et al.*, in preparation) into the inclusions. Not only is there no precedent for such a migration, but it would also have to occur to precisely the right degree to balance the different K concentrations.

It has long been argued that the isotopic anomalies and some other peculiar features of the Ca–Al-rich inclusions were introduced into the Solar System by presolar grains[8,22–25]. Two principal origins of the presolar grains have been proposed. According to Clayton[9], they represent interstellar dust from various sources. Such dust, if not outgassed, should have a mean K–Ar greater than that of the Solar System. In that picture[10], the anomalously old ages are real and indicate the survival of

Table 1 Amounts and isotopic composition of Ar released from two coarse-grained white inclusions of Allende after experimental corrections. Apparent ages II are calculated after subtraction of $295.5 \times {}^{36}\text{Ar}_{\text{T}}$ from ^{40}Ar to account for atmospheric contamination

non-degassed K-bearing grains 'from the beginning of the Universe' through the turbulences of the Ca–Al-rich inclusion-forming processes. Irradiation of the presolar grains with cosmic ray particles before formation of the Solar System is proposed by Clayton's model. The absence of large amounts of spallation ^{38}Ar, however, does not necessarily invalidate this model, as the size of interstellar grains[26] is not sufficient to stop (and hence trap) the recoiling spallation products within the boundaries of the grains.

According to the second model, which is not in all aspects contradictory to the first, the presolar grains condensed in a late supernova that triggered the collapse of the solar nebula[3,7]. In this model apparent K–Ar ages can result from an isotopic enhancement of ^{40}K. Note here that K–Ar ages are usually not based on ^{40}Ar/^{40}K ratios, as the principle of the method would require, but in the case of the ^{40}Ar–^{39}Ar method they are calculated from ^{40}Ar/^{39}K ratios, which are converted to the proper ratios by assuming that the sample has the normal Solar System ratio of ^{40}K/^{39}K. As calculated by Cameron and Truran[7], the explosive carbon burning phase of supernovae produces a ^{40}K/^{39}K ratio that is 70 times the average Solar System ratio 4,600 Myr ago.

Other anomalies like the ^{48}Ca enhancement[27] are also attributed to the explosive carbon burning phase as are FUN anomalies[28,29]. An apparent K–Ar age of 5,100 Myr corresponds to a ^{40}K enrichment of 35%, whereas an age of 5,400 Myr as measured in the high temperature fractions of samples 17 and 18, requires a 60% enrichment of ^{40}K relative to the Solar System value of ^{40}K/^{39}K. These large enrichment factors, however, do not imply extraordinarily large numbers of extra ^{40}K atoms. The magnitude of this anomaly is only 1/50 of the excess ^{48}Ca atoms in inclusion EK 1-4-1 (ref. 27).

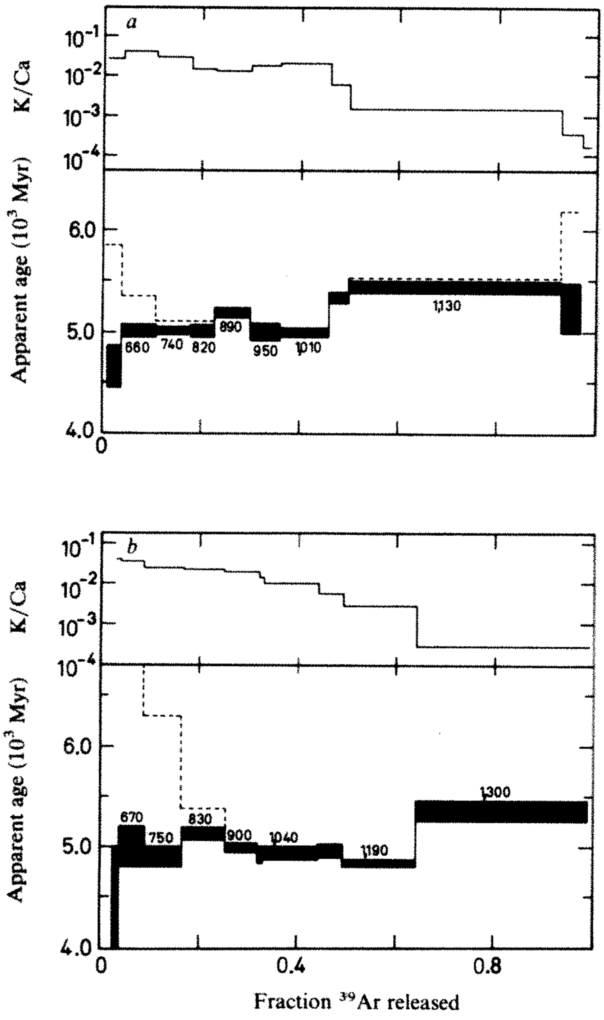

Fig. 2 K/Ca and apparent age spectra of two white Allende inclusions. The broken lines in the age spectra represent the apparent ages without correction for atmospheric contamination.

Unfortunately, the possible presence of a ^{40}K isotopic anomaly does not clearly distinguish between the two models, as both allow for ^{40}K enhancements. However, Clayton[10] predicts an additional ^{41}K anomaly in his model. This letter does not attempt to discuss the merits or problems of both models.

Up to now three Ca–Al-rich inclusions have been analysed for their K isotopic composition and have been found to have normal ratios[30,31]. These negative results, however, do not preclude samples 17 and 18 from having anomalous K. Note that so far, FUN anomalies of Mg, O (refs 28, 32) have only been encountered in two inclusions of Allende out of some 50 searched. Thin section studies of the parent inclusion of sample 18 revealed the peculiar feature of magnetite preceding the iron-phase condensation (A. El Goresy, personal communication). Samples 17 and 18 may represent new examples of presolar FUN material.

The experimental verification of gas retention ages older than the accepted age of the Solar System in itself should not be interpreted as evidence for the survival of presolar grains—although the 'ages' are highly suggestive—until the carrier material of the extra ^{40}Ar is identified and further isotopic evidence obtained.

We thank E. Anders and T. Kirsten for useful discussions, and A. El Goresy for new mineralogical results of one of our samples.

Continental geotherms during the Archaean

PRESSURE and temperature data from Archaean terrains have been used to test whether heat production during the Archaean at about three times the present rate resulted in correspondingly steeper continental geothermal gradients[1–6]. The rocks considered here lie mostly in the range of medium pressure metamorphism, recording pressures of 7–13 kbar at temperatures of 600–900 °C (ref. 2). These pressures, with the underlying, normal, thickness of crust imply great thickening of continental crust during the Archaean.

0028-0836/79/0277—0556$01.00

Although these temperatures and pressures may record conditions during a phase of crustal generation—presumably dominated by igneous activity—the time for thermal equilibration of such a province is short (~50 Myr: for example, oceanic lithosphere) and unless the ages of the mineral parageneses can be tied in with this accuracy to phases of crustal generation, the crustal thickening and *P–T* data may result from a later and quite separate metamorphic episode.

By analogy with the behaviour of Phanerozoic terrains, most of the exhumation of these rocks must have occurred in the first few 100 Myr after the episode of crustal thickening. In these circumstances a *P–T* estimate represents only a point in *P–T*-time space and it is of little use, therefore, to try to fit it to any steady-state geotherm[7,8], particularly to one for normal crustal thickness.

However, it will be shown that if the time-dependent nature of the geotherm is accounted for, these data are still useful in that they give an upper limit to the geothermal gradient in thickened Archaean crust[5,6]. This is self-evident if the overthick crust was produced by magmatic intrusion, but it needs to be demonstrated if the thickening was not accompanied by extensive magmatism.

In the first case, the intrusive terrain would have cooled rapidly so that the *P–T* data reflect closely the magma-steepened geotherm, even when erosion is rapid[7]. If, however, the overthick crust was produced by over- or under-thrusting this will not necessarily be true. The common feature of these forms of crustal thickening is the lateral injection of cool crustal material, rather than the vertical emplacement of hot fluid. This results in the establishment of geotherms with dT/dP less than equilibrium ones, and their persistence for several tens of Myr (ref. 9); similar conditions apply if the overthick crust is produced by rapid sedimentation.

Erosion can considerably steepen the geotherm, however, and this, with continuing movement towards equilibrium during erosion, may mean that rocks buried deeper than about 30 km will not begin to cool until they have been decompressed by several kbar (refs 7, 10).

This point is demonstrated in Fig. 1 for two hypothetical terrains in which there is a linear gradient with the rock considered (initially buried at 40 or 60 km) at 900 °C. These profiles are then eroded at a linear rate[11] so that the rocks reach the surface in 50 or 200 Myr. The *P–T* paths for these rocks are shown in Fig. 1; when the rock is exhumed from 60 km between 80 and 90% of its cooling occurs in the last 30 km of its ascent and when it is exhumed from 40 km, the last 20 km of ascent shows 70–85% of the cooling. The portions of the *P–T* paths characterised by nearly isothermal decompression would be extended to lower pressures if there were radiogenic elements in the pile, as heating would continue during the ascent (see refs 7, 10). Also plotted in Fig. 1 are *P–T* data for the metamorphism of Archaean granulites summarised by Tarney and Windley[2]; a mean crustal density of 2.85 Mg m^{-3} is assumed in converting pressures to depth.

If the initial geotherms (dotted lines in Fig. 1) represent thermal profiles at, say, 70% of the temperatures which would be supported at equilibrium, then the dashed lines (E) show this equilibrium profile; probable *P–T* data from these rocks would lie close to (40 km burial) or to the high temperature side (60 km burial) of these equilibrium profiles. These arguments suggest that, whether the Archaean *P–T* data result from thickening of the crust by magmatism or from compression of cooler crustal material, they almost certainly represent temperatures as high as, or higher than, those which could be maintained at equilibrium in the thickened Archaean crust.

To estimate a 'normal' Archaean continental geotherm from the *P–T* data, thermal profiles for the thickened crust are calculated. It is assumed that a quantity of radiogenic heat production q_A, is distributed—either uniformly, or exponentially decreasing with depth on a scale length of 10 km—through the burden overlying the rocks which now yield the *P–T* data. The temperatures are sustained by this heating and a deep-seated contribution, q_*, from the lower portions of the crust and the mantle. The conductivity, *K*, is assumed constant throughout. A temperature of 900 °C at 40 km is taken as representative of the granulite *P–T* data; from the arguments given above this temperature is likely to be no lower than the equilibrium temperature at that depth in the overthick crust.

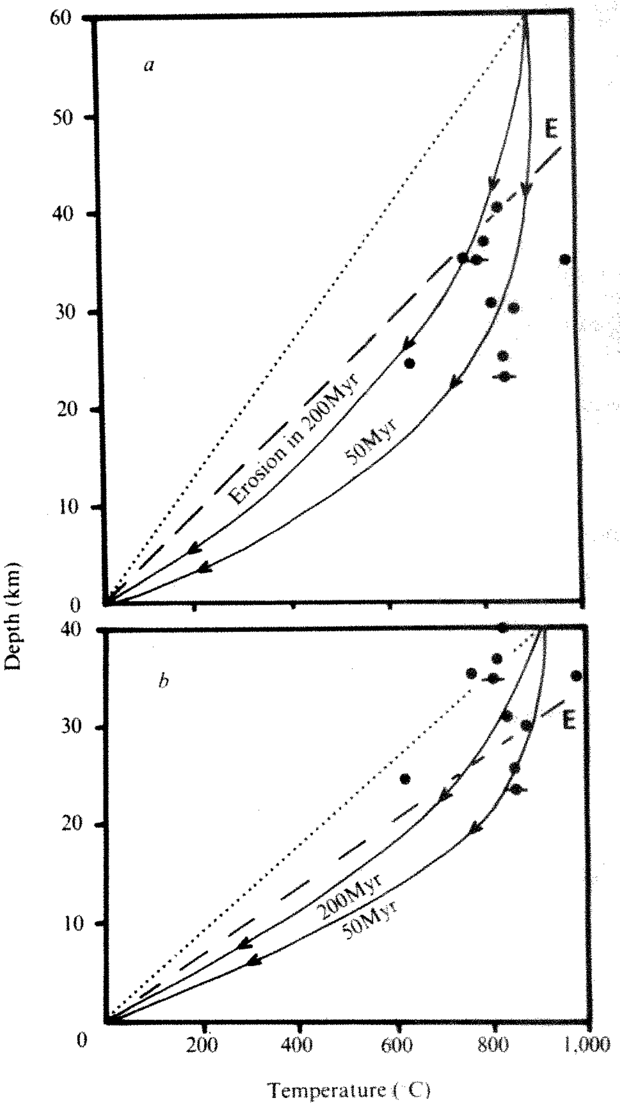

Fig. 1 *P–T* paths for rocks buried at depths of 60 km (*a*) and 40 km (*b*) in terrains of initially uniform thermal gradient such that they are at 900 °C at these depths. The rocks are subsequently exposed by erosion at a uniform rate over 50 or 200 Myr. Temperatures are calculated from Carslaw and Jaeger[11]. ● Indicate *P–T* estimates from Archaean terrains[2]; pressure and temperature ranges are plotted at their mid-points; and ● indicate that the pressure estimates are minima. Dotted lines (E) are 'equilibrium' geotherms if initial gradients represent only 70% of equilibrium temperatures.

An upper limit on the mantle contribution to Archaean continental geothermal gradients may be obtained by assuming that these temperatures were maintained without the help of radiogenic heating in the crust. The average crustal thermal conductivity is unlikely to have been greater than 4 W m^{-1} K^{-1} and this yields a limit of 90 mW m^{-2} for the Archaean mantle contribution to surface heat flow. In these conditions the temperature at the base of 35-km thick crust would be around 800 °C.

The heat production distribution in the overburden to the rocks preserving Archaean *P–T* data is, naturally, indeterminable and no more rigorous limit may be placed on q_* from these data. However, a plausible lowest limit on the radiogenic heat production in Archaean continental rocks may be obtained from measurements on the Th- and U-depleted pyroxene granulites from Australian Archaean terrains[12] and from measurements on high grade rocks in the Canadian Shield (see ref. 13). These rocks, after allowance for the decay of heat producing elements since the Archaean, would generate at least 1 μW m^{-3}, or a total of 40 mW m^{-2} through 40 km of overburden.

Table 1 shows the value of q_* required to maintain 900 °C at 40 or 60 km for a given value of q_A-distributed exponentially or uniformly through the 40 or 60 km of cover. Crustal radiogenic heat production at 40 mW m^{-2} over 40 km of cover requires q_* of 70–80 mW m^{-2}; some of this must come from the subjacent crust and if the estimate of 1 μW m^{-3} for heat generation in the Archaean continental crust is reasonable, this portion would be 20–30 mW m^{-2}.

Lower estimates of q_* would be obtained if it could be shown that exhumation from more than 40 km was responsible for the generation of the P–T data under discussion. Table 1 shows that q_* of 40–60 mW m^{-2} is required for the conditions described above if the rocks originated at 60 km rather than 40 km. Such rocks would follow the kind of P–T–t path of Fig. 1a and would perhaps show a record of progressive metamorphism during the early part of the path, when decompression was nearly isothermal.

Table 1 Values of q_* required to sustain temperatures of 900 °C at 40 and 60 km for different values of K and q_A (see text)

q_A (mW m^{-2})	Depth of burial 40 km			Depth of burial 60 km		
	Conductivity (Wm^{-1} K^{-1})					
Heat generation distributed uniformly	2	4	6	2	4	6
0	45	90	135	30	60	90
20	35	80	125	20	50	80
40	25	70	115	10	40	70
60	15	60	105	—	30	60
80	5	50	95	—	20	50
Heat generation distributed exponentially	2	4	6	2	4	6
0	45	90	135	30	60	90
20	40	85	130	27	57	87
40	35	80	125	23	53	83
60	30	75	120	20	50	80
80	25	70	115	17	47	77

These lower estimates of q_* would result in temperatures of 400–700 °C at the base of 35 km thick crust after the overburden was removed.

In conclusion, P–T data from high grade Archaean terrains represent temperatures reached during the exhumation of the rocks from an overthick crust and are probably not lower than equilibrium profiles for this thickened crust. At present the best upper limit which may be placed on the heat flow from the Archaean mantle from these data is 2–3 times present-day sub-continental values, and in this respect the P–T data offer no improvement in constraints of Archaean geothermal regimes over those from general observations of continental integrity in the Archaean: if a craton was formed of rocks of low radiogenic heat production and high conductivity, the base of its crust need not have approached melting temperatures even with mantle heat flow of 90 mW m^{-2}. On the other hand, mantle heat flow this high is not demanded by the observations; the P–T data could well represent a thermal regime in which the heat flow from below the continental crust was 40 mW m^{-2} or less.

It would be possible to lower the upper bound on Archaean continental geothermal gradients if reliable information were obtained on the distribution of heat-producing elements in the Archaean crust and on the P–T-time paths followed during the exhumation of high grade Archaean rocks.

The lower geothermal gradients permitted by the P–T data would be consistent with the view of Archaean tectonics in which the continental thermal regime was similar to that of present day and most of the additional heat was lost from the Earth's interior by a faster rate of creation of oceanic lithosphere[1,6].

I thank S. W. Richardson, E. G. Nisbet and B. Parsons for helpful comments, and the NERC for a research fellowship.

Uranium series dating of travertine from archaeological sites, Nahal Zin, Israel

AT present, absolute dates of occupation can readily be determined for prehistoric sites no older than about 40,000 yr BP using conventional ^{14}C techniques. Ages of older sites can be obtained with the K–Ar method, but only where volcanic deposits are interstratified with the archaeological deposits. The majority of Middle and Lower Palaeolithic sites contain no volcanic deposits. However, many of these sites are associated with synchronously deposited beds of calcium carbonate, occurring either as tufa mounds left by now extinct springs, or as layers of travertine (speleothem) in the mouths of formerly inhabited caves. We show here that such calcareous deposits can be dated by the ^{230}Th–^{234}U method, as long as they are relatively impermeable and free of detritus; ages in the range 5,000–400,000 yr BP are obtainable with a precision of 5–10%. When the carbonate is deposited, it invariably contains traces of uranium but essentially no thorium. Its age can be obtained from the extent to which ^{230}Th has grown into radioactive equilibrium with its parent ^{234}U. The technique of radiochemical analysis is given in ref. 1. The ^{230}Th–^{234}U method has been found to be less reliable for the dating of molluscs[2]; although it has also been applied to the dating of bones[3], the method has often yielded contradictory results, probably attributable to continuous diffusion of radionuclides through the bone during burial[4]. Some permeable, very fine-grained tufas have also given poor results in earlier studies[5]; however, careful choice of dense, impermeable, coarsely crystalline travertines generally yields dates that are mutually consistent and coherent with other geochronological tests[6].

We have applied this method to the dating of travertines found in association with artefacts of Middle and Upper Palaeolithic typology from sites in Nahal Zin in the north-central Negev Highlands, Israel. These open-air sites have been described by Marks *et al.*[7]. Lying on the floor of Nahal Mor (Fig. 1) is a large block of travertine in which there occurs a layer of artefact-bearing breccia. The artefacts include a few blades, flakes and a single blade core. The block has evidently fallen from a massive deposit of travertine seen clinging to the steep wall of the canyon about 30–35 m above the present valley floor. The blade core is particularly interesting because it exhibits hard hammer technique, an absence of edge regularisation, platform faceting only on the margin adjacent to the face of the core, and the removal of sizeable blades. These artefacts and the core in particular resemble material found in level 4 of site Boker Tachtit (D 101)[8] located in an alluvial terrace ~1.8 km downstream from the travertine block. Artefacts from this site represent the transition from Middle to Upper Palaeolithic typology. Charcoal from level 1 of site D 101 gave ages of >45,500, >35,000 and 45,000±2,400 yr BP; the stratigraphy of the site suggests that there is very little difference between the ages of levels 1 and 4.

Travertine samples from above and below the breccia layer exhibit very uniform $^{234}U/^{238}U$ ratios and uranium concentrations (Table 1), suggesting deposition over a relatively short time. There is no significant difference between the ages of samples from above and below the breccia stratum; pooling all the data, we conclude that the artefacts were deposited at 46,500±2,900 yr BP. This agrees satisfactorily with the ^{14}C estimates at D 101. Another adjacent fallen block of travertine gave an age in the same range. The alluvial terrace on which site Boker Tachtit was deposited, although largely removed by down-cutting of Nahal Mor, can be traced up the canyon to a point 20–30 m below the travertine mass from which the dated blocks must have fallen. Water from this now inactive spring may have been used by the occupants of Boker Tachtit, who chanced to leave the artefacts found embedded in the travertine.

About 5 km to the south-east, near the head of the Nahal Aqev (Fig. 1), lies a dissected mound of travertine marking the site of a former spring (Fig. 2). A layer of colluvial sediment interlaminated between the two outermost layers comprising this travertine mound contains several artefacts of Levallois technique[9]. They resemble artefacts found in site Nahal Aqev (D 35), 150 m NNE from the fossil spring. The artefacts from site D 35 are ascribed to the early Mousterian[10] and resemble Copeland's[11] Levantine Mousterian phase 1. These artefacts

‡ See Fig. 2 for location of layers A to E.

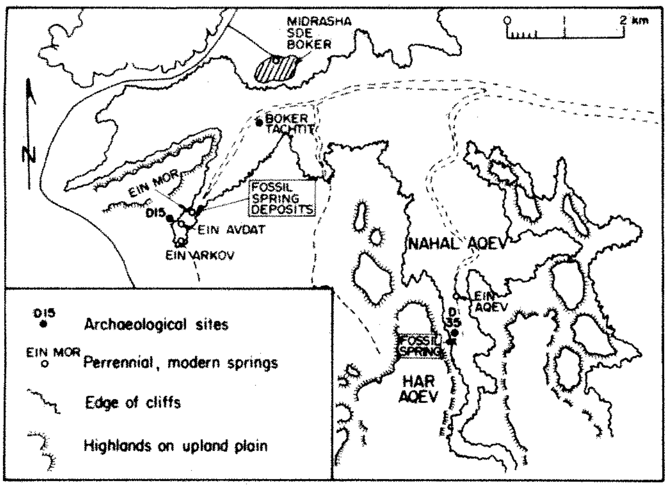

Fig. 1 Map of Nahal Zin showing locations of dated sites. Nahal Mor is the canyon in which Ein Mor and Ein Avdat are located.

also closely resemble the lithic technology of site Rosh Ein Mor (D 15), situated on the canyon rim above Nahal Mor.

The lowest layer of the travertine mound (Fig. 2A) was deposited 258,000 ± 66,000 yr BP, whereas three dates from layer B give an average age of 211,000 ± 19,000 yr BP. Layer C is undated. From layer D, two samples were obtained, one with an apparent age of 85,000 ± 10,000 yr BP (including a small correction for common ^{230}Th) and another (76NZ1) giving an age of 74,000 ± 5,000 yr BP. Unfortunately, both the artefact-bearing layer and the top layer (E) are too heavily contaminated with limestone fragments to permit dating. The artefact-bearing layer, which seems stratigraphically to be either of the same age or slightly younger than layer D, was therefore deposited at about 80,000 ± 10,000 yr BP. We infer that this was the time of occupation of site D 35, the location of which was presumably determined by the proximity of the spring[12]. The site may have been abandoned when flow from the springs ceased.

Further downstream in Nahal Aqev, the active spring of Ein Aqev is now depositing travertine on the steep walls of a box canyon. Older deposits a few metres downstream on the west side of the canyon mark earlier stages in the headward recession of the canyon. A sample from the surface of these deposits (76NZ8) shows that the spring was active 12,200 ± 700 yr BP; from the thickness of the deposits we infer that deposition started a few thousand years before that date, ~15,000 yr BP. This was close to the time of occupation of the nearby Upper Palaeolithic site D 31 (Ein Aqev), ^{14}C-dated at from 18,000 to 17,000 yr BP[13].

These results, as well as providing the first absolute date for the early Levantine Mousterian culture, demonstrate the potential of ^{230}Th/^{234}U dating of travertine in establishing an absolute time scale in archaeology.

Research was supported by grants from the National Geographic Society and the National Research Council of Canada. The archaeological and geological studies related to this paper were carried out under NSF grants GS-2860X1 and GS-42680.

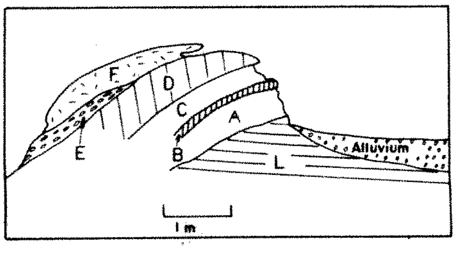

Fig. 2 Cross-section of fossil spring mound in Nahal Aqev. Layers A to D: travertine; layer E: colluvium containing Levallois flakes; layer F: travertine containing abundant limestone clasts; L: limestone bedrock.

Phylogeny and palaeobiogeography of hadrosaurian dinosaurs

MOST geologists agree on the placement of the continents at the end of the Cretaceous. Palaeobiologists, however, hold divergent opinions[1,2]. Some workers connect South America to Africa, some connect it only to North America, while others isolate South America totally. New evidence from vertebrate palaeontology suggest that a substantial land connection between North and South America existed 85–100 Myr ago which facilitated the passage of many terrestrial vertebrates between the continents, including large herbivorous dinosaurs. Specimens of hadrosaurian dinosaurs, collected in the first half of the present century, have now been used to reanalyse not only the palaeobiogeography but also the classification and phylogeny of this group. I report here the first solid evidence of an extensive land connection for large terrestrial vertebrates of this sort between North and South America at the end of the Cretaceous.

Hadrosaurs were the most diverse and abundant late Cretaceous, terrestrial vertebrate herbivores. In most cases they seem to have comprised up to 75% of the biomass in local faunas[3], according to recovered fossil samples. Their remains can be found in every Laurasian continent and also in South America. Because most specimens are represented by post-crania alone, and most workers believe that hadrosaur post-crania are not diagnostic, it has been almost impossible to map the distribution of sub-familial taxa. It is now possible, especially with pelvic elements, to identify a genus on the basis of a single element[4]. With this new information, previously named taxa can be rediagnosed, isolated elements from all over the world can be identified, and Cretaceous hadrosaurian palaeobiogeography can be reanalysed.

An accurate, useful phylogeny must include all valid taxa from all geological ages and all localities. Previous hadrosaur phylogenies have been based on North American data only[5,6]. My new phylogeny (Fig. 1) includes all forms at the generic level and recognises two subfamilies, the Hadrosaurinae and the

0028–0836/79/0277—0560$01.00

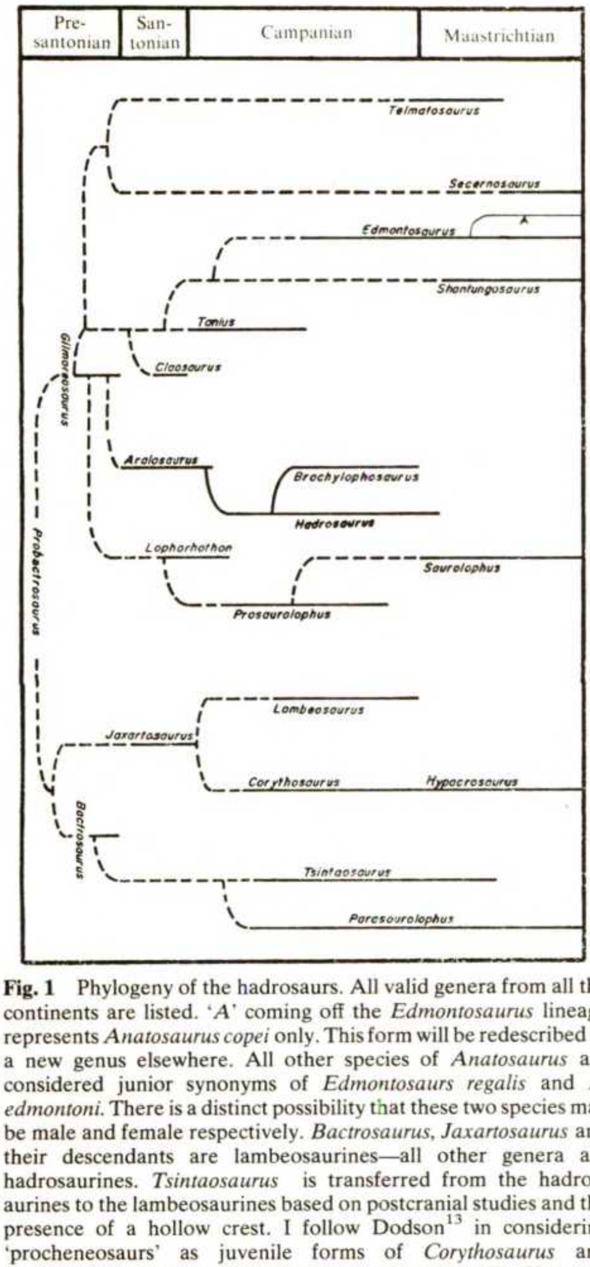

Fig. 1 Phylogeny of the hadrosaurs. All valid genera from all the continents are listed. '*A*' coming off the *Edmontosaurus* lineage represents *Anatosaurus copei* only. This form will be redescribed as a new genus elsewhere. All other species of *Anatosaurus* are considered junior synonyms of *Edmontosaurs regalis* and *E. edmontoni*. There is a distinct possibility that these two species may be male and female respectively. *Bactrosaurus*, *Jaxartosaurus* and their descendants are lambeosaurines—all other genera are hadrosaurines. *Tsintaosaurus* is transferred from the hadrosaurines to the lambeosaurines based on postcranial studies and the presence of a hollow crest. I follow Dodson[13] in considering 'procheneosaurs' as juvenile forms of *Corythosaurus* and *Lambeosaurus*. *Cheneosaurus* is certainly a juvenile *Hypacrosaurus*. *Brachylophosaurus* is transferred from the *Sauroplophus* lineage to the *Hadrosaurus* (*Kritosaurus*) lineage based on postcranial and cranial evidence.

Lambeosaurinae. The Hadrosaurinae are characterised by: relatively low sacral neural spines with a length/width ratio less than 4.5; ventrally grooved sacral centra; long gracile limb elements, non-footed ischium; prepubis with a long thin neck; ilium length/height ratio averaging 4.4; convoluted or slightly expanded pre-maxilla; long straight mandible; solid narial crests (where present). The Lamebosaurinae are characterised by: relatively high sacral neural spines with a length/width ratio greater than 4.5; ventrally ridged sacral centra; shorter and more robust limb elements; footed ischium; prepubis has a short, thick neck; ilium length/height ratio averages 5.4; greatly expanded premaxilla; shorter and anteriorly decurved mandible; hollow narial crests present. Most, if not all, genera in both subfamilies are monospecific. Evidence based on postcranial studies[4] suggests that the Saurolophinae should be included in the Hadrosaurinae.

The three pivotal genera in this report are *Secernosaurus koerneri* (new genus, new species) from Argentina, and *Gilmoreosaurus mongoliensis* (new genus, new combination) and *Bactrosaurus johnsoni*[7] both from Mongolia. All three genera display a primitive grade of organisation reminiscent of their iguanodont ancestry. *Secernosaurus* is the second most primitive hadrosaur known. It is only the second hadrosaur reported from Gondwanaland[8] and the first to be of diagnostic value (the first was by R. Casamiquela). The unique features of its ilium justify a new genus:

Class, Archosauria
Order, Ornithischia
Family, Hadrosauridae
Subfamily, Hadrosaurinae
Secernosaurus (new genus)

Holotype: FMNH P13423, two ilia, prepubis, scapula, fibula, caudals and partial braincase. Collected in 1923 by J. B. Abbott for the Field Museum of Natural History in Chicago.
Horizon: San Jorgé Formation, Rio Chico, Patagonia, Argentina.
Age: Upper Cretaceous.
Etymology: generic name from the Latin *secerno* which means to sever or divide, referring to its non-Laurasian origin.
Diagnosis: postacetabular process of ilium greatly deflected dorsomedially and elongate, unlike any hadrosaur or iguanodont. Preacetabular process of ilium deflected ventrally at an angle greater than in *Hadrosaurus* (Fig. 2). (I follow Baird and Horner[9] in recognising *Hadrosaurus* as the senior synonym of *Kritosaurus*.) Antitrochanter relatively smaller than in any hadrosaur of the same size.

Secernosaurus koerneri (new species)

Diagnosis: same as for genus.
Etymology: specific name after Dr Harold E. Koerner, professor emeritus, University of Colorado.

Gilmoreosaurus is the first representative of the Hadrosaurinae in Asia. It was originally described as a new species of the genus *Mandschurosaurus*[7] but this genus was proved to be a *nomen dubium*[4]. The species, however, contains many features that are partly iguanodont and partly hadrosaurine, hence it is appropriate to recognise this form as a valid genus:

Gilmoreosaurus (*Mandschurosaurus*) *mongoliensis*
(new genus, new combination)

Holotype: redesignated American Museum of Natural History 6551.
Horizon: Iren Debasu Formation, Cenomanian?
Diagnosis: same as original description for species[7].
Etymology: after Charles W. Gilmore, the original author.

Bactrosaurus, the first known lambeosaurine, occurs with *Gilmoreosaurus* in the same formation. The two subfamilies (Lambeosaurinae and Hadrosaurinae) are already separate at this time, which would put the origin of the family some time in the Middle Cretaceous.

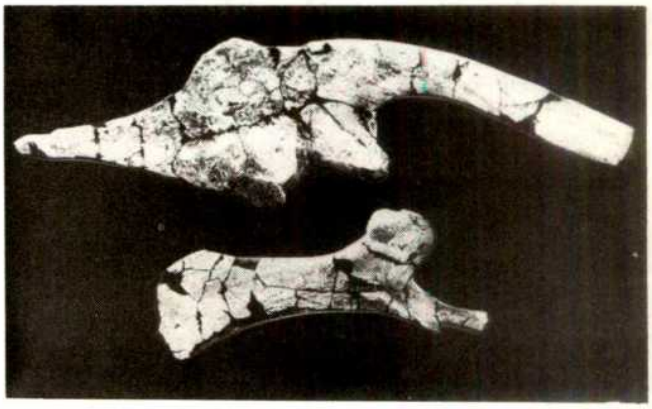

Fig. 2 *Secernosaurus koerneri* (new genus and species). Holotype FMNH P 13423. Right ilium and left prepubis in lateral view. Length of ilium between perpendiculars is 533 mm.

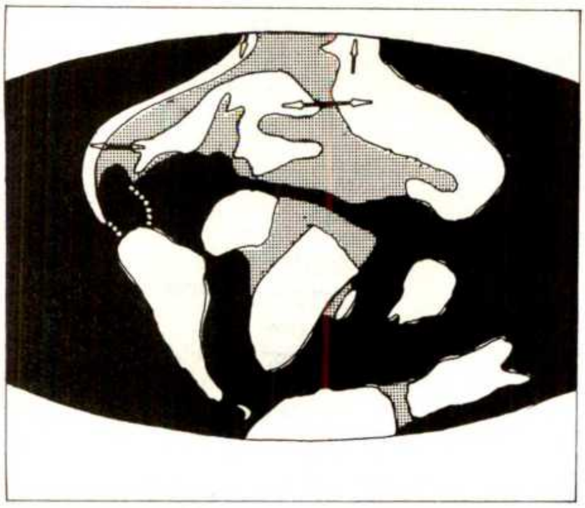

Fig. 3 Palaeogeographic reconstruction of the continents during the Turonian Transgression. Based on Tedford[2] and Smith and Briden[11].

Hadrosaurs[7,10] are considered to have originated in Asia where *Probactrosaurus*, an iguanodont and probable ancestor, has been found. The predominance of primitive hadrosaurs and advanced iguanodonts in Laurasia does not necessarily imply that the family originated there. The fossil record only indicates that by the Mid Cretaceous, hadrosaurs were present in both Laurasia and Gondwanaland, and that they had differentiated into two subfamilies. Dispersal between South America and Laurasia could have been by way of Africa or North America (Fig. 3). Most workers[2,11] believe that Africa was isolated from South America sufficiently early so as not to have been involved in the Upper Cretaceous dispersal of marsupials, so that dispersal must have occurred by way of North America. The two possible links with South America were through Panama or the Caribbean arc. Both hadrosaurs and ceratopsians[12] are found in South America and so the route used must have been a major land connection at some time because both groups consist of large terrestrial vertebrates not subject to waif dispersal or rafting. Dispersal is not considered to have occurred after the Late Cretaceous transgression, because Santonian hadrosaurs were already advanced (derived) beyond the *Secernosaurus* grade of evolution.

It is possible that the presence of hadrosaurs in Laurasia and Gondwanaland represents vicariance rather than dispersal; if so, hadrosaurs would be expected to occur on most continents. Their absence in India and Australia, where Upper Cretaceous deposits with vertebrates are known, indicates otherwise. This, however, is negative evidence and disprovable. Until hadrosaurs are found in India and Australia, the dispersal model is to be favoured.

Kanamycin-resistant *Scenedesmus obliquus* showing simultaneous resistance to other antibiotics and polychlorinated biphenyls

WE have been studying the effects of polychlorinated biphenyls (PCBs) and DDT on several planktonic algae, and report here that we have isolated a kanamycin-resistant strain of *Scenedesmus obliquus* which shows simultaneous resistance to other antibiotics, PCBs and Cetavlon (ICI), a quaternary ammonium compound with algicidal properties[2]. This novel observation suggests a possible genetic control of sensitivity to PCBs in *Scenedesmus*.

S. obliquus (UTEX 2015) was one of the test organisms and was obtained as an axenic culture. This strain was grown mixotropically in liquid TAP (Tris–acetate–phosphate)[4] and when phototrophic growth was being tested acetate was omitted from the medium, which was then a minimal TAP (M-TAP). *S. obliquus* was able to grow on M-TAP in light, thus confirming it to be a phototrophic strain. Agar plates were prepared by adding 1.5% of agar (Difco) to the liquid medium. Required concentrations of antibiotics were filter sterilised and added just before the plates were poured. To test for sensitivity or resistance to antibiotics, 0.1 ml of a *S. obliquus* culture containing 1×10^7 cells ml^{-1} was spread on TAP- and M-TAP-containing antibiotic plates. The plates were incubated for a week in a growth cabinet at 22 °C with continuous illumination. Growth was determined visually.

The control plates without antibiotics showed a heavy growth in the form of a continuous green lawn; there was no comparable growth on antibiotic-containing plates. Thus, we concluded that *S. obliquus* was sensitive to kanamycin (100 μg ml^{-1}), chloramphenicol (50 μg ml^{-1}), streptomycin (300 μg ml^{-1}) and tetracycline (50 μg ml^{-1}). However, when these plates were held at 22 °C for 1 month, we found 7–8 discrete, actively growing colonies on each of the kanamycin-treated plates only. These

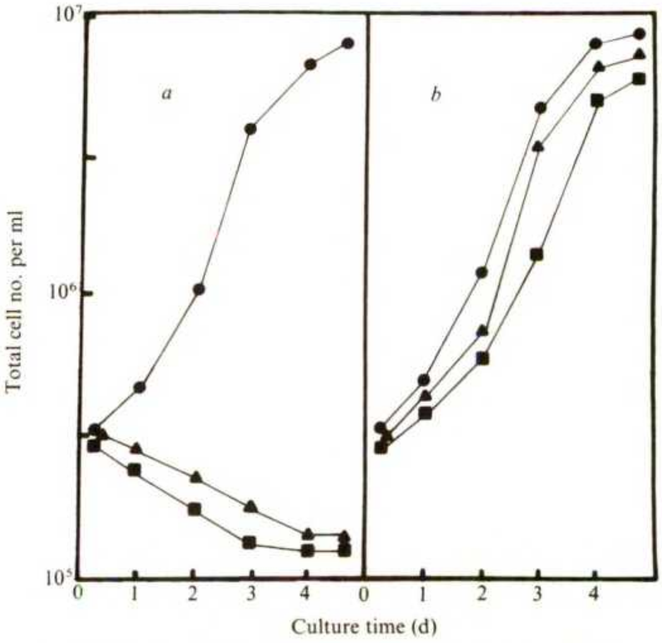

Fig. 1 Effects of PCBs (Aroclor 1242) and Cetavlon on the growth of *S. obliquus* (*a*) and kanamycin-resistant *S. obliquus* (*b*). Cells were grown in liquid TAP and total cell number represents viable cell counts within a 90% confidence level. ●, control; ▲, 5 p.p.m. Aroclor 1242; ■, 5 p.p.m. Cetavlon.

0028–0836/79/0277—0562$01.00

colonies were isolated and named 2015-kr (kanamycin resistant) cells of *S. obliquus*, and cells from each colony were tested separately on TAP plates containing various antibiotics. The progeny of each colony showed similar results and so were treated as a single resistant strain for further experiments. When these presumptive mutants were tested on kanamycin, streptomycin, chloramphenicol and tetracycline plates, they all showed simultaneous resistance on TAP plates. The property of simultaneous resistance had become a permanent feature; this was confirmed by repeated tests on antibiotic-containing plates. Surprisingly, 2015-kr cells failed to grow when plated on TAP media without acetate (M-TAP) supplied with the antibiotics, although the original strain could grow equally well on M-TAP or TAP.

Examination under the optical microscope showed these cells (2015-kr) to be smaller and more round than the parental strain, and lacking coenobia, characteristic of *Scenedesmus*. However, to prove that these were a true derivative of *Scenedesmus* and not a contaminant of another alga, we grew this strain on several different media including some which were unfavourable for active growth of *S. obliquus*. In one such medium, proteose agar, the resistant cells did not show active growth but did produce typical *Scenedesmus* morphology[3]. The identity of these cells was then independently confirmed as *Scenedesmus*.

Previously, *Scenedesmus* (2015) was found to be sensitive to PCB at 0.25 p.p.m. and to an algicide, Cetavlon, at the 1 p.p.m. level. When the kanamycin-resistant variety was tested on these chemicals it was found to be resistant above the 5 p.p.m. level, a concentration lethal for the parent strain (Fig. 1).

The fact that 2015-kr cannot grow on the M-TAP containing antibiotics suggests that the genes affected here are possibly chloroplastic. However, both the parental strain and 2015-kr could grow on M-TAP without antibiotics; this indicates that *S. obliquus* was phototrophic whereas 2015-kr behaved as an obligate heterotroph in the presence of antibiotics. Extensive work on the inheritance of antibiotic resistance involving chloroplastic genes has been carried out in *Chlamydomonas reinhardtii*[1,9–12], where it was shown that many of the mutations conferring antibiotic resistance were present in clusters in chloroplastic DNA. Streptomycin has been used as a selective agent to isolate resistant strains to other antibiotics in *C. reinhardtii* and these mutations were also mapped as chloroplast mutations[1]. However, *C. reinhardtii* possesses a sexual cycle which enables easy differentiation between nuclear and cytoplasmic genes, whereas *Scenedesmus* reproduces asexually and so it is not possible to carry out genetic crosses. Although there is one report of sexuality[8] in *Scenedesmus*, it has not yet been confirmed.

Our previous studies on *Chlorella* and *Spirodella*[5–7] in relation to their sensitivity to PCBs showed that photosynthesis was inhibited by these chemicals. Sensitivity to PCBs could be decreased by addition of a supplementary carbon source to the medium which allowed the cells to by-pass the inhibitory effects of PCBs (in preparation). We believe this to be the first report of an alga, previously sensitive to PCBs and several antibiotics known to affect chloroplast ribosome synthesis, which has acquired simultaneous resistance to all these chemicals. This suggests that, for *Scenedesmus* at least, responses to environmental pollutants such as PCBs can be controlled by specific genes similar to those conferring antibiotic sensitivity. These genes seem to be located in the chloroplast, but the possibility of their being nuclear genes concerned with the function of cytoplasmic organelles is not ruled out.

More recently, we have been able to repeat the isolation of kanamycin-resistant *Scenedesmus* cells; *S. obliquus* will apparently produce approximately one resistant cell per 5×10^5 cells, but this mutation only occurs on kanamycin plates when grown over a period of 1 month. These new isolates are under further investigation.

This work was supported by a grant from NZ Water and Soil Conservation. I thank Dr G. MacRaild for the identification of *Scenedesmus*, Dr J. R. L. Walker for advice on the manuscript and Mrs. G. Evans for technical assistance. *S. obliquus* was obtained from the University of Texas.

Ciliate protozoans as links in freshwater planktonic food chains

THE potential importance of bacteria in freshwater planktonic food webs is recognised[1], but the mechanisms of their incorporation are not fully known. Most planktonic bacteria are not attached to particles and are less than $1\ \mu m$ (refs 2–4) in size—a range inefficiently filtered by crustacean zooplankton[5]. *Daphnia* and *Diaptomus* feed at lower rates on free living bacteria than on algae[6,7]. Bacterial food sources have been used with varying degrees of success to culture zooplankton[8–11]. These variations may be due to the unnatural range of concentrations used and the uncontrolled effects of different culture media, laboratory strains and the degree of accessibility to the zooplankton (because of cell clumping and sedimentation). Ciliate protozoan microzooplankton may be important intermediaries which transform ultrafine organic matter, including bacteria, into a particle size range readily available to crustacean zooplankton. Here we present evidence that ciliates are cropped by crustacean zooplankton in the natural environment. We have also measured feeding, filtering, and assimilation rates of *Daphnia magna* on both a large and small ciliate in the laboratory and have observed feeding behaviour directly. Dissolved organic carbon, bacteria, ciliate protozoans and crustacean zooplankton may represent a significant pathway of carbon flow in the freshwater plankton.

Ciliate protozoa ingest bacteria in nature[12] and grow on them as a sole food source in the laboratory[13]. Furthermore, field studies indicate that planktonic ciliates are actively preyed on in nature. Manipulations of crustacean zooplankton densities in enclosures of lake water[14] reveal that ciliates, as well as algae, are reduced in abundance when crustacean zooplankton densities increase (Table 1). In these field studies, remains of ciliates were found in the feeding appendages and gut contents of the copepod *Cyclops scutifer*. Other microzooplankton, the rotifers, were unaffected by manipulations of crustacea, indicating that they are not major links in this system. Similar reductions in protozoan numbers in the presence of marine copepods occurred in laboratory studies[15].

Feeding studies of *Daphnia magna* were made using the large ciliate *Paramecium caudatum* ($70\times200\ \mu m$; volume $6.15\times10^6\ \mu m^3$) and the small ciliate *Cyclidium glaucoma* ($20\times30\ \mu m$; volume $6.54\times10^4\ \mu m^3$). Protozoans were raised on suspensions of *Enterobacter aerogenese*. Bacteria were grown for 24 h at 38 °C in defined medium, and resuspended in Cerophyll to a final concentration of 1×10^6 cells ml^{-1}. Protozoans were saturation labelled by incubating in this suspension for 7 d at 24 °C. They were separated from the bacteria by geotaxis[16] and

Table 1 Effect of manipulations of crustacean zooplankton on algae and microzooplankton

	Levels of crustacean abundance*				
	Absent	Natural	Enriched	χ^2	P
Ciliates	35.0	25.0	12.0	22.167	<0.001
Total algae	35.0	24.0	13.0	20.167	<0.001
Rotifers†	24.5	33.5	18.0	1.792	NS

**Daphnia galeata mendotae*, *Diaptomus minutus*, *Cyclops scutifer*, and *Epishura lacustris* were removed by filtration or enriched 8-fold in 0.5 m^3 enclosures of lake water on 12 occasions throughout the year[14]. Whole water was collected from the enclosures after 4 d, fixed with Lugol's iodide preservative and counted with an inverted microscope. Because of seasonal variations in abundance, data are reported as sums of ranks. Actual ciliate counts from natural epilimnetic lake water ranged from 0.3 ml^{-1} to 9.0 ml^{-1}. Ranks were summed for each level over the 12 dates and used to compute a Friedman χ^2 with a critical value of 6.167 ($P<0.05$). NS, not significant.

†*Keratella*, *Kellicottia* and *Conochilus*.

resuspended in filtered (0.45 μm Millipore), autoclaved aquarium water in which the experimental *D. magna* were raised. Protozoans were sized, counted in a Sedgewick–Rafter cell and diluted to a final concentration of 135 individuals ml^{-1} (0.985 μg dry weight ml^{-1}) for *P. caudatum* and 2.55×10^3 individuals ml^{-1} (0.823 μg dry weight ml^{-1}) for *C. glaucoma*. Both concentrations are above the incipient limiting concentration for *D. magna* and thus feeding rates were maximised.

Observations of *D. magna* feeding on individual *P. caudatum* were made using an inverted microscope (Zeiss) with 10× eyepieces and a 63-mm Luminar objective permitting a working distance of 6.0 cm and a 2.0-mm depth of field. Live *D. magna* were suspended in a large volume feeding chamber (5×5×5 cm) by attaching the head shield to a fine glass rod tipped with silicone grease. This is an improvement over previous methods of observing compressed *Daphnia*, as it allows free circulation of feeding currents and unobstructed movements of the abdomen, swimming appendages and carapace.

The bacterium *Enterobacter aerogenes* assimilated the ^{14}C-labelled glucose and served as a food source for the protozoans which incorporated the label. *D. magna*, in turn, assimilated this carbon from the protozoans it ingested. Filtering rates of *D. magna* fed on either protozoan showed a positive linear relationship to body size (Fig. 1). *D. magna* ingestion, filtering, and assimilation rates were higher when fed the smaller protozoan, *C. glaucoma*, which is in the size range of many algae, than when fed the large *P. caudatum* (Table 2). Ingestion and filtering rates on both protozoa were lower than rates measured in similar conditions on algae, although the assimilation efficiencies were comparable[17].

Table 2 Mean ingestion rates, assimilation rates, and assimilation efficiencies for *Daphnia magna* fed on *Paramecium caudatum* and *Cyclidium glaucoma*

Food organism	Ingestion rate* $\bar{x}\pm$s.e.m.	N	Assimilation rate* $\bar{x}\pm$s.e.m.	N	Assimilation efficiency
P. caudatum	0.1785±0.0335	5	0.1166±0.0103	4	65%
C. glaucoma	0.4793±0.0110	5	0.3161±0.0303	4	66%

Ingestion and assimilation rates were measured by adding 25–35 *D. magna* to replicate 300 ml BOD bottles containing protozoan suspensions and measuring radioactive uptake in 15 min and incorporation during 1 h (ref. 17). *D. magna* of comparable body sizes were used to measure ingestion rates and assimilation rates for the two species of protozoa. Assimilation efficiencies are calculated as the per cent of the material ingested that is assimilated.

*Ingestion rates ($t=2.608$, $P<0.025$) and assimilation rates ($t=6.232$, $P<0.001$) were significantly different for the two protozoa.

Rates are expressed as μg dry weight of food per animal per hour.

Abbreviations: $\bar{x}$, mean; s.e.m. standard error; N, No. of replicates.

Observations of *Daphnia magna* feeding on *P. caudatum* indicated that only some of the protozoans that entered the filtering current were brought inside the carapace and into the food groove. These were broken up by the movement of the thoracic appendages, labrum, and mandibles and ingested with some loss of material. This slovenly feeding in *Daphnia* is analogous to loss of food material in the mouth parts of other planktonic crustacea[18]. This confirms the interpretation of observations made of animals feeding on large or elaborately shaped algal cells and colonies[19]; food particles, with dimensions larger than the maximum size of rigid spherical particle (38 μm for *D. magna*)[20] that can be ingested whole, can be manipulated and ingested but with reduced efficiency. Measured filtering rates of these particles will be less than the actual rate at which water passes through the filtering apparatus because of rejection of particles that clog the filtration apparatus and loss of material broken up during filtration. The upper and lower limits to the particle size ranges available to *Daphnia* are thus not absolute. Rather, there is a decrease in handling efficiency as particles move away from an optimal size range. Optima for different age classes and species may be the mechanisms by which zooplankton divide up food resources. Behavioural changes may allow individuals to shift optima to accommodate different food particle spectra.

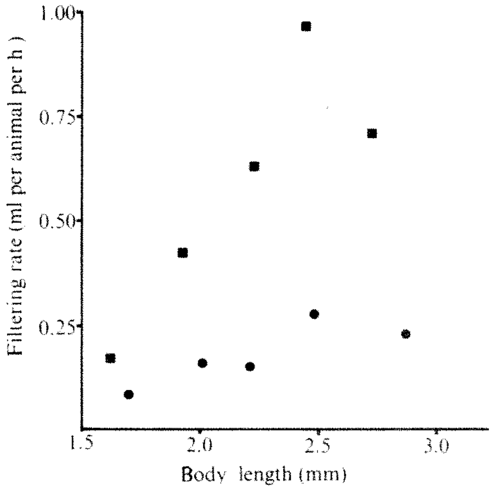

Fig. 1 Filtering rates of *Daphnia magna* on the small ciliate (20×30 μm, *Cyclidium glaucoma* (■), and the large ciliate (70×200 μm), *Paramecium caudatum* (●).

Studies of ciliates feeding on bacteria suggest that a minimum concentration of approximately 10^6 bacteria ml^{-1} is necessary for growth and reproduction of protozoans[21,22]. Nominal concentrations of bacteria in lakes range from 10^5 to 10^6 ml^{-1} (ref. 2). During the declining phase of algal blooms, however, bacterial production is elevated and high concentrations of ciliates (10^2 ml^{-1}) have been observed[23]. Protozoans may also be concentrated in zones near the metalimnetic boundaries, at chemoclines, and above the sediments[24]. If these organisms are cropped by larger zooplankton, as our field and laboratory experiments suggest, then they represent, at least temporally, an important mechanism by which DOM, bacteria, and ultrafine detritus enter planktonic food chains.

Low levels of fixed nitrogen required for isolation of free-living N_2-fixing organisms from rice roots

ISOLATION and counting of N_2-fixing bacteria from the natural environment have until now been conducted on selective N-free media. It is likely that some N_2-fixing bacteria are overlooked by using this procedure. We now report that most of the bacteria present in rice roots are N_2-fixers, but that they require a supply of mineral or organic N for growth. In the presence of organic nitrogen, nitrogenase activity is detected in these organisms. The requirement for organic nitrogen for the detection of nitrogenase is also true for N_2-fixing cultures of free-living rhizobia[1–3].

Rice plants (IR26) were dug out from an unfertilised wetland rice field and the roots were washed to remove soil. The washed roots were cut into segments and shaken vigorously with glass beads to remove rhizoplane bacteria. After several washings the root fragments were macerated to provide a suspension of 'inner rhizoplane' bacteria. The lower portion of the stem was also blended to make a suspension of bacteria living in or on the stem. Suspensions were made in sterile tap water and diluted without exclusion of oxygen. Diluted suspensions were spread on tryptic soy agar (0.1% Difco tryptic soy broth and 1.5% Noble agar), a medium used for counting aerobic heterotrophs[4]. The population of heterotrophic aerobic bacteria per g fresh weight sample was 2.3×10^7 organisms for rhizosphere soil, 1.2×10^7 for stem, 1.5×10^7 for rhizoplane, and 1.1×10^8 for inner rhizoplane.

Colonies from each fraction were selected and tested for nitrogenase activity using the acetylene reduction assay. Acetylene reduction activity (ARA) was measured for a 24-h period after 3 days growth at 35 °C on semi-solid glucose yeast extract medium (in $g\,l^{-1}$: 5.0 glucose, 0.1 Difco yeast extract, 0.5 K_2HPO_4, 0.04 $FeSO_4 \cdot 7H_2O$, 0.2 $MgSO_4 \cdot 7H_2O$, 0.0059 $NaMoO_4 \cdot 2H_2O$, 0.2 $CaCl_2 \cdot 2H_2O$; in $mg\,l^{-1}$: 0.15 H_3BO_3, 0.11 $ZnSO_4 \cdot 7H_2O$, 0.07 $CoSO_4 \cdot 7H_2O$, 0.005 $CuSO_4 \cdot 7H_2O$, 0.004 $MnCl_2 \cdot 4H_2O$, *p*H 7.0, and Difco Noble agar 1.75 $g\,l^{-1}$). The percentage of bacterial isolates proving nitrogenase positive (more than 6 nmol C_2H_4 per tube) was 81% (95/117) for inner rhizoplane bacteria, 76% (19/25) for rhizoplane bacteria, 37.5% (9/24) for bacteria from the stem, and 2.4% (1/41) for rhizosphere soil bacteria.

Because of the high percentage of inner rhizoplane isolates showing nitrogenase activity, the nutritional requirement of bacteria of the most predominant colony type (about 90% of nitrogenase positive isolates) was studied further. None of the isolates could grow on nitrogen-free basal medium (glucose + mineral salts). The majority (31 of 40) grew on basal + ammonium medium (NH_4Cl 61 $mg\,l^{-1}$), but the growth was much poorer than on basal medium supplemented with casamino acids (vitamin-free, Nutritional Biochemicals) or yeast extract (0.1 $g\,l^{-1}$).

For isolates that grew best on basal medium plus casamino acids, nitrogenase activities were measured after 3 days of growth on various semi-solid media (Table 1). Activities were high in the presence of casamino acids but a vitamin mixture only slightly stimulated activity. No activity was detected in N-free medium or ammonium-supplemented medium. Each amino acid was tested individually and all could support growth and nitrogenase actvitity.

Table 1 Acetylene-reducing activity of inner rhizoplane isolates in semi-solid media

Medium	C_2H_4 produced (nmol per tube per day)
Expt 1 (28 isolates tested)	
Basal (glucose + mineral salts)	0
Basal + yeast extract (0.1 $g\,l^{-1}$)	97 ± 11
Basal + NH_4Cl (16 mg N l^{-1})	0
Basal + casamino acid (0.1 $g\,l^{-1}$)	96 ± 18
Basal + glutamic acid (0.1 $g\,l^{-1}$)	39 ± 8
Expt 2 (29 isolates tested)	
Basal + yeast extract	219 ± 17
Basal + casamino acid	144 ± 13
Basal + glutamic acid	120 ± 22
Basal + yeast extract + succinic acid (10 mM)	202 ± 14
Expt 3 (29 isolates tested)	
Basal + casamino acid	222 ± 7
Basal + vitamin mixture*	58 ± 4
Basal + vitamin mixture + casamino acid	251 ± 13

*Vitamin mixture: vitamin B12, 0.015 μM; *p*-aminobenzoic acid, nicotinic acid, biotin, riboflavin, pyrodoxine, folic acid, and Ca-pantothenate, all 0.8 μM.

The extent of inhibition of nitrogenase activity in the presence of oxygen was determined. When initial p_{O_2} was 0.01 atm, nitrogenase activity was maximal while at p_{O_2} 0.2 atm and 0.05 atm, nitrogenase activity was not detected. In anaerobic ($p_{O_2} < 0.001$) culture, slight activity of nitrogenase was detected. Like other aerobic N_2-fixing bacteria, such as *Azospirillum*, these bacteria require microaerophilic conditions for the expression of nitrogenase.

To confirm N_2-fixing activity a gas mixture composed of 20% $^{15}N_2$ (98 atom % excess), 1% O_2, 79% Ar was introduced into 4-day static bacterial cultures on basal medium plus glutamate (0.1 $g\,l^{-1}$) and grown for the following 24 h at 35 °C. The two isolates used for the analysis incorporated 0.18–0.25 atom % excess into cellular nitrogen. *Azospirillum lipoferum* (SpBr17), which was used as a positive check strain, showed a higher rate of incorporation (1.16 atom % excess). Excretion of fixed nitrogen into the medium was negligible in all cases.

Nitrogenase-positive isolates from the inner rhizoplane were all small rods (0.5×2.6 μm), Gram-negative, catalase and oxidase positive, lacked cellular motility, and produced acid from lactose, sucrose, and glucose without gas formation and reduced nitrate. Thus these isolates resemble *Achromobacter*[5,6]. The only known N_2-fixing isolate of this genus was reclassified as *Klebsiella pneumoniae*[7].

A possible explanation for the inability of the isolates to grow on nitrogen-free media is that the nitrogenase activity (as measured by ^{15}N experiments) is too low. A low oxygen concentration produced in the presence of greater cell mass might be more favourable for nitrogenase production, however. The

0028-0836/79/0277—0565$01.00

oxygen factor is another possible explanation of the growth characteristics. Free-living N_2-fixing rhizobia[8] are unable to grow on N-free media because they cannot assimilate fixed nitrogen: this is probably not the case for our root isolates as excretion of fixed nitrogen into the medium was negligible. We have not yet studied the role of amino acids in nitrogenase induction.

The use of nitrogen-containing media for the isolation of nitrogenase-positive bacteria could reveal a much higher incidence of nitrogenase genes in prokaryotes than was previously suspected.

This work is supported by UNDP fund. We thank Dr O. Ito for ^{15}N analysis and Dr J. Döbereiner for the *Azospirillum* strain.

Postnatal cerebellar cells of *staggerer* mutant mice express immature components on their surface

THE histogenesis of the central nervous system is controlled, in part, by a defined sequence of cell-surface interactions[1,2]. Cell-surface carbohydrates are prominent constituents of the external faces of plasma membranes[3–5] and are thought to be important to biological recognition[6,7]. Recently, it has also been shown that some cell-surface carbohydrates change during the first 2 d after birth, an important period in development of the mouse cerebellum[8,9]. Certain neurological mutations have been shown to express defects in positioning of particular cell types at various stages during cerebellar histogenesis[2,11–13]. One of the most interesting of these is the *staggerer* (*sg*) mutant[14]. In this disorder granule cells degenerate after they have migrated into position in the granular layer. Before this expression of the disorder, the sites of synapse formation between the parallel fibre axons of granule cells and the dendrites of Purkinje cell neurones fail to form; in fact, even the tertiary branchlet spines, the potential postsynaptic sites, do not form[15–19]. Even at birth, before obvious expression of the Purkinje cell defect, external granule cells of *sg* exhibit a reduced proliferative rate which results in a reduced number of external granule cells[20].

In this report, antibodies specifically directed against microbial polysaccharides have been applied as carbohydrate probes to developing cerebellar cell populations *in vitro*. Anti-meningococcus type-B polysaccharide antibodies (anti-B) (antigenic determinant neuraminic acid) preferentially react with pre- and neonatal cerebellar cells of C57BL/6J mice, but do not react with 7-d-old (P7) cells. Anti-α-1,6-mannan antibodies, on the other hand, react with both prenatal and postnatal cerebellar cells. Comparable results have been obtained with lectins as surface carbohydrate probes[10]. Agglutination of cerebellar cells with concanavalin A and wheatgerm agglutinin decreased from embryonic day 13 (E13) to postnatal day 7 (P7). Using anti-B and anti-α-1,6-mannan antibodies to determine the distribution of their respective antigens on the surface of +/+ and *sg/sg* cerebellar cells *in vitro*, we found that P7 *sg/sg* cell cultures express immature cell-surface carbohydrates.

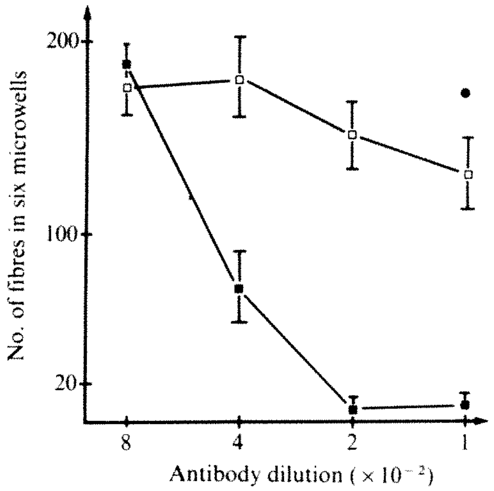

Fig. 1 Inhibition of fibre formation in microwell cultures of 7-d-old *sg/sg* cerebellum in the presence of various dilutions of anti-meningococcus type-B antibodies (anti-sialic acid) (■). The inhibition was overcome when antibodies were incubated overnight with 10 µg of meningococcus type-B polysaccharide before adding the antigen–antibody complex to the culture (□). Normal rabbit serum did not inhibit fibre formation (●). The numbers plotted represent the mean of three experiments of the total number of fibres in six microwells.

The present work is one step in a study to determine whether the defect in some of these neurological mutants might be in cell-surface constituents and whether their alterations might affect the sequence of cell–cell interactions required to generate functional connections in the developing cerebellum.

A microwell tissue culture system, in which cells show certain behaviours reminiscent of *in vivo* cerebellar development[21], was used to determine anti-carbohydrate antibody reactivity. This system allows the assay of differential cell assembly, migration and fibre outgrowth. The large number of very reproducible

Table 1 Fibre outgrowth in microwell cultures of 7-d-old *sg/sg* and +/+ cerebellum in the presence of anti-carbohydrate antibodies

			No. of fibres in 6 microwells			
Expt	Antibody	Dilution	+/+	% Inhibition	*sg/sg*	% Inhibition
1	Rabbit serum	1:50	180		193	
2			178		169	
3			222		176	
1	Anti-B	1:200	162	10	16	92
2			148	17	12	93
3			195	12	38	78
1	Anti-α-1,6-mannan	1:300	14	92	129	33
2			2	99	118	30
3			8	96	108	39

A single-cell suspension (1×10^7 cells ml^{-1}) of 7-d-old +/+ and *sg/sg* cerebellum, respectively, were plated at 5 µl per microwell, and 5 µl of antibody dilution in medium then added. Fibre formation was scored in six microwells after 2 d *in vitro* using a phase contrast light microscope. The variation among cultures was determined as ±20%. The data represent the total number of fibres in six microwells obtained in three different experiments. The number of fibres obtained in cultures containing rabbit serum were used as standard for 100% fibre formation per experiment.

0028–0836/79/0277—0566$01.00

cultures obtained from each cerebellum provides a statistically suitable assay system for study of the functional effect of reagents that bind to specific cell-surface components. The number of fibre cables formed between cell aggregates was determined in the present study as a quantitative assay for antibody reactivity.

sg/sg Mutant mice were obtained on an inbred background (C57BL; $^{+}dse/sg^{++}$) as bred in our own colony. P7 cerebella of *sg/sg* and +/+ (*dse/dse*) were removed and dissociated into single cells as described elsewhere[21]. Single-cell suspensions contained $2–3 \times 10^6$ (*sg/sg*) and $1–2 \times 10^7$ (+/+) cells per cerebellum. Cells were cultured in basal Eagle's medium, supplemented with 10% horse serum (Gibco) at a concentration of 5×10^4 cells per 10 μl per microwell.

Table 2 Results of radioimmunoassay to determine cell-surface carbohydrate patterns in +/+ and *sg/sg* cerebellum

Antibody	Dilution	Radioactivity (c.p.m.) +/+	*sg/sg*
Rabbit serum	1:50	20±5	15±7
Anti-B	1:200	50±30	16,000±1,200
Anti-B + 10 μg meningococcus type-B polysaccharide	1:100	65±15	220±65
Anti-α-1,6-mannan	1:300	12,000±300	2,550±275
Anti-α-1,6-mannan + 40 μg Δ1,6-mannan	1:100	70±25	110±35

P7 +/+ and *sg/sg* cerebellar cells were cultured as described in the legend to Table 1. After 16 h *in vitro*, cultures were washed once in ice-cold phosphate-buffered saline (PBS). 5 μg of ^{125}I-labelled purified goat anti-rabbit IgG antibodies (~8.5×10^6 c.p.m. per 14.5 mg goat IgG per ml) were added and cultures incubated at 4 °C. After 2 h cultures were washed twice in 4 °C PBS and once in 10% trichloroacetic acid. The tissue was then removed from the microwell and assayed for counts. Hapten inhibition was carried out as described in the legend to Fig. 1.

The pattern of cell reorganisation in the microwell cultures into cell reaggregates and connecting fibre bundles was identical in *sg/sg* and +/+ cultures[21]. This pattern of *in vitro* cell reorganisation was not unexpected, as *in vivo* histogenesis of *sg* cerebellum is not markedly perturbed as early as P7. Three assay systems were applied to characterise alterations of cell-surface determinants on *sg/sg* cerebellar cells in microwell cultures.

First, the results in Table 1 demonstrate fibre formation in +/+ and *sg/sg* cerebellar microwell culture in the presence of anti-α-1,6-mannan and anti-B antibodies. (Previous studies have shown that these antibodies do not kill living cells[8,9].) Fibre formation in P7 +/+ cell cultures was inhibited 95% with a 1:300 dilution of α-1,6-mannan antibodies, whereas the same antibody concentration inhibited only ~33% of fibres in *sg/sg* cultures. On the other hand, anti-B had little effect on P7 +/+ cultures (~15%), but inhibited fibre formation in *sg/sg* cultures up to 93%. The antibody reaction was polysaccharide specific, as 10 μg ml^{-1} purified type-B polysaccharide inhibited the reaction (Fig. 1), whereas polysaccharides of other specificities (dextran, pneumococcus type C carbohydrate, α-1,6-mannan) had no effect (not shown). Anti-α-1,6-mannan antibody reactivity, on the other hand, was abolished after preincubation of antibodies with yeast *Saccharomyces cerevisiae* mutant X2180-1A-5.

As discussed above, anti-B antibodies block fibre outgrowth in prenatal and neonatal but not P7 cell populations cultured in microwells[8,9]. The inhibition by anti-B antibodies of fibre outgrowth in *sg/sg* cell cultures suggests, therefore, that 7-d-old *sg/sg* cerebellar cells express immature cell-surface carbohydrates. Although cultures are unsuccessful with cerebellum from animals older than P7, preliminary immunohistological data show corresponding cell-surface alterations in cryostat sections of *sg/sg* cerebellum as late as P18 (ref. 22).

In addition to the expression of embryonic cell-surface determinants, alteration of surface characteristics are indicated. As shown earlier[8], anti-α-1,6-mannan antibodies did not discriminate between cells of different age in microcultures of +/+ but inhibited only ~30% of fibre formation in *sg/sg* cultures. The cell-surface determinants expressed on *sg/sg* cerebellar cells *in vitro* and *in vivo* resemble, therefore, not only immature surface antigens (as recognised by anti-B antibodies) but also constituents which seem to be structurally different from those expressed on +/+, as indicated by the loss of anti-α-1,6-mannan-specific antibody-binding sites.

Alterations of cell-surface carbohydrate pattern were detected also by a radioimmune assay using purified ^{125}I-labelled goat anti-rabbit IgG antibodies to detect the anti-carbohydrate antibodies bound to the surface of either +/+ or *sg/sg* cerebellar cells *in vitro*. The results shown in Table 2 confirmed those obtained from fibre outgrowth inhibition studies, in that alteration of cell-surface determinants on *sg/sg* cerebellar cells are in part due to alterations in cell surface carbohydrate pattern accessible to antibody recognition.

Further evidence for the expression of embryonic cell-surface characteristics on postnatal *sg/sg* cells has been obtained by studies of the effect of epidermal growth factor (EGF) on P7 *sg/sg* and +/+ cells cultured in microwells. As discussed elsewhere[23], EGF stimulates E16–P1 astro- and oligodendroglial cells to migrate out of reaggregates and to proliferate, but is without effect on cells older than P1. P7 *sg/sg* cells, however, respond to EGF at doses comparable to those required for E16–P1 +/+ cell response (1.5 μg ml^{-1}) by an increased migration and proliferation of glial cells.

Further studies will be required to elucidate the significance of the expression of immature and/or altered cell-surface molecules to the *sg/sg* mutation, and, in particular, to determine the role of cell-surface carbohydrate in the abnormal cerebellar development of *sg/sg*.

I thank Dr R. L. Sidman for his interest, criticism and support of these studies, Drs Hatten, Noebels and Greene for critical reading of the manuscript, and David Smith for assistance. Supported by NIH grant no. R01 NS11237 to Dr R. L. Sidman.

Destruction of inferior olive induces rapid depression in synaptic action of cerebellar Purkinje cells

THE climbing fibre afferents (CFAs) are a structure unique to the cerebellar cortex; they originate, presumably solely, from the inferior olive (IO) and make an extensive, excitatory synaptic contact with dendrites of cerebellar Purkinje cells (P cells)[1]. The importance of the CFAs in cerebellar functions has been emphasised in connection with the learning process which may occur in the cerebellar cortex[2,3], and also in connection with the development and maintenance of normal dendritic structures of P cells[4–7]. An interesting recent finding is that after destruction of the IO electrical stimulation of the cerebellar cortex fails to elicit the normal inhibitory synaptic action of P cells on their target neurones in vestibular nuclei[8,9]. This not only urges reinterpretation of the symptoms arising from destruction of the IO[10,11], but also raises a basic general problem of remote interaction in neuronal networks. Here, we report that the depression of the P-cell action develops unexpectedly fast following destruction of the IO, and also present evidence indicating that this remote effect is mediated largely by a non-impulse transmission process, presumably an axonal flow, in CFAs and P-cell axons.

The vestibulospinal reflex system was chosen as the experimental material. The lateral vestibulospinal tract cells (LVST cells), located in the nucleus of Deiters, receive monosynaptic excitation from primary vesibular afferents[12] and monosynaptic inhibition from P cells in the lateral zone of the vermis of the cerebellar anterior lobe[1] (Fig. 1*a*). These P cells in turn receive CFAs from the caudal portion of the dorsal accessory olive (CDAO)[13]. Sixteen adult albino rabbits were anaesthetised by α-chloralose plus urethane (60 and 400 mg per kg, respectively), immobilised by gallamine triethiodide, and artificially respired. The dorsal surface of the lower medulla was exposed by opening the atlanto-occipital membrane. A part of the IO was destroyed electrolytically by passage of 0.5 or 1.0 mA d.c. currents for 1 min through a metal electrode (Fig. 1*a*). Location of the metal electrode in the IO was monitored by observing effects of stimulation through it in evoking field potentials in the nucleus of Deiters or in the vermal cortex of the cerebellum, and was later confirmed histologically.

Synchronised reflex discharges of LVST cells evoked by stimulation of the right labyrinth were recorded from the ventrolateral funiculus on the right side at the first cervical segment of the spinal cord[14]. These discharges were effectively inhibited by conditioning stimulation with the cerebellar electrodes placed at a deep lamella of lobule IV or V (Fig. 1*a*), as plotted in Fig. 1*b* as a function of the conditioning–testing time intervals. As demonstrated previously[14], this inhibition represents the synaptic action of P cells on LVST cells. After destruction of the CDAO, the intensity of the P-cell inhibition of LVST cells gradually became much smaller (Fig. 1*b*). The time course of development of the depression is plotted in Fig. 1*c* for four experiments. In two control experiments, where lesions were placed in the rostral portion of the IO, leaving the CDAO intact, there was no depression in P-cell action such as seen in Fig. 1*c*(not shown).

In two experiments, IO destruction was replaced by local application of tetrodotoxin (TTX), which blocks impulse conduction but not axonal flows[15]. While 1 µl of saline solution containing 1.4 µM TTX was injected into the vicinity of the IO every hour or so, complete blockade of impulse activities in the IO was ensured by observing antidromic invasion of IO cells and/or trans-synaptic activation of P cells by stimulation of the IO. In both experiments, as demonstrated in Fig. 1*d*, TTX induced a rapid decline in the cerebellar inhibition but did not, however, reduce it to the extent seen after electrolytic IO destruction; instead, there was a partial recovery at 5–7 h after onset of TTX injection. This initial decline of the cerebellar inhibition was not reproduced by control injections of TTX-free saline solution, as shown by the broken line in Fig. 1*d*, and therefore apparently represents an effect specific to TTX.

Destruction of the IO also affected activation of P cells by CFA impulses. In Fig. 2*a*, the prominent negativity recorded from the molecular layer of the vermal cortex of lobule V represents trans-synaptic activation of P cells by CFAs stimulated in their intracerebellar course[1]. When the CDAO was destroyed together with the caudal portion of the medial accessory olive which projects to the medial part of the vermis[13], the activation of P cells gradually became much less effective in a

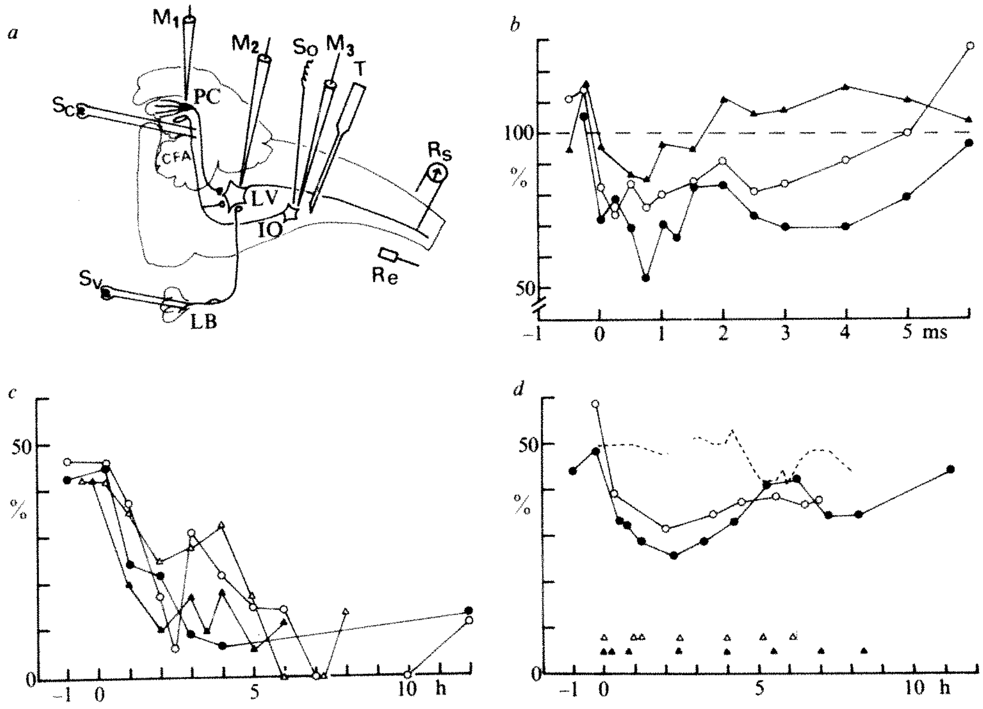

Fig. 1 Effects of destruction of, and local application of TTX to, the IO on P-cell inhibition of LVST cells. *a* illustrates schematically the experimental arrangements on a parasagittal section of the cerebellum and brainstem. PC, P cell; LV, LVST cell; LB, labyrinth; S_v, S_c, S_O and R_s, platinum–irridium needle electrodes, 0.2 mm in diameter, lacquered except for the very tips. One needle of R_s was inserted into the spinal cord, the other was placed on neck muscles. S_O was used for electrolytic destruction of IO. M_1, M_2 and M_3, glass microelectrodes filled with 2 M NaCl solution and having electric resistance of 1.5–2.5 MΩ. M_1 and M_2 were for recording from the cerebellar cortex and the nucleus of Deiters, respectively. M_3 was for examining antidromic activity of IO neurones under the influence of TTX; T, microsyringe containing 1.4 µM TTX-saline solution; R_e, indifferent electrode. *b* Plots amplitudes of LVST-cell discharges evoked by testing stimulation with S_v and recorded with R_s (ordinate), relative to their control size, as a function of the time interval between the conditioning stimulation with S_c and the testing one (abscissa). Three sets of plotted points were obtained before (●), and 4(○) and 12(▲) h after IO destruction in the same experiment. *c* Plots the reduction in LVST-cell discharges at the peak of the inhibition curves as in *b*, relative to their control size, as a function of time. IO destruction ended at 0 h. Results from four animals are superimposed. *d* Is similar to *c*, except for TTX application. For the two cases plotted by ○ and ●, times of TTX injection are indicated by △ and ▲, respectively. The broken line is for the control case where normal saline solution was injected every hour starting at 0 h.

0028–0836/79/0277—0568$01.00

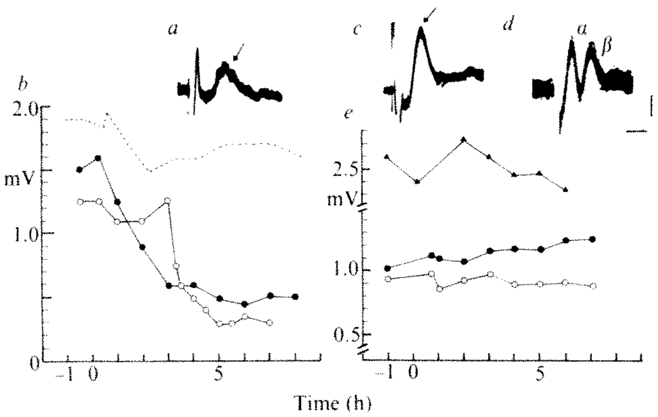

Fig. 2 Effect of IO destruction on CFA activation of P cells and electrical excitability of P-cell axons. *a*, Field potentials evoked by applying pulses of 0.1-ms duration and 0.5-mA intensity through S_c and recorded with M_1 (see Fig. 1*a*). Arrow marks the negativity representing activation of P cells by CFAs. *b*, Peak amplitudes for two animals plotted as a function of time before and after destruction of IO which ended at 0 h. The broken line indicates CFA activation of P cells in the presence of TTX, as shown in Fig. 1*d* (●, ▲). *c*, Field potentials evoked in the Purkinje cell layer by stimulation similar to *a* and recorded with M_1 optimally adjusted for recording antidromic activity of P cells (marked by an arrow). *d*, Field potentials evoked in the nucleus of Deiters by stimulation similar to *a* and *c*. α and β denote two spiky peaks. *e*, Plots amplitudes of antidromic activity of P cells (-▲-) and of α(●) and β(○) spikes, obtained from two animals as a function of time as in *b*. Records *a*, *c* and *d* were obtained by superimposing five successive sweeps repeated at a rate of 5 s^{-1}. For the measurement of these potentials for plotting in *b* and *e*, an average of over 20 successive sweeps was routinely done by use of a data processing computer (ATAC 501-10). Time scale indicated in *d* is 2 ms for *a* and 0.4 ms for *c* and *d*. Voltage scale is 1 mV for *a* and 0.4 mV for *c* and *d*.

time course comparable to that for depression of the cerebellar inhibition of LVST-cells, plotted in Fig. 2*b* for two cases. Local application of TTX induced only a small, somewhat transient depression in the activation of P cells, as indicated by a broken line in Fig. 2*b*.

By contrast, the excitability of P-cell axons was not affected by IO destruction. As shown in Fig. 2*c*, cerebellar stimulation by electrode S_c evoked a prominent negativity in the P-cell layer of lobule V which represented antidromic invasion of P cells. Field potentials similarly evoked but recorded from the nucleus of Deiters contained two spiky components of fast negativity (Fig. 2*d*), the earlier α spike representing volleys evoked in cerebellar afferent fibres and the later β spike those in P-cell axons[1]. Except for relatively small changes presumably arising from inadvertent movement of the recording electrode relative to brain tissues, none of these potentials exhibited systematic change following destruction of the IO (Fig. 2*e*).

The present investigation demonstrates that destruction of IO neurones causes a rapid failure in the excitatory transmission from CFAs to P cells and in the inhibitory transmission from the latter to LVST cells. These effects are specific to portions of the IO related to the vermal P cells and LVST cells, thus excluding the possible contribution of a nonspecific effect of damage to the medulla. As blockade of impulse activities of the IO with TTX produced only a relatively small, transient effect (Fig. 1*d*), the major effect of the IO destruction must be mediated by a non-impulse process, presumably an axonal flow in the CFAs. As impulse conduction in P-cell axons was not affected by IO destruction, it seems also that the postulated disturbance of axonal flow in CFAs affects the axonal flow in P-cell axons across CFA–P-cell synapses, eventually resulting in reduction of either release of the neurotransmitter, presumably GABA[16], from P-cell axon terminals, or postsynaptic reactivity to the neurotransmitter. It may be that P-cell synapses on LVST cells are affected through collateral of CFAs directly innervating LVST cells in the manner of the heterosynaptic interaction (see Fig. 1*a*).

Fast components of axonal flow have a velocity as high as 400 mm d^{-1} (ref. 17), and may travel from the IO to LVST cells through P cells in about an hour. This is fast enough to account for the rapid transfer of the effect of IO destruction to LVST cells, except for the short-term effect revealed within the initial hour (Fig. 1*c*). The short-term effect could be due to removal of impulses from CFAs and/or tissues surrounding the IO, as obtained by TTX blockade; P-cell inhibition of LVST cells might be influenced rapidly through a process such as impulse–axonal-flow interaction[18] in CFAs and/or P-cell axons, or through alteration of background activities of LVST cells, such as removal of the inhibition arising from the medullary reticular formation[19].

We thank Dr M. Yamamoto and Y. Kawaguchi for assistance in some experiments. The work is supported by grant 144025 from the Japanese Ministry of Education, Science and Culture.

Transducer noise in a photoreceptor

IN our attempts to unravel the workings of visual systems, we seek neural responses and interactions which can account for visual behaviour. A popular measure of visual performance is the threshold intensity at which a stimulus is detected with a given probability. To account for these detection tasks, one must not only measure neural signals at threshold[1,2], but also find the limiting sources of variance (that is, the noise) both within[3] and outside[4,5] the nervous system[6]. The manner in which the random nature of photon absorptions can limit the performance of visual systems is well understood[4,5,7,8]. When bleaching effects are negligible, photon absorptions follow the Poisson distribution. Consequently photon counts derived from the same mean signal have a variance equal to their mean. These fluctuations in counts are an inherent property of photon signals and are referred to as photon shot noise. Processes within the visual system generate intrinsic noise[7], but to assess its effect on thresholds one must first account for photon shot noise. This is generally difficult because photon catch cannot be measured directly, and must be estimated from optical parameters which are subject to significant error[7]. We have estimated the levels of photon shot noise and intrinsic transducer noise[9] in locust photoreceptors at low light intensities. We have chosen to search for sources of intrinsic noise in the visual system of the locust because it has recently been shown that, at low intensities, each effective photon produces a single, large quantum bump[10] (Fig. 1). Thus, we measure precisely the number of photons contributing to photoreceptor signals and derive, from the total response variance, that additional variance due to intrinsic noise. We report here that the transducer noise mimics the properties of photon

shot noise, is of similar magnitude, and, in most conditions, must have an equally significant role in determining thresholds.

To examine photoreceptor noise we use techniques perfected in previous experiments[9–12] and estimate receptor performance from intracellular responses to brief monochromatic light flashes (4 ms at 443 nm). Each stimulus falls within the linear integration time of the photoreceptor (which is >10 ms in a dark-adapted locust) so that response amplitude depends on the total number of effective photons delivered. Thus, the photoreceptor is used as a photon counter and problems associated with the statistical analysis of rate-dependent processes are avoided.

For each photoreceptor analysed we first count the number of bumps produced during prolonged periods of dim illumination.

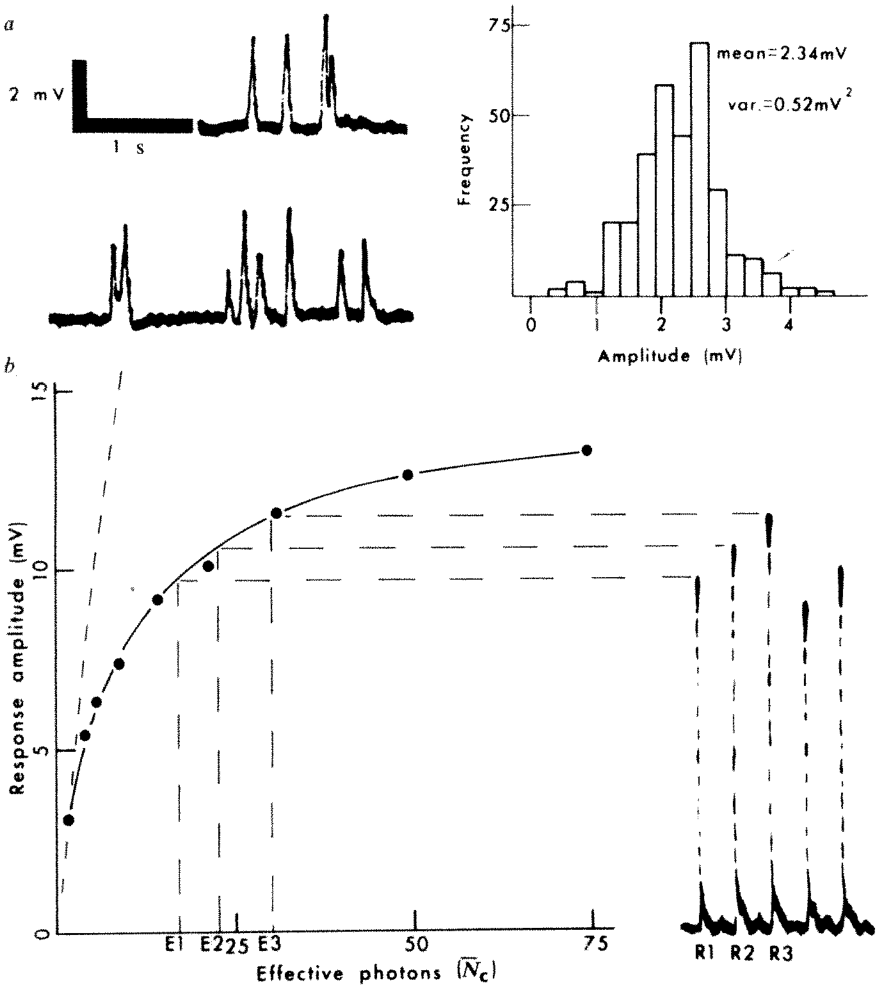

Fig. 1 Measurement of transducer noise in locust photoreceptors. *a* Shows quantum bumps recorded during dim illumination and their amplitude distribution. Their frequency is used to calibrate the effective quantal content of the flashes used to estimate response variance. *b* Demonstrates how an equivalent number of captured photons (E1, E2, E3, and so on) is attributed to responses (R1, R2, R3, and so on) induced by brief, higher-intensity flashes by referring all amplitudes to the intensity/response function. The intensity/response function predicted by the simple self-shunting model (- - -) is much steeper than the empirical (•—•).

This enables us to calculate the mean number of effective photons, $\bar{N}_c$, contained in higher-intensity flashes. Next, we derive the intensity/response function relating mean response amplitude, $\bar{V}$, to $\bar{N}_c$ (Fig. 1). Finally, we measure the amplitudes of response to 100–200 repeated flashes of known mean effective quantal content. Photon and intrinsic noise sources cause these responses to fluctuate in amplitude (Fig. 1) and response variance is measured in units of equivalent effective photons (EEPs) squared by converting every voltage amplitude to an equivalent mean photon count[9,12] using the intensity/response function (Fig. 1). The response variance due to photon shot noise equals $\bar{N}_c$ (from Poisson statistics). The additional response variance due to intrinsic noise is derived by subtracting the photon shot noise from the total response variance. Thus, the degrading effects of intrinsic noise are measured in terms of incident intensity.

Our results (Table 1) show that over a range of 1.7 log units intensity, the random absorption of photons only accounts for 33–67% of total response variance. The remaining fluctuations must be generated within the photoreceptor itself. At low intensities this intrinsic noise is multiplicative, producing variance proportional to mean photon catch, $\bar{N}_c$, in the range $\bar{N}_c = 6$–30. At higher intensities our preliminary observations suggest that intrinsic noise increases in magnitude relative to photon shot noise (Table 1).

We are confident that this intrinsic noise is not an artefact generated by errors in experiment or calibration. Full details of the calibration of the Uniblitz high speed shutter, the constant current tungsten light source, and the interference and attenuating filters are given elsewhere[10]. Calibrations gave consistent results which accurately predicted both relative quantum bump frequencies at different steady intensities and the fraction of successful responses produced by different threshold flash intensities. The accuracy of our method depends on the determination of relative, rather than absolute, stimulus energies, because each cell's quantum catch is measured from bump counts. Rigorous controls ensured that we rejected data from cells whose sensitivity changed during an experiment. A determination of quantum capture efficiency and the intensity/response function preceded and followed every estimation of response noise, which was measured several times at each intensity. The inter-stimulus interval was adjusted to prevent light adaptation. During a single experiment, the resting potential drifted by <0.5 mV (~1%).

We can dismiss several sources of intrinsic noise in the dark-adapted locust photoreceptor. In total darkness, 'spontaneous' photon signals occur at a rate of less than 1 every 360 s (ref. 10) (this is 1 every 160 s for dogfish rods[13]) and will contribute negligible variance to responses to brief flashes. Membrane voltage noise in the dark (400 μV peak-to-peak) is also negligible relative to bump amplitude and this contrasts strongly with the barrage of dark noise in rods and cones[14]. Consequently, in locust photoreceptors, the intrinsic noise described above must be associated with the light response, and so is termed transducer noise[9]. One of us (P.G.L.) has recently eliminated three potential sources of this transducer noise: there is no variance associated with the number of bumps produced by an effective photon[10]; bump size seems to be independent of photon wavelength[11], even in cells containing two or more photopigments, implying that each photopigment produces equal-sized bumps; there is no variance associated with site of photon capture (geometric noise).

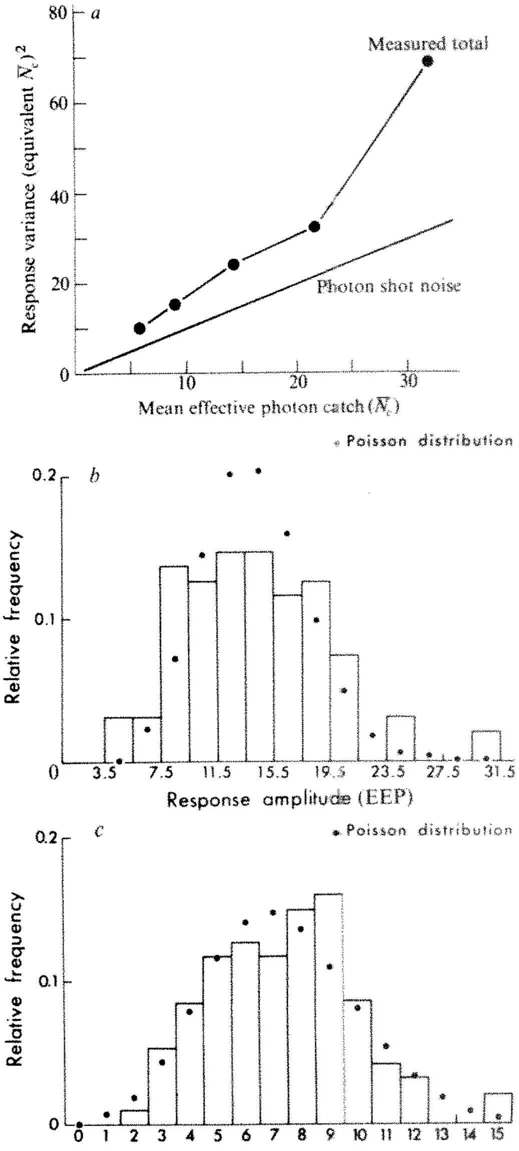

Fig. 2 *a*, Total response variance measured in squared equivalent effective photons (EEPs) plotted against mean effective photon catch per flash. For small responses the total variance is proportional to mean intensity and in this sense mimics photon shot noise. *b*, The frequency distribution of response amplitudes to one series of constant-intensity flashes. Response amplitudes are expressed in EEPs using the methods described in the text. The distribution of amplitudes is broader than that predicted by Poisson statistics from the mean effective photon catch estimated from bump counts (●). This extra scatter is due to transducer noise. *c*, An amplitude frequency distribution plotted from the same data as used in *b*, but here the shot noise analysis described in previous studies[9,12] has been used to assign to each response an effective quantal content. This method assumes that all variance is generated by photon shot noise and calculates the mean quantal content of stimuli from the signal-to-noise ratio of response amplitudes[9] (expressed in equivalent intensity). Again, response noise mimics photon shot noise because the distribution of apparent photon catches is Poissonian. However, intrinsic noise has decreased the signal-to-noise ratio and lowered the apparent photon catch. All data are taken from cell 1, Table 1.

Two known manifestations of transducer noise are the fluctuations in amplitude (Fig. 1) and latency of single photon responses[10]. With respect to amplitude fluctuations, the simplest assumption is that apart from overall response compression, bumps add independently to each other. On this basis one would expect the slope, S, of variance against mean (in terms of EEPs) to be: $S = 1 + (\text{variance(bump amplitude)}/(\text{mean(bump amplitude)})^2)$ (see ref. 15), which is always less than observed; for example, the predicted slope for cell 1, Table 1 is 1.1 rather than the observed value of 1.5–2.0. The disparity presumably indicates that such a simple assumption is not justified. This is suggested by the observation that locust photoreceptors do not possess 'simple' self-shunting membranes (for review see ref. 16) for which the above equation for slope, S, was derived[15]. In this case, total conductance change is proportional to photon catch and a hyperbolic intensity/response function is predicted which greatly overshoots the empirical one (Fig. 1). Thus, a better understanding of the mechanisms which produce this severe response compression seems necessary to assess the effects of bump amplitude variability. Initial modelling of the effects of variable bump latency using Monte Carlo methods suggests that it causes very little response compression and contributes about 10% to observed transducer noise. Clearly, we require a better knowledge of transduction if we are to determine the extent to which the unequal responses to single photon absorptions seen from bumps, contributes to transducer noise.

Can transducer noise influence neural and behavioural thresholds? At intensities so low that bumps do not fuse, single photon hits could be registered in a manner which avoids transducer noise. For example, given the high voltage gain found at the first synapse in the compound eye (reviewed in ref. 17), the second-order cells might produce brief saturating responses for each photoreceptor bump received. However, at higher intensities, bumps fuse and a receptor can no longer act as a perfect photon counter in this manner. Transducer noise blurs the discrete jumps in amplitude resulting from additional photon absorptions, and contributes noise indistinguishable in the intensity domain from photon shot noise (Fig. 2*b*, *c*). Arguments which suggest that the proportionality of increment thresholds to (intensity)$^{1/2}$ indicate a photon-counting system unaffected by intrinsic noise[8], are here demonstrated to be false, because we describe a source of intrinsic noise (transducer noise) which is multiplicative. Thus, although photoreceptor noise has a large intrinsic component, it mimics the statistical properties expected if photon shot noise alone was present[6]. Our measurements suggest that in most conditions transducer noise must be as significant as photon shot noise in determining visual thresholds. Consequently, transducer noise must be considered with other sources of intrinsic noise when accounting for visual performance, for the design of photoreceptors, and for higher-order strategies for optimum sampling of the visual signal[18].

During the revision of this letter, a report was published which suggested that multiplicative noise might degrade human visual performance without distorting the underlying Poisson statistics of photon capture. This would account for the number of quanta apparently detected falling far short of estimated capture by the photopigment[19]. Our conclusions about the effects of transducer noise are clearly similar and establish a precedent for the existence of multiplicative noise within a visual system.

Association of cellular membrane of *E. coli* minicells with the origins/terminus region of replication of plasmid ColEl DNA

COLICINOGENIC plasmid El (ColEl) can be isolated from *Escherichia coli* as a supercoiled DNA molecule of 2.14 μm long or as a supercoiled DNA–protein complex[1]. Certain protein denaturing agents will convert this complex to an open circular (relaxed) DNA form with one single-strand break in the heavy (polyUG binding) strand of the duplex ColEl DNA (refs 2, 3). The induced single-strand break in ColEl DNA is located approximately 19% of the length of ColEl DNA from the single *Eco*RI restriction endonuclease site in the plasmid[4]. Analysis of ColEl replicating intermediates has shown that replication proceeds unidirectionally from an origin located near the position of the relaxation complex nick, approximately 19% from the single *Eco*RI restriction site[5–7]. The site of the relaxation-complex nick has been located approximately 300 nucleotides away from the origin of ColEl DNA replication[9]. The nucleotide sequence of the origin region of ColEl DNA[8,9] and of a small ColEl-type plasmid[10] have been determined. A model for the possible role of the relaxation complex in ColEl DNA replication and/or conjugal transfer has been presented[11]. A major feature of this model is that the relaxation complex proteins may help promote association of plasmid DNA with a replicator and/or conjugal transfer site on the bacterial membrane. We describe here an electron microscopic analysis of *Eco*RI-cleaved ColEl and mini-ColEl DNA that were purified as stable DNA–membrane complexes from *E. coli* minicells. Evidence is presented that membrane-like structures attach to ColEl DNA and mini-ColEl DNA in a region that includes both the site of the origin/terminus of DNA replication and the site of single-strand cleavage by the relaxation complex.

Minicells that contain plasmid ColEl DNA or a hybrid mini-ColEl plasmid containing a kanamycin (Km) resistance fragment (pML21)[13] were purified from *E. coli* P678-54, Thy$^-$. The plasmid DNA in the purified minicells was labelled with ^{3}H-thymidine, the minicells were lysed, and the lysate centrifuged on caesium chloride–sucrose gradients[12]. Figure 1*a* shows that in the conditions of centrifugation the ^{3}H-ColEl DNA from minicells separates into two major peaks, one which rapidly sediments to an isopycnic density of about 1.35 g ml^{-1} (pool *A*), the other remaining near the top of the gradient. A visible band of opalescent material, presumably cellular membrane fragments, is present in the position of pool *A*. To show that pool *A* contains membrane components, cultures of *E. coli* P678-54 harbouring ColEl were labelled with ^{3}H-leucine or [2-^{3}H]glycerol, which are incorporated into protein and membrane phospholipid, respectively[14]. Minicells were purified from these cultures and treated exactly as before, except the cells were not labelled with ^{3}H-thymidine. It was found (data not shown) that 17% of the total ^{3}H-leucine in the lysed minicells is located in the 1.35 g ml^{-1} density region in the caesium chloride–sucrose gradient. In addition, 100% of the phospholipid label reached equilibrium at a density of 1.35 g ml^{-1}. Therefore, the observed isopycnic density of the ^{3}H-ColEl DNA is most probably accounted for by the association of the plasmid DNA with membranous components.

Purified supercoiled, open circular, or linear ^{14}C-ColEl DNA was added to the lysate at various stages of the lysis procedure. Figure 1*a* shows that supercoiled ^{14}C-ColEl DNA does not appear in the pool *A* region of the gradient, suggesting that little or no ^{3}H-ColEl DNA from the minicell lysate aggregated nonspecifically to components in this peak. Similar results occurred with purified circular and linear ^{14}C-ColEl DNA. As shown in Fig. 1*b*, when pool *A* was dialysed and centrifuged a second time on a caesium chloride–sucrose gradients, approximately 50% of ^{3}H-ColEl DNA in pool *A* remained near the top

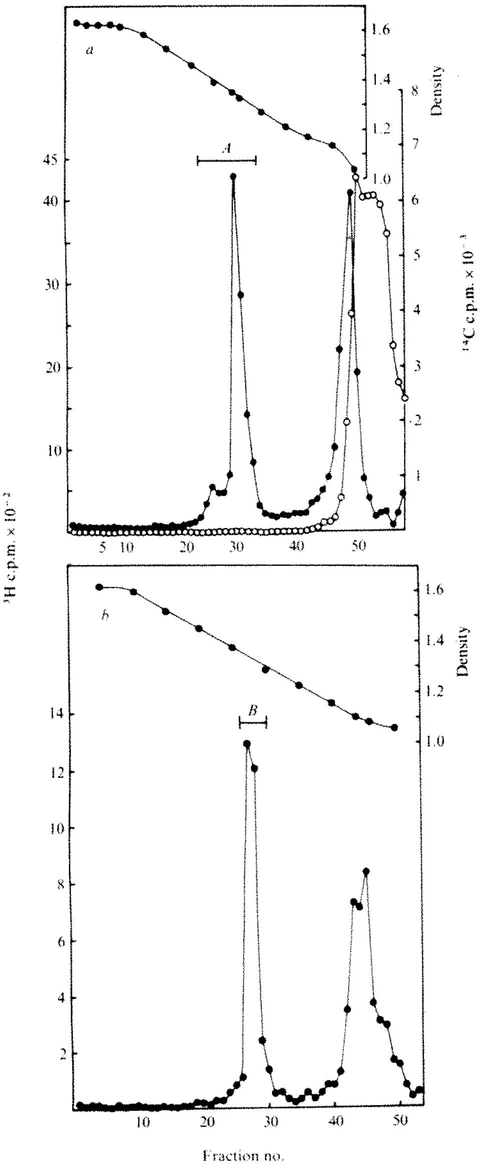

Fig. 1 Caesium chloride–sucrose gradients of lysates of minicells containing ^{3}H-labelled plasmid ColEl DNA. *a*, *E. coli* minicell producing strain, P678-54, Thy^{-}, carrying plasmid ColEl was grown to late exponential phase in 3 l of LB medium. The culture was centrifuged at 1,500 r.p.m. for 3 min in a Sorvall GSA rotor and the supernatant pelleted at 8,000 r.p.m. for 10 min, followed by resuspension in BSG (0.85% NaCl, 0.03% KH_2PO_4, 0.06% Na_2HPO_4, 0.1% gelatin). The resuspended minicells were layered on 33 ml 5–20% sucrose gradients and centrifuged in an HB4 rotor at 4,500 r.p.m. for 15 min. The minicell band was removed, diluted with BSG, pelleted, and again centrifuged on 5–20% sucrose gradients. This was repeated 2 or 3 times until *E. coli* whole cells could no longer be seen in the minicell preparation by light microscopy. ColEl DNA in the purified minicells was labelled with ^{3}H-thymidine by incubation for 30 min at 37 °C in 25 ml of M9 medium containing 0.1% vitamin-free casamino acids, 0.2% glucose, 20 μg ml^{-1} thiamine, 50 μg ml^{-1} tryptophan, 0.002 M cyclic AMP and 2 μg ml^{-1} each of adenosine, deoxyadenosine, guanosine, deoxyguanosine, cytosine, deoxycytosine and uridine, and 1 mCi of ^{3}H-thymidine. Incorporation of ^{3}H-thymidine into trichloroacetic acid-insoluble material was linear up to 90 min. After labelling, the minicells were centrifuged and resuspended in 2 ml of 0.75 M sucrose. Purified ^{14}C-thymine-labelled ColEl supercoiled DNA was added immediately after sucrose as a control for nonspecific association of ColEl DNA with membrane components. The mixture was incubated for 15 min on ice with 100 μg ml^{-1} lysozyme and 0.01 M EDTA, after which Triton X-100 was added to 0.05%. The lysate was layered on a preformed linear gradient of 5 M caesium chloride plus 20% sucrose to 0.5 M caesium chloride plus 10% sucrose made in TES (0.1 M Tris, *p*H 8.0, EDTA, *p*H 8.0, 0.5 M NaCl, 0.005 M) and centrifuged in an SW 27 rotor at 22,000 r.p.m. at 4 °C for 30 min[12]. Fractions were collected from the bottom, portions counted, and the refractive index of each fraction determined. The density was determined from caesium chloride–sucrose standard curves of density against refractive index. ●, ^{3}H radioactivity; ○, ^{14}C radioactivity. *b*, Pool A from the caesium chloride–sucrose in *a* was dialysed against TES and centrifuged on a caesium chloride–sucrose gradient in the same conditions as above.

of the gradient. Dialysis and centrifugation of pool *B* (Fig. 1*b*), again in the same conditions, does not result in any loss of ColEl DNA from the 1.35 g ml^{-1} density region, indicating that the remaining 20–25% of the total radioactivity incorporated into ColEl DNA (pool *B*) is stably associated with membrane material. In different experiments the percentage of total ^{3}H-thymidine incorporated into ColEl DNA found in pool *A* (Fig. 1*a*) varied, but the percentage of incorporated ^{3}H-thymidine remaining in pool *B* (Fig. 1*b*) was usually 20–25%. The released ^{3}H-ColEl DNA near the top of the gradient may represent plasmid DNA either specifically but weakly associated with membrane components or nonspecifically-associated DNA that is released during handling.

As a further test of the stability of ^{3}H-ColEl DNA membrane association, pool *B* was subjected to various treatments. It was found that ColEl DNA can be released from membrane material, as determined by a change in density of the ^{3}H-DNA in caesium chloride–sucrose gradients, by treatment with pancreatic DNase or the ionic detergents Sarkosyl and SDS (0.2%). Treatments that did not release the plasmid DNA included exposure of 2M NaCl, Triton X-100 (0.2%), pancreatic RNase (1 mg ml^{-1}), phospholipase A, freezing to −20 °C, and heating to 60 °C for 10 min. Treatment with pronase or heating at 100 °C for 10 min. gave variable levels of dissociation of the complex.

ColEl DNA–membrane complexes from pool *B* (Fig. 1*b*) and mini-ColEl-Km (pML21) DNA–membrane complexes from similar preparations were examined by electron microscopy.

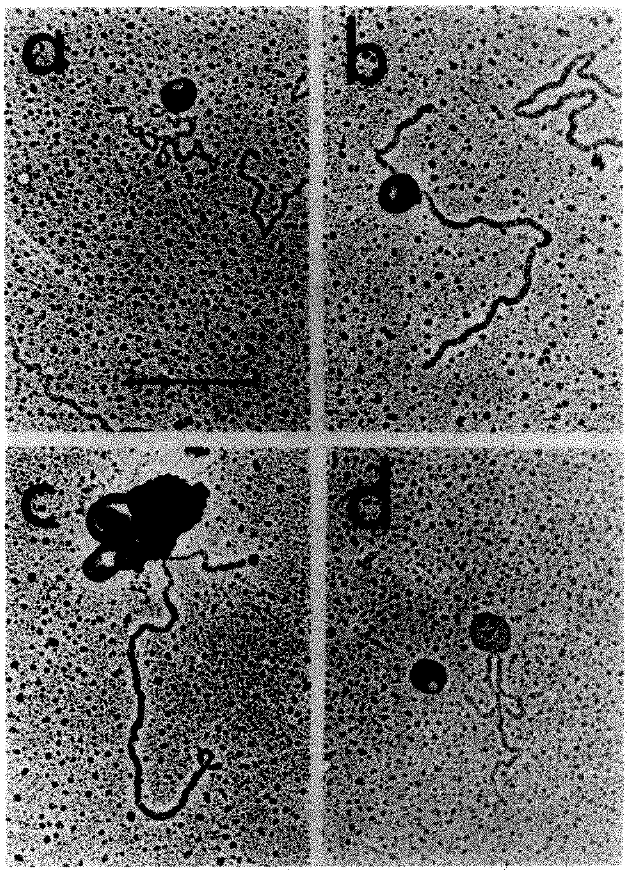

Fig. 2 Electron micrographs of *Eco*RI-cleaved ColEl DNA–membrane complexes and mini-ColEl DNA–membrane complexes. Minicells containing ColEl DNA or mini-ColEl-Km DNA were purified, labelled, lysed and centrifuged on caesium chloride–sucrose gradients as described in Fig. 1. Fractions corresponding to Pool *B* in Fig. 1 were dialysed against TES. Aliquots were adjusted to 10 mM $MgCl_2$ and either incubated at 30 °C for 30 min as controls for nuclease contamination or incubated at 30 °C for 30 min with *Eco*RI. Control and cleaved samples were spread for electron microscopy as previously described[16]. Purified open circular ColEl DNA was spread with the samples as a size reference. a, Supercoiled ColEl DNA–membrane complex; b, c, *Eco*RI-cleaved ColEl DNA–membrane complex; d, *Eco*RI-cleaved mini-ColEl DNA–membrane complex. The bar in frame a is equal to 0.5 μm.

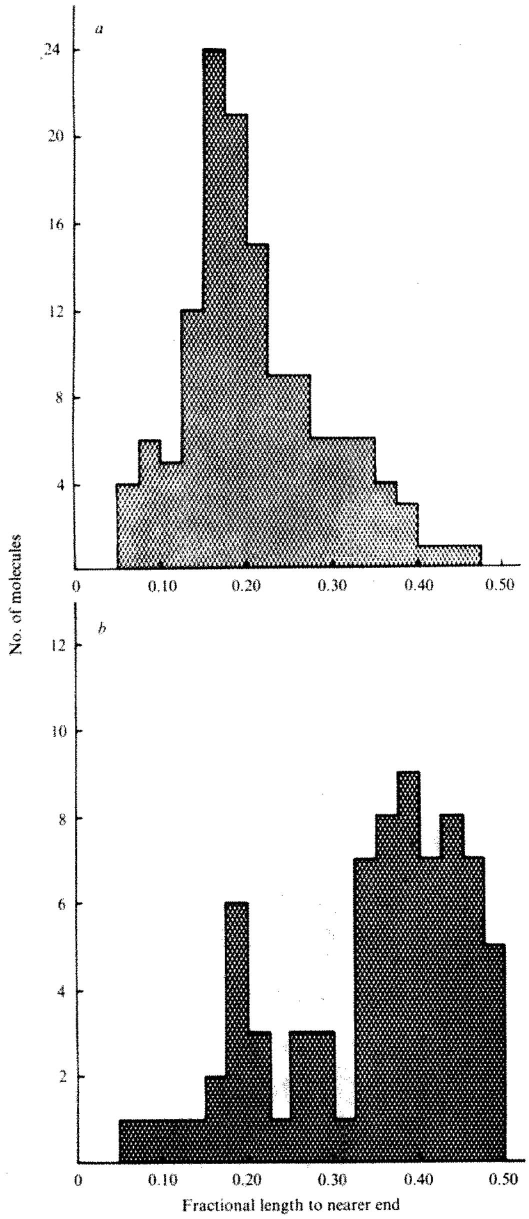

Fig. 3 Histogram of locations on *Eco*RI-cleaved ColEl DNA and mini-ColEl DNA in contact with a membrane fragment. Samples of purified ColEl DNA or mini-ColEl–Km DNA analogous to pool *B* of Fig. 1 were cleaved with *Eco*RI and visualised by electron microscopy. Molecules were measured in relation to purified circular ColEl DNA spread on the same grid, and only molecules that were of unit length were considered for analysis. Measurements were made on the short arm of the restricted DNA from the *Eco*RI site to the membrane fragment. Molecules with large membrane fragments covering the DNA in more than one of the arbitrary divisions of 0.025 molecular length were included in the histogram in each division in contact with membrane material. *a*, ColEl DNA; *b* mini-ColEl–Km DNA.

Figure 2 shows complexes before and after cleavage by *Eco*RI restriction endonuclease. This analysis usually showed some membrane-like fragments free from DNA in addition to supercoiled, open circular, and, in the case of restricted samples, linear plasmid DNA membrane complexes. Over 50% of the linear ColEl DNA observed was associated with a membrane fragment. A low percentage (<5%) of the membrane-bound ColEl DNA had two fragments attached. Most DNA-bound membrane fragments appeared vesicular and seemed to be of two general types (Fig. 2*a*, *b*, *d*). These fragments were about 0.1 μm in diameter. Other larger fragments could also be seen (Fig. 2*c*). When pool *B* was treated with 0.2% Sarkosyl and dialysed before preparation for electron microscopy, membrane-like structures could not be seen. As mini-ColEl-Km DNA has two *Eco*RI restriction sites, restricted preparations showed two molecules, the 4.5×10^6-dalton Km restriction fragment and the 2.2×10^6-mini-ColEl plasmid. Less than 3% of the Km DNA fragment possessed an attached membrane fragment. However, a large proportion of the mini-ColEl DNA was associated with a membrane fragment.

The total lengths of the linear molecules associated with membrane fragments derived from *Eco*RI-cleaved DNA of pool *B* were determined by electron microscopy. For ColEl DNA, only molecules that were the same length as open circular ColEl DNA spread on the same grid square were further analysed. For mini-ColEl only linear DNA molecules that were 1.2 μm in length when compared to the control ColEl molecules spread on the same grid square were further analysed. The location on the DNA molecule of the membrane fragments relative to the *Eco*RI restriction sites was measured. A total of 75 ColEl molecules from three different preparations and 50 mini-ColEl molecules from two different preparations were measured. Figure 3*a* and 3*b* represent, respectively, the number of ColEl and mini-ColEl molecules that had a membrane fragment in contact with the DNA within arbitrarily chosen divisions of 0.025 fractional length of the DNA molecule. If a membrane fragment was in contact with a DNA molecule in more than one of the divisions of 0.025 fractional length it was counted and plotted in each division. Some of the scatter and broadness of the histogram peaks may be due to nonspecific associations or to large membrane fragments that cover disproportionately large regions of the DNA molecules. As salt concentrations of ≥2 M will dissociate most DNA binding proteins[15], the caesium chloride–sucrose gradient conditions probably dissociate most weak associations.

Figure 3*a* indicates that about 60% of the ColEl DNA-bound membrane fragments are in contact with the DNA between 0.15–0.22 fractional length of the *Eco*RI restricted plasmid. This corresponds to the region of origin/terminus of replication and to the relaxation complex site of ColEl DNA. Figure 3*b* shows that about 55% of mini-ColEl DNA-bound membrane fragments are found at 0.33–0.45 fractional length of the *Eco*RI cleaved molecule. This is in the region of the origin of DNA replication of the mini-ColEl molecule (0.36–0.40 fractional length of *Eco*RI-cleaved mini-ColEl (R.B.S. and R. Eichenlaub, unpublished). Although this analysis does not distinguish between the two ends of the DNA molecules, the close correspondence to the origin of replication suggests a direct involvement of membrane components in plasmid ColEl DNA replication. The failure to isolate mini-ColEl DNA in the form of relaxation complex[13] may indicate in the case of this plasmid that the association with the membrane material is more a property of the origin/terminus of replication or the relaxation complex site of nicking than of the active relaxation complex proteins.

A peptide resembling COOH-terminal tetrapeptide amide of gastrin from a new gastrointestinal endocrine cell type

THE gastrointestinal hormones gastrin and cholecystokinin (CCK) share identical COOH-terminal sequences. In both hormones the COOH-terminal tetrapeptide amide constitutes the biologically active region, and the rest of the two molecules determines their potency and selectivity for different target cells. Their similarity in structure and activity may reflect a common phylogenetical origin[1]. The COOH-terminal tetrapeptide amide is highly immunogenic in each hormone and many gastrin antisera are specific for this sequence and also bind CCK. In order to study the hormones by immunocytochemistry and radioimmunoanalysis, antisera specific for several distinct sequences must be used. Previously, we have used such antisera to characterise antral gastrin cells and intestinal cholecystokinin cells by immunocytochemistry[2]. We now report the identification of three distinct types of gastrointestinal cells which show COOH-terminal gastrin (or CCK) immunoreactivity. One type corresponds to gastrin-producing G cells, another to CCK-producing I cells and a third type to TG cells which react only with antisera against the COOH-terminal tetrapeptide.

Specimens from the gastrointestinal tract of monkeys ($n = 5$) and pigs ($n = 10$) were studied by immunocytochemistry and correlative electron microscopy. The antisera used included As. 1295, 2717 and 4562, raised in rabbits against synthetic human gastrin-17, As. 4710 raised in a rabbit against the synthetic mid-portion (6–13) of human gastrin-17, As. 4478 raised in a guinea pig and As. 4698 raised in a rabbit against porcine CCK-33. As previously documented[1,2] As. 1295 recognises the NH_2 terminus of human gastrin-17, As. 4710 the mid-portion of human gastrin-17, As. 4562 and 2717 bind the COOH-terminal tetrapeptide portion of both gastrin and CCK, As. 4698 binds the region (25–30) of triacontatriapeptide CCK (CCK-33) and so also recognises octapeptide CCK (CCK-8) and caerulein, and As. 4478 binds the region (19–25) of CCK-33 and does not recognise CCK-8. The region-specificity of the antibodies is

Fig. 1 The amino acid sequences of porcine CCK-33 and gastrin-34 and the region-specificity of the antisera used in this study.

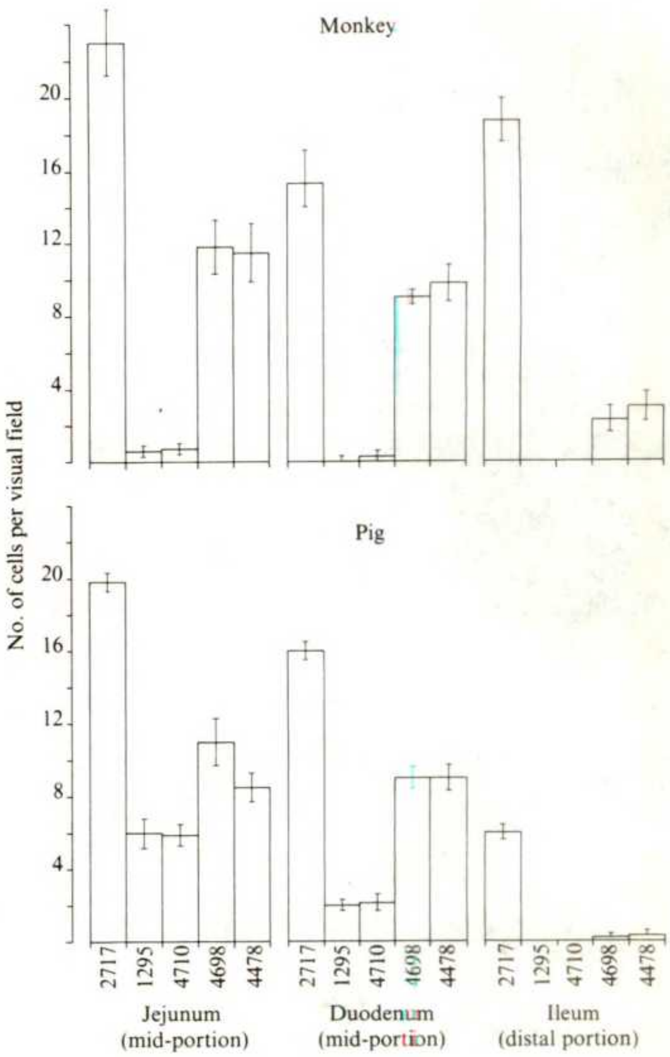

Fig. 2 Frequency distribution of intestinal endocrine cells reactive with COOH terminus-specific (Abs 2717 and 4562), CCK-specific (Abs 4478 and 4698) and gastrin-specific (Abs 1295 and 4710) antibodies. Note that in all parts of the small intestines the number of COOH terminus-reactive cells exceeds the number of gastrin and CCK cells. This difference reflects the number of TG cells. Pig ($n = 10$) material was collected at a nearby abattoir and green monkeys ($n = 5$) were anaesthesised with Mebumal (pentobarbital). Specimens from the gastrointestinal tract were frozen in melting Freon-22, freeze-dried, vapour-fixed in paraformaldehyde and embedded in paraffin. Serial 3-μm sections were reacted with antibodies detecting the COOH terminus (Abs 2717 and 4562), the 6–13 region (Ab. 4710) and the NH_2 terminus (Ab. 1295) of human gastrin-17 as well as antibodies detecting regions 19–25 (Ab. 4478) and 25–30 (Ab. 4698) of porcine CCK-33 (ref. 1). The antisera were immunoabsorbed and then stained as described previously[1,2]. Specificity was checked by conventional staining controls and by absorptions against synthetic human gastrin-17, the synthetic mid-portion (6–13) of human gastrin-17, pentagastrin, 99% pure porcine CCK-33, caerulein and other gut peptides[1,2]. The site of antigen–antibody reaction was revealed by the peroxidase–antiperoxidase (PAP) procedure of Sternberger or by immunofluorescence[7]. For quantitation, serial sections were stained with the different antisera (PAP technique only), so that the first and last slides in one series were stained with the same antiserum. The variation between these two slides never exceeded, and was usually considerably below, 5%. Only perfectly transverse sections were counted and the results were evaluated as numbers of cells per field of vision (objective × 10, eye-piece × 12.5) or as absolute figures (data not shown), The total surface area of the (mucosal) sections averaged 0.25–0.5 cm^2. The number of cells was always counted in corresponding adjacent visual fields.

Fig. 3 Electron micrographs and size distribution histograms of cytoplasmic granules in *a*, gastrin (G) cells; *b*, CCK (I) cells; and *c*, TG cells of green monkeys. Note the differences in size and morphology of the three granule types. (×7,100). Specimens from the antropyloric and duodenal mucosa of green monkeys ($n = 3$) were fixed by immersion for 15 min at 4 °C in a 2% glutaraldehyde: 3% formaldehyde solution in 0.1 M sodium phosphate buffer *p*H 7.3. After washing in buffer and osmication the specimens were embedded in Epon 812 and adjacent semithin and ultrathin sections were cut. Semithin sections were deplasticised and de-osmicated and permitted to react with the region-specific antisera[8] (see Fig. 1). The site of antigen–antibody reaction was revealed by immunofluorescence and immunoreactive cells were identified in the adjacent ultrathin sections. Controls were as described in Fig. 1.

shown schematically in Fig. 1. As. 1295, 4710, 4698 and 4478 contained additional populations of COOH terminus-reactive antibodies which were removed by immunoabsorption against either CCK-33 (As. 1295 and 4710) or synthetic human gastrin-17 (As. 4698 and 4478). Following the immunoabsorption step the sequence-specificity of the antibodies was verified by absorptions against synthetic human gastrin-17, the synthetic (6–13) region of human gastrin-17, pentagastrin (Peptavlon) synthetic caerulein and 99% pure porcine CCK-33 and by the inability of As. 4698 and 4478 to react with antral gastrin cells, by the inability of As. 1295 and 4710 to react with intestinal CCK cells and by the ability of As. 4562 and 2717 to demonstrate both gastrin and CCK cells, as reported elsewhere in detail[1,2]. Our immunocytochemical results were quantitied as described in Fig. 2.

Use of gastrin-specific antisera (As. 1295 and 4710) revealed that gastrin cells predominated in the antropyloric mucosa and were few in the small intestines (Fig. 2). The oxyntic mucosa of the stomach, the Brunner glands of the duodenum and the distal ileum only occasionally contained gastrin cells (Fig. 2). The colon was devoid of such cells.

The CCK-specific antisera (As. 4698 and 4478) demonstrated numerous endocrine cells in the duodenum and jejunum. The proximal ileum contained a few scattered CCK cells, whereas the stomach, the duodenal glands of Brunner and the distal ileum were devoid (monkeys) or nearly devoid (pigs) of such cells (Fig. 2).

The COOH terminus-specific antisera (As. 2717 and 4562) demonstrated both gastrin and CCK cells, as well as a third population of intestinal endocrine cells, which failed to react with the gastrin- or CCK-specific antisera. The existence of the third cell population was inferred from the finding that the COOH terminus-specific antisera demonstrated many cells in both the Brunner gland area and in the distal ileum. Cell counts (Fig. 2) verified the existence of the third cell type, the sum of COOH terminus-reactive cells greatly exceeding the sum of gastrin and CCK cells. Thus, COOH terminus-reactive cells, distinct from gastrin and CCK cells (TG cells), were few in the antropyloric mucosa and numerous in the small intestines. They were particularly well represented in the Brunner glands of the duodenum and in the distal ileum, areas in which gastrin and CCK cells were virtually absent (Fig. 2). TG cells were not detected in the oxyntic mucosa or in the colon.

Identification of gastrin, CCK and TG cells by electron microscopy was carried out in the monkey antropyloric and duodenal mucosa using the region-specific gastrin and CCK antibodies. Antral gastrin cells were characterised by the presence of numerous cytoplasmic granules of variable electron density. Most granules contained an irregular dense core and measured 221–442 nm (mean 307 nm, see Fig. 3). The cells reached the lumen through an apex endowed with microvilli, and contained organelles typical of peptide- or protein-synthesising cells. This ultrastructure is similar to that of G cells in other species[3,4].

Duodenal CCK cells were elongated or flask-shaped and contained numerous membrane-bound granules with a thin electron-lucent halo separating the highly electron-dense core from the membrane. The granules were round or slightly angular and measured 128–383 nm (mean 209 nm, see Fig. 3). Their ultrastructure is similar to that of the I cells of the small intestines, which have been shown to produce CCK[5].

The TG cells were identified in both the antropyloric gland area and in the duodenum. They contained large cytoplasmic granules with a core of medium to high electron density. A thin halo was usually present between the surrounding membrane and the dense core. The dense core, which almost completely filled the granules, was filamentous in texture and the granules measured 178–400 nm (mean 275 nm, see Fig. 3). The TG cells contained numerous microtubules and microfilaments and both free and membrane-bound ribosomes (Fig. 4). The ultrastructure of the TG cell is therefore quite distinct from that of gastrin-producing G cells and CCK-producing I cells, especially with respect to the morphology of the cytoplasmic granules.

As the distal half of the ileum of both pigs and monkeys contained many TG cells but very few gastrin and CCK cells, this part of the intestine was extracted in boiling water and/or acetic acid for radioimmunoassay[6]. As expected from immunocytochemical findings, only very low levels of immunoreactivity could be measured with gastrin-specific (As. 2604) and CCK-specific (As. 4698)[6] assays. Larger amounts of immunoreactivity were, however, detected by a COOH terminus-specific assay with As. 2609[6]. Gel chromatography of ileal extracts, monitored by CCK-, gastrin- and COOH-terminal-specific assays revealed low concentrations of immunoreactivity in positions corresponding to CCK-8, gastrin-34 and gastrin component I. Gastrin-17-like immunoreactivity was not detectable. In contrast, considerable amounts of immunoreactivity eluted in the position corresponding to the COOH-terminal tetrapeptide amide of gastrin (Fig. 5). This component has not yet been shown to be identical with the true COOH-terminal tetrapeptide amide, but in parallel studies on the porcine antropyloric mucosa (to be published elsewhere) strong evidence for the existence of this component was obtained.

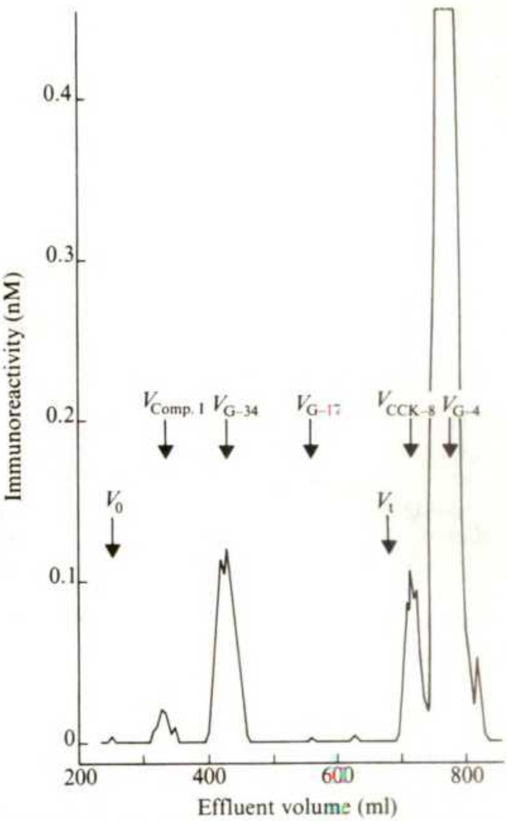

Fig. 5 Gel chromatography of a boiling-water extract of mucosa from the midsegment of the porcine ileum. 6 ml extract was applied to a Sephadex G-50 superfine column (25 × 2,000 mm) eluted at a flow rate of 20 ml h^{-1} with 0.25 M NH_4HCO_3, *p*H 8.2 at 4 °C. The column was calibrated with ^{125}I-albumin (void volume (V_0)), highly purified porcine gastrin component I ($V_{comp.I}$), gastrin-34 (V_{G34}), gastrin-17 (V_{G17}), CCK-8 (V_{CCK8}), highly purified synthetic gastrin tetrapeptide amide (V_{G4}) and ^{22}NaCl (total volume (V_t)). In addition to boiling water, midsegments of porcine ileum were also extracted (0.1–0.2 g mucosa ml^{-1}) with 0.5 M acetic acid, acetone (Merck), and acetone acidified with 0.1 M HCl (100:3, *p*H 1.0). However, when measured with an assay specific for the common COOH-terminal sequence of gastrin and CCK (antiserum 2609, also used to monitor the gel chromatography as shown) the latter procedures extracted <8% of the immunoreactivity measured in boiling-water extracts. Using boiling water extraction the following concentrations of immunoreactive gastrin-CCK-like peptides were found in mucosa from mid-ileum: Component I, ~0.2; gastrin-34, 2.3 ± 1.1; gastrin-17, <0.2; CCK-8, 14 ± 6; gastrin-4, 113 ± 7 (pmol per g mucosa wet weight; mean ± s.e.m., $n = 3$).

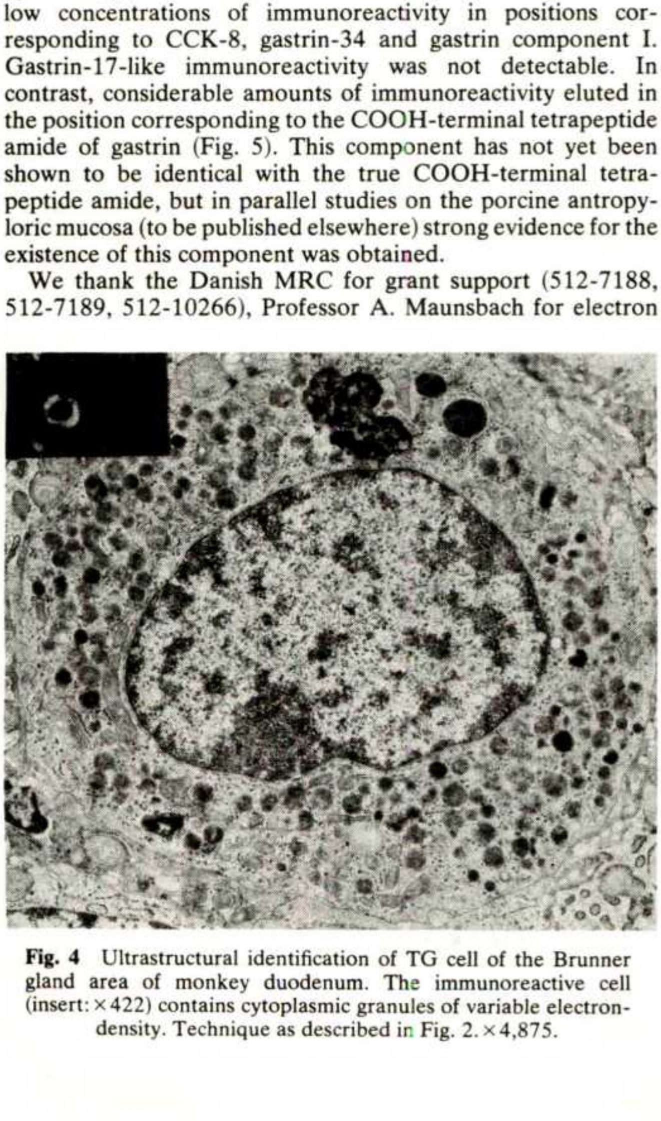

Fig. 4 Ultrastructural identification of TG cell of the Brunner gland area of monkey duodenum. The immunoreactive cell (insert: × 422) contains cytoplasmic granules of variable electron-density. Technique as described in Fig. 2. × 4,875.

We thank the Danish MRC for grant support (512-7188, 512-7189, 512-10266), Professor A. Maunsbach for electron microscope facilities, Mrs J. B. Lauridsen and Mrs E. Petersen for technical assistance and Drs J. H. Walsh, J. Morley and Professor V. Mutt for antibody 1295 and natural and synthetic peptides.

Note added in proof: Recently, Buchan *et al.*[9] described the ultrastructure of the intestinal gastrin cell. These small-granulated, D_1-like cells seem to be more numerous in the human than in the porcine or simian small intestines. Their ultrastructure is similar to that of small-granulated, gastrin immunoreactive cells described by us in human fetal duodenum[10] and in rat antropyloric mucosa (G_a cells[11]). Thus, the small intestines harbour three types of cells producing related peptide hormones: CCK (I) cells, COOH-terminal tetrapeptide amide (TG) cells and intestinal gastrin (GI) cells. The main cell type in the antrum is the G (gastrin) cell, but some species in addition contain small numbers of TG cells (monkeys) and G_a cells. The G_a cell may possibly be the murine equivalent of GI cells.

Protein structural fluctuations during a period of 100 ps

A RECENT 9-ps molecular dynamics simulation[1] of the bovine pancreatic trypsin inhibitor (PTI) at 295 K revealed a rich variety of motional phenomena at the atomic level on a picosecond time scale. To obtain information about longer time processes, and to characterise more accurately the short time results, a 96-ps dynamical simulation of PTI at an average temperature of 306 K has been completed with the techniques used previously[1]; an extended equilibration period of 72 ps before simulation served to eliminate internal stresses. Analysis of the present simulation has confirmed most of the conclusions of the earlier study but has shown in addition that there are significant features of the dynamics that can be observed only over a longer period, ~100 ps.

An overall measure of the correspondence between the time-average dynamical and X-ray structures[2] is given by the radius of gyration. It equals 10.22 Å (with fluctuations of ±0.1 Å) for the former and 10.96 Å for the latter. The primary source of difference between the two are the positions of the charged external side chains, which may in fact have different average positions in solution and in the crystal[3,4]. The dynamics simulation also shows a strong coupling between the amino and carboxyl termini, in agreement with NMR solution results[5] but different from the crystal structure (see Fig. 1 of ref. 1). The core of the protein has a heavy-atom number density close to the X-ray value; within a radius of 8 Å from the protein centre, the calculated number density is 0.063 Å^{-3}, compared with 0.060 Å^{-3} for the X-ray structure.

Analysis of individual atom position fluctuations shows that, as a result of the more careful equilibration, they are slightly smaller than in the previous simulation. The average r.m.s. fluctuation for the α carbons is 0.60 Å (previously 0.74 Å) and that for all atoms 0.75 Å (previously 0.90 Å); the corresponding X-ray results from isotropic temperature factors are 0.68 Å and 0.74 Å, respectively (J. Deisenhofer, personal communication). The calculated mean-square positional fluctuations are found to be highly anisotropic for most of the atoms. For the α carbons, the overall averages are $\langle z^2\rangle = 0.252$ Å^2, $\langle x^2\rangle = 0.051$ Å^2 and $\langle y^2\rangle = 0.099$ Å^2, where a local principal axis system is used for each atom; in some cases, the largest component is more than 10 times the smallest. The differences in the orientations of the local systems for atoms in the same region, relative to a space-fixed axis system, make clear that the anisotropy is reflecting structural constraints rather than overall protein motion. Evaluation of the positional distribution functions shows that many of them differ significantly from the standard gaussian form, a consequence of the fact that the potential of mean force experienced by the atoms is not harmonic.

Because of their well-defined nature and possibility for direct experimental investigation, the aromatic side chain motions in PTI were studied in detail[6]. Tyrosine ring orientation fluctuations of ±30° from the average (r.m.s. value of 12°) were found for residues in the interior of the protein; this corresponds to a torsional potential of mean force considerably softer than that of the rigid protein. The time-dependence of the torsional motion approximates that expected from a Langevin equation for an angular oscillator with near critical damping; the calculated relaxation times for this motion are of the order of tenths of ps; for example, for Tyr 21 it is 0.2 ps. Comparison between the tyrosine side chain in a dipeptide and in the protein clearly demonstrates the importance of matrix damping effects due to the surrounding atoms in the latter.

An important result of the new simulation is the presence of long-lived fluctuations in the properties of PTI. Making use of 1-ps dynamic averages ('coarse-graining') to damp out rapid oscillations, it was found that fluctuations of 5–15 kcal mol^{-1} with a duration of 2–15-ps occur in the potential energy associated with the bond-stretching and bond-angle-bending coordinates, as well as with the non-bonded interactions. It seems that these energy fluctuations represent transitions of the protein from one potential minimum to another in the neighbourhood of the time-averaged structure. Direct evidence for this is given by the correlation of the potential energy fluctuations with transitions between minima of side chain dihedral angles and other internal coordinates.

A consequence of the infrequent structural transitions is that long periods of averaging are required to establish the fluctuations in global properties. Using the entire 96-ps period, we find the r.m.s. fluctuation in the kinetic energy to be 11.51 ± 0.1 kcal mol^{-1}, which yields a classical heat capacity of 3.14 ± 0.1k per protein atom (k is the Boltzmann constant). The previous simulation resulted in a smaller value for the r.m.s. kinetic energy fluctuation (9.3 kcal mol^{-1}) and a correspondingly smaller heat capacity (2.3 k per atom); test calculations show that such low values are due to the short time interval used for averaging. Apparently the heat capacity contains a contribution from equilibration among the different available states and so cannot be related as simply to models for protein dynamics as assumed in ref. 1. Long-lived fluctuations also occur in the atom positions, so that values obtained by averaging over less than 10 ps tend to be too low; for example, for the α carbon atoms, the r.m.s. fluctuation from 2-ps intervals are ~0.40 Å as compared with the value of 0.60 Å for the complete simulation.

The present calculation supports the earlier conclusion that a dynamic simulation can provide realistic and highly informative descriptions of the detailed atomic motions in the interior of a protein. The existence of large fluctuations in the structure and energy components indicates that the properties of proteins result from the occupation of a variety of thermally accessible states, even for times as short as 10–100 ps. It will be of interest to assess the role of these states in the biological activity of proteins and to determine the importance of alterations in the available states and transitions among them due to the solvent environment and ligand or substrate binding.

A full account of the extended simulation will be presented elsewhere. We thank John Ramsdell, Barry Olafson, and Thomas Jordan for their assistance and the NIH for support. J. A. McC. thanks the NIH for a postdoctoral fellowship.

Note added in proof: Frauenfelder, Petsko, and Tsernoglou (personal communication) have recently determined isotropic temperature factors for myoglobin at a series of temperatures and have used them to obtain atomic positional fluctuations; a dynamical simulation to compare with their results is in progress.

In recent years, there has been growing recognition of the pivotal importance of trace elements in all areas of biological, environmental, and biomedical research. Many trace elements are now known to be essential for life. Others are dangerous toxicants and pollutants. And some are both essential to various plant and animal species at certain intake levels, and poisonous to the same or other species at different levels of ingestion.

Because original research papers dealing with trace elements have been widely disseminated throughout the primary journal literature, ***Biological Trace Element Research*** has been established to serve as the new and much-needed central forum for this powerfully emergent, interdisciplinary field. Its concentration will be on investigations of individual elements rather than on methodology or narrow discipline-oriented work as such. Not a biochemical journal *per se*, Biological Trace Element Research will emphasize the integrative aspects of research in these fields, relating human and animal nutritional studies not only to the fundamental chemistry and biochemistry at issue, but also to the elucidation of the relevant aspects of preventive medicine, epidemiology, clinical chemistry, agriculture, endocrinology, animal science, pharmacology, microbiology, toxicology, virology, marine biology, sensory physiology, developmental biology, and so on.

Call for Papers/Instructions to Authors

Three copies of all manuscripts submitted for consideration should be sent either to the Editor-in-Chief, G. N. Schrauzer, or to one of the Editors. Authors from the Eastern Hemisphere (Australia, New Zealand, Japan, India, Hong-Kong, etc.) may find it preferable to send their manuscripts to Dr. E. J. Underwood, University of Western Australia, Nedlands, WA, 6009.

The original manuscript should be complete with tables, references, footnotes, charts, figures and legends, and must be written in English. All material must be typed double-spaced on one side of consecutively numbered 8½ × 11″ pages, and should be concise and consistent in style, spelling, and the use of abbreviations. The first page of each manuscript should provide the Title of the article, the Authors' Names (without degrees), the authors' Affiliations, a running title (not exceeding 40 letters and spaces), and an asterisk identifying the author to whom proofs, reprint requests, and other correspondence should be directed.

Authors are strongly encouraged to use descriptive headings in this order: Abstract, Key words, Introduction, Methods, Results, Discussion, Conclusions, Acknowledgements, and References. References should be cited in the text by italic numerals in parentheses, and should generally follow ACS Handbook style. Abbreviations of journal titles should follow the style used in *Chemical Abstracts's Service User Index*, 1969 Edition.

NATO CONFERENCE SERIES

The six NATO Conference Series focus on a variety of contemporary issues of primary concern to nations worldwide in the areas of Ecology (I), Systems Science (II), Human Factors (III), Marine Sciences (IV), Air–Sea Interactions (V), and Materials Science (VI)

Series I: Ecology

Volume 3: The Breakdown and Restoration of Ecosystems

edited by M. W. Holdgate and M. J. Woodman

Experts in the field examine the extent of man's destruction of ecosystems in northern temperate zones, identify basic ecological principles for their protection and rehabilitation, and consider guidelines for avoiding future devastation while ensuring optimal use of natural resources 508 pp, 1978, $30 00 ($36 00/£18 90 outside U S)

Series II: Systems Science

Volume 7: Manpower Planning and Organization Design

edited by Donald T. Bryant
and Richard J. Niehaus

Examines the intricate relationship between systems science and the behavioral sciences, emphasizing the optimization of overall systems objectives, individual career aspirations, and the socioeconomic policies of regions, countries, and other large aggregates 804 pp, 1978, $65.00 ($78 00/£40 95 outside U.S)

Series III: Human Factors

Volume 9: Event Related Potentials in Man

Applications and Problems

edited by Dietrich Lehmann
and Enoch Callaway

This volume presents a multidisciplinary selection of recent papers covering such topics as evoked potential in the diagnosis of neuropathology, adaptation effects, ERP scalp topography and a wide presentation of other physiological and psychological topics approx 500 pp, 1979, $39 50 ($47 40/£24 89 outside U S)

Volume 8: Mental Workload

Its Theory and Measurement

edited by Neville Moray

This volume examines mental workload from both an academic and applied viewpoint Strengths and weaknesses of contemporary approaches to workload are described and new methods of measurement are critically assessed In addition, *Mental Workload* indicates areas where further research is needed, and offers cognizant interdisciplinary discussions, as well as extensive reviews from each discipline in a form readily understood by workers in other areas. 512 pp, 1979, $37 50 ($45 00/£23 63 outside U S.)

Series IV: Marine Sciences

Volume 3: Spatial Pattern in Plankton Communities

edited by John H. Steele

This volume applies the most recent knowledge from physical and biological oceanography in attempting to describe plankton "patchiness" Specific topics include improved methods of sampling for different time–space scales, spectral analysis and particle counting, and the use of relevant concepts from terrestrial ecology 480 pp, 1978, $42 00 ($51 00/£26 78 outside U S)

Introducing two new
NATO Conference Series

Series V: Air–Sea Interactions

This series will constitute an ongoing examination of various aspects of air–sea interaction studies, presenting the most recent advances in research and practice in specially selected subject areas of major interest

Volume 1: Turbulent Fluxes through the Sea Surface, Wave Dynamics, and Prediction

edited by A. Favre and Klaus Hasselmann

Stressing the importance of combining flux and boundary layer inquiries with wave-dynamical investigations, this volume reviews recent advances in the predication of sea states and the determination of atmospheric and oceanic circulation through fluxes of energy, mass, and momentum 692 pp 1978, $49 50 ($59 40/£31 19 outside U S)

Series VI: Materials Science

Taking a broad, interdisciplinary perspective this series will present a wide range of topics of current interest in the material sciences

Volume 1: Molecular Metals

edited by William E. Hatfield

This first volume in *Materials Science* analyzes the current status of research and development in the design, synthesis, and characterization of materials which are formed from molecular precursors, and have high or metal-like electrical conductivity Included are summaries of intensive discussions with the aim of reaching a consensus on the potential of recent developments in this field approx 545 pp, 1979, $49 50 ($59 40/£31 19 outside U S)

Circle No. 14 on Reader Enquiry Card.

reviews

Some pioneers of Natural History

Ray Desmond

The Naturalists: Pioneers of Natural History. By A. C. Jenkins. Pp. 200. (Hamish Hamilton: London, 1978.) £6.95.

MAN has always had some interest in animals and plants, if for no other reason than that they provide him with food. But curiosity rather than necessity compelled the attention of people like Aristotle who was one of the earliest scientific observers of nature. His *Historia animalium* shaped and directed scientific thought and enquiry for centuries.

Mr Jenkins's survey of the lives and achievements of some of the pioneers of Natural History begins with Aristotle and Pliny, and he pauses to consider mediaeval bestiaries and herbals before introducing the first encyclopaedic systematist, John Ray. Ray's skill and industry in classifying animals and plants earned him the apellation, "the Aristotle of England". But he was to be overshadowed by the Swedish naturalist, Carl Linnaeus, as the supreme classifier of the many forms of life. Linnaeus's sexual classification of plants, based upon the number of stamens a flower possessed, provided the professional and amateur botanist with a delightfully easy method of identifying plants, although one naturalist, Johann Siegesbäck of St Petersburg, rejected it as a "lewd and licentious system".

Both great and lowly have been devotees of the study of Nature. Mr Jenkins records that Frederick II, King of Sicily and Emperor of Germany, became a passionate naturalist through falconry and created a number of zoological gardens. He could also have mentioned the Moghul Emperor, Babur, who even during his conquest of India had time to observe a handsome plant or an unfamiliar animal.

Natural History has always provided a useful role for the amateur. Sir Joseph Banks, perhaps the most influential of all amateur naturalists, discovered its delights while a student at Oxford and after graduating persuaded his mother to rent a house at Chelsea so as to be near the Physic Garden of the Society of Apothecaries. It is said he paid £10,000 for the privilege of accompanying Captain Cook as naturalist on his first circumnavigation of the world. He encouraged Sir James Edward Smith, another enthusiastic amateur, to buy Linnaeus's collection of plants, insects, shells, minerals and manuscripts. He despatched gardeners to many parts of the known world to collect new plants for the King's gardens at Kew and Windsor.

Plant collectors were often explorers in their own right, travelling through unknown lands and risking their lives at the hands of hostile natives. Mr Jenkins praises the fortitude of David Douglas, a gardener at Glasgow Botanic Gardens, who was sent to North America in 1823 by the Horticultural Society of London to collect plants. Always ill at ease in society, Douglas was happiest on his own in the wilds of Canada where he endured incredible hardships in his pursuit of plants. The observation of Nature meant everything to him. There was the occasion when, despite extreme hunger, he would not allow a Franklin's goose which had been shot to be eaten because he wanted it for scientific purposes. He was only 35 when he was trampled to death by an enraged bull in an animal pit in Hawaii.

Not all naturalists led such adventurous lives. The French entomologist, Jean Henri Fabre, never left his native Provence, and the Reverend Gilbert White found fulfilment in his acute observation of natural things at Selborne in Hampshire. Indeed many clergymen escaped from the tedium of parochial duties through a study of botany, ornithology, entomology or some other branch of Natural History.

Natural History has its share of eccentrics and Charles Waterton, squire of Walton Hall in Yorkshire, is one of the most endearing of them all. He spent ten years building a high wall around his estate to protect wildlife from foxes, badgers and poachers. In his *Wanderings in South America*, he describes his vain attempts to persuade the vampire bat to suck his blood, and his bare-back ride on an alligator is a classic ancedote. As a devout Catholic he could not resist using his considerable skills in taxidermy to create animal caricatures of leading Protestants. He ridiculed Darwin's evolutionary theory by fashioning a simian-like creature from the skin of a red howler monkey and solemnly announcing it was the missing link in man's evolutionary chain.

Of course Charles Darwin had to be given a chapter in this book but the author spares a few pages for his fellow evolutionist, Alfred Russel Wallace, who meekly, almost masochistically, allowed himself to be eclipsed by Darwin.

Towards the end of his work Mr Jenkins admits that it "would more accurately be subtitled 'Some pioneers of Natural History' presenting as it does no more than a handful of naturalists". It is an easy matter to point to omissions. The two great bird painters, Audubon and Gould, are included but there is no mention of any eminent botanical artists such as Ehret and Redouté. In fact the zoological interests of the author predominate. Much of the author's life has been devoted to the cause of animal conservation and he informs us rather sadly that even Audubon indulged in the wanton killing of birds. He is an active supporter of zoos and discusses their role in protecting endangered species.

Mr Jenkins writes with enthusiasm and conviction but not always with accuracy. There is a sprinkling of mistakes, some of them clearly the result of careless proof-reading. The Linnean Society was founded in 1788 not 1778 (p46); William Harvey died in 1657 not 1677 (p192); the drawing of a lupin on p96 comes from the *Botanical Register* and not the *Botanic* (sic) *Magazine*; George III's mother, Princess Augusta, was never Queen (p88). Why are only floruit dates given for Nicholas Culpeper, John Gerard and William Turner (pp191–93) when the dates of birth or death are known?

Compared with Joseph Kastner's *A World of Naturalists* (John Murray: London, 1978) and David Allen's *Naturalist in Britain: a Social History* (Allen Lane: London, 1976), Mr Jenkins's account is lightweight indeed. However, with its generous and well chosen selection of plates, some in colour, it can be recommended as a pleasant introduction to the subject. □

Ray Desmond is Deputy Keeper at the India Office Library and Records, and a Past President of the Society for the Bibliography of Natural History.

Assessment of medical technology

The Image and the Reality: A Case Study of the Impacts of Medical Technology. By B. Stocking and S. L. Morrison. Pp. 80. (Oxford University Press: Oxford, London and New York, 1978.) Paperback £3.

THERE is no doubt about the public appeal of medical technology, as the achievement of a remarkable lady in Lancashire is raising nearly £1·5 million to buy and run a body scanner attests. Yet as the Director-General of WHO has recently said: "Technology for the sake of technology is a dangerous addiction-producing drug". Stocking and Morrison tackle the problems of technology assessment taking the body scanner as a case study.

The development of computed tomographic (CT) scanning of the brain by EMI, funded by the Department of Health and Social Security, was a remarkable British success story leading to clear improvements in diagnosis The same technique—X-rays passed through the body, detected by scintillation counters coupled to a computer—was then extended to whole body scanning. Whereas clinical evaluation had accompanied development of the brain scanner, in the case of whole body scanners evaluation was more complex because of the variety of organs involved and of alternative diagnostic techniques and they were extensively introduced before there had been thorough clinical evaluation The most rapid diffusion of body scanners has taken place in the USA (700 machines by 1977) and is largely attributable to their profitability, whereas in Britain diffusion has been much slower (11 machines by 1977) and for most of these the capital, but not running, costs have been met by charities rather than the health service.

The impact of body scanners is considered in this book on three broad levels: for patients, in terms of diagnosis, patient management and outcome; for the health service, in terms of the pattern and demand for care and for the professions involved; and for industry involved in manufacturing the equipment. As assessment of any technology must be concerned with the future, the authors discuss a variety of changes that may affect the contribution of CT scanners such as future developments of CT scanners, advances in other imaging techniques and in therapy, changes in cost and health service expenditure. This of course introduces many uncertainties but it is surely wise to try and see what may develop and the implications; as decisions affect the future it makes little sense to base them solely on an evaluation of the past.

In assessing medical technology, what is ultimately most important is the effect on outcome for the patient. Randomised controlled trials are common, if far from universal, practice in evaluating new drugs and therapies—however unusual such trials may be in assessing accepted techniques and therapies—and there is every reason to extend them to diagnostic procedures. Yet this is only just beginning.

Stocking and Morrison write· "The remarkable diffusion of [whole body scanners] prior to proper clinical evaluation is unsatisfactory". This is perhaps an understatement. The image of the health service promoted by the medical profession in Britain and many other countries is that it is crumbling from lack of resources and deprived of new developments that could be saving lives. What may be closer to the reality is that much of the medical profession is quite unscientific, indifferent to clinical evaluation and infatuated with technology and that there are ample resources if only they can be re-directed from activities which are useless and downright harmful into those where they may do some good.

This slim volume is interesting as a case study, and one can only lament that it is the first such study to approach a new technology in a systematic and comprehensive way. It is still more valuable in that it poses fundamental questions about the nature of health services and the impact of technology on these—which is not to doubt the highly beneficial effects in many cases. Finally, the authors make a positive proposal for a Medical Technology Assessment Group. With the prospect of almost limitless extensions of what *can* be done with medical technology, decisions as to what *should* be done can only become more pressing. The sooner Departments of Health and the World Health Organisation regard the assessment of medical technology as central to their functions the more hope there is of shaping health services to conform with the needs of human life

David Piachaud

David Piachaud is Lecturer in Social Administration at the London School of Economics and Political Science.

Testicular function

The Mammalian Testis By R. B. Setchell. Pp. 450. (Paul Elek: London, 1978.) £18.

THE testis is responsible for the production of spermatozoa and testicular hormones. Highlights of spermatozoa production include the initial mitotic divisions, the setting aside of stem cells which will re-initiate the spermatogenic process at some later date, meiosis, and finally, the dramatic metamorphosis of the prospective gamete that results in the formation of the acrosome, flagellum and mitochondrial helix and in the condensation of nuclear chromatin. Interestingly, many of these events occur only if the prospective gamete is sequestered behind the blood–testis barrier formed by the Sertoli–Sertoli occluding junctions bathed in fluids rich in steroid hormones and protected from noxious stimuli such as elevated temperature and radiation.

Dr Setchell's book deals with all the above aspects of testicular function. This is a formidable task because it requires that the author be knowledgeable in anatomy, physiology, biochemistry and endocrinology. For the most part, Dr Setchell achieves this difficult task with the result that the book is informative, clearly written, well illustrated and completely referenced. It will provide a valuable source of information for all those interested in testicular structure and function.

The chapters on vascular and nervous supply of the testis and scrotum, on fluid secretion and entry of substances into the seminiferous tubules, and on testicular thermoregulation are extremely good and reflect the author's long-standing research interest and expertise on these subjects. The chapters on spermatogenesis, endocrinology of the testis and endocrine control of the testis are presented in a thorough and professional manner. The chapters dealing with testicular metabolism and naturally occurring and induced dysfunctions of the testis are informative but not insightful. They consist primarily of a recitation of literature references and contain little or no synthesis of concepts Overall, this is an excellent book and Dr Setchell should be congratulated.

Larry Ewing

Larry Ewing is Professor and Head of the Division of Reproductive Biology in the Department of Population Dynamics, Johns Hopkins School of Hygiene and Public Health, Baltimore, Maryland.

Physicochemical Aspects of Protein Denaturation
by **S. Lapanje**, *University of Ljubljana, Yugoslavia.*
Provides the first up-to-date account of protein denaturation to be advanced over the past eight years. It outlines physicochemical aspects, selecting and organizing material to accommodate readers of different educational and professional backgrounds. The approach is pragmatic, giving a concise and accurate review. Readers need only possess a knowledge of elementary physical chemistry and proteins. Accounts of experimental methods are self-contained and no consultation of specialized monographs is required. Particular attention has been paid to the macromolecular properties of unfolded (denatured) proteins, incorporating — in the tables — all important physicochemical data. And, although little unpublished material is included, several physicochemical aspects of protein denaturation have been submitted to a critical analysis; this holds especially true for the thermodynamic analysis of denaturation.
Careful reading of the book will lead to a real understanding of the phenomenon and do away with many misconceptions that can result from superficial or casual studies, and the indication of still unsolved problems should promote investigations into their solutions.
December 1978 344 pages
0471 03409 6 $40.00/£19.50

The Chemistry of Soil Constituents
edited by **D.J. Greenland**, *Department of Soil Science, University of Reading,*
and **M.H.B. Hayes**, *Department of Chemistry, University of Birmingham.*
A study of the chemistry of soils falls naturally into two sections — the static and the dynamic. This is the first of two companion volumes to deal with these two aspects of soil chemistry.
Contents: Foreword; Preface; Soils and Soil Chemistry; The Structure and Chemistry of Soil Clay Minerals; The Chemistry of Soil Organic Colloids; Surfaces of Soil Particles; Surface Electrolyte Interactions; Water on Particle Surfaces; Index.
December 1978 482 pages
0471 99619 X $55.00/£26.00

Saharan Dust — Mobilization, Transport, Deposition: SCOPE 14
edited by **C. Morales**, *Swedish Natural Science Research Council, Stockholm, Sweden.*
Scientists have recently estimated that no less than 60-200 million tons of soil dust have been blown out of the Sahara and surrounding areas over the Atlantic Ocean each summer during the early 1970s. This enormous transport of soil dust seems to coincide with the years of drought and famine in the Sahel of West Africa.
Which processes are responsible for this transport of dust and what does it mean in terms of the loss of productive soil by wind erosion in Africa, of the pollution of the air and possible impact of climate, and of the supply of nutrients and soil particles to the ocean and land areas under the dust trajectories?
In order to highlight these questions a Workshop on Saharan dust was arranged in Gothenburg, Sweden, in April 1977, with the participation of scientists of different disciplines, and the outcome of this workshop has been published in the present SCOPE 14 report on Saharan Dust Transport which contains the Review and Recommendations from the workshop together with the sixteen lectures given at the workshop. *(SCOPE Series)*

Moulds, Toxins and Food
by **C. Moreau**, *Laboratoire de Biologie Végétale, Faculté des Sciences, Brest;*
translated and edited by **M.O. Moss**, *Department of Microbiology, University of Surrey.*
Human and animal foodstuffs as well as the raw materials from which they are manufactured are susceptible to spoilage by moulds, many of which produce toxic metabolites. Subsequently these toxins may cause illness and even death in man and his domestic animals.
In this comprehensive account of fungal toxins Claude Moreau adopts a multi-disciplinary approach covering mycological, biochemical, chemical, veterinary and nutritional aspects of the subject. The book has been considerably updated since the publication of the French edition and contains an additional chapter by the translator on recent developments in the study of mycotoxins. It is well illustrated and there is an extensive list of references.

Venoms: Chemistry and Molecular Biology
by **A.T. Tu**, *Colorado State University.*
Analyzes the venom actions of snakes, scorpions, spiders, bees, wasps, hornets, ants, and Gila monsters to better understand their chemistry and pharmacology. Describes the enzyme and protein content of venoms, giving extensive treatment to the molecular basis of venom actions. Discusses the effects of snake venoms on cell membranes and blood coagulation as well as snake neurotoxins and nerve growth factors. Also discusses the effects of cobra venom on the complementary system and organ transplantation.

Advances in Enzymology and Related Areas of Molecular Biology Vol. 47
edited by **A. Meister**, *Cornell University Medical College.*
The series reviews progress made in the various branches of this expanding science and has become essential to all who wish to keep abreast of the literature. *(Advances in Enzymology Series)*
Contents: Oxygen Reduction by the P450 Monoxygenase Systems; Prediction of the Secondary Structure of Proteins from their Amino Acid Sequence; Carbonic Anhydrase: Structure, Catalytic Versatility, and Inhibition; Hormonal Modulation of Specific Messenger RNA Species in Normal and Neoplastic Rat Liver; Transport of Folate Compounds in Bacterial and Mammalian Cells; Terminal Deoxynucleotidyl Transferase: Biological Studies; The Amino Acid Code; Indexes.

Primate Ecology: Problem-Oriented Field Studies
edited by **R.W. Sussman**, *Washington University.*
Presents twenty-eight articles, representing some of the earlier attempts at problem-oriented field research, on this recent dimension of primate studies. It explores a number of hypotheses concerning relationships between ecological adaptations, morphology, and social studies. The investigations concentrate on a single species in two or more geographical areas with different habitat types, or on a number of species living in the same area. Prosimians, New World monkeys, Old World monkeys, and apes are all covered and the section introductions provide historical, methodological, and background perspectives.

Soviet Scientific Reviews

a new series of authoritative annual reviews of Soviet science containing the most significant developments in physics, chemistry, astronomy, mathematical physics and biology

Edited by **V. I Goldanskii** (Institute of Chemical Physics, Moscow), **R. Z. Sagdeev** (Institute for Cosmic Studies, Moscow), **G. Friedlander** (Brookhaven National Laboratory) and **M. Lévy** (Université Pierre et Marie Curie, Paris)

This new series is published in English, under the auspices of the Academy of Sciences of the U.S.S.R., and aims at making accounts of recent scientific advances in the U.S.S.R. more readily and rapidly accessible to other scientists. Each article in these annual volumes is written by a Soviet expert in the field concerned. Most articles were written originally in Russian, then translated into English, with the aim being speedy publication. Hence most of the articles appear in print for the first time in these volumes, in any language.

SECTION A: PHYSICS REVIEWS
Volume 1 (1979) edited by **I. M. Khalatnikov** Director, L. D. Landau Institute of Theoretical Physics, Academy of Sciences of the U.S.S.R., Moscow

Contents: Foreword (***I. M. Khalatnikov***), The Inverse Scattering Problem and Instanton Construction by Algebraic Geometry (***A. A. Belavin***); Superfluid He^3 Hydrodynamics and Inhomogeneous States (***G. E. Volovik***); Nonequilibrium Phenomena in Superconductors (***B. I. Ivlev***), Soliton Theory (***V. E. Zakharov and S. V. Manakov***), Condensation of Excitons and Electron-Hole Liquids in Semiconductors (***Ya.B. Pokrovskii and V. B. Timofeev***); Radiofrequency and Optical Investigation of Spin Waves in Antiferromagnets (***A. S. Borovik-Romanov, V. G. Zhotikov, I. M. Kreines, L. A. Prozorova and A. I. Smirnov***).

Spring 1979 approx. 400 pages
$60.00/125 Dfl (tent.)
ISBN: 0 906346 06 1

Sections scheduled for publication in 1979 or 1980:

A. PHYSICS REVIEWS
Volume 1 (1979)–Volume 2 (1980) edited by I. M. Khalatnikov

B. CHEMISTRY REVIEWS
Volume 1 (1979)–Volume 2 (1980) edited by M. E. Vol'pin

C. MATHEMATICAL PHYSICS REVIEWS, Volume 1 (1980) edited by S. P. Novikov

D. BIOLOGY REVIEWS, Volume 1 (1980) edited by V. P. Skulachev

E. ASTRONOMY REVIEWS, Volume 1 (1980) edited by R. Syunyaev

ACCELERATORS AND STORAGE RINGS

A series edited by

John P. Blewett and Francis T. Cole

Volume 1: THE MICROTRON

by **S. P. Kapitza and V. N. Melekhin**

Translated from the Russian by
I. N. Sviatoslavsky

English edition edited by **E. M. Rowe**

Contents in brief: The Principle of Operation of the Microtron and Types of Microtrons; Phase Motion in the Microtron; Particle Injection Calculations; Particle Focusing; Construction of a Microtron; Physical Characteristics of the Microtron; Experimental Study of the Microtron; Continuous Wave Microtron; Engineering Calculations; and Motion Characteristics as Expressed by a Second Order Matrix

December 1978 222 pages
$22.00/45 Dfl ISBN: 0 906346 01 0

Volume 2: COLLECTIVE METHODS OF ACCELERATION

Edited by **Martin Reiser and Norman Rostoker**

Based on a conference held in Laguna Beach in 1978 which was dedicated to the late Gersh Budker, this book reports on ERA (Electron Ring Accelerators), IFA (Ionization Front Accelerator), magnetically insulated ion idodes and Luce diodes, ARA (Auto Resonant Accelerator), CFIA (Collective Focusing Ion Accelerator) and other new ideas in this area.

Spring 1979 approx. 678 pages
$43.00/89 Dfl (tent.)
ISBN: 0 906346 05 3

SURVEYS IN HIGH ENERGY PHYSICS
An International Journal

Editor-in-Chief: **John M. Charap**, Queen Mary College, University of London
Associate Editors **K. Igi** (Tokyo), **M. Lévy** (Paris), **R. F. Peierls** (Brookhaven), **A. Polyakov** (Moscow), and **A. Salam** (London)

Quarterly publication scheduled for 1979 ISSN: 0142-2413

Subscription rate: $47.50/90 Dfl (per volume of 4 issues, including postage)

THE UNIFICATION OF ELEMENTARY FORCES AND GAUGE THEORIES

Edited by **David B. Cline and Frederick E. Mills**

Proceedings of the Ben Lee Memorial International Conference on Parity Nonconservation, Weak Neutral Currents and Gauge Theories, Fermi National Accelerator Laboratory

Contributors C. N. Yang, A. K. Mann, A. Rousset, D. Haidt, H. Faissner, F. Reines, G. Feinberg, P. G. H. Sandars, E. D. Cummins, M. A. Bouchiat, L. Pottier, E. G. Adelberger, R. Wilson, C. A. Barnes, M. M. Lowry, J. M. Davidson, R. E. Marrs, F. B. Morinigo, H. E. Swanson, D. Tadić, D. E. Nagle, M. L. Perl, L. M. Lederman, D. D. Reeder, E. Radermacher, V. Barger, D. N. Schramm, G. Steigman, M. J. Perry, J. A. Wheeler, W. A. Fowler, M. Goldhaber, C. S. Wu, H. D. Politzer, F. Wilczek, S. L. Glashow, K. C. Pati, J. D. Bjorken and S. Weinberg

January 1979 792 pages
$39.50/75 Dfl ISBN: 0 906346 00 2

PERSPECTIVES OF FUNDAMENTAL PHYSICS

Edited by **Carlo Schaerf**

Proceedings of the conference held at the University of Rome dedicated to Edoardo Amaldi

Contents: **H. Feshbach**: Nuclear Structure; **N. Cabibbo**: Hadron Physics; **G. Salvini**: Colliding Bean Physics; **L. Maiani**: Lepton Physics; **E. Fiorini**: Weak Interactions. Experiments; **B. Pontecorvo**: Neutrini; **R. Gatto**: Gauge Theories and Supergravity; **G. Pizzella**: Experimental Gravitation; **B. Rossi**: X-Ray Sources in Our Galaxy; **E. Segrè**: The Early Days of Nuclear Physics. **E. Amaldi**: The Years of Reconstruction, **L. Van Hove**: Research Trends and **J. B. Adams**: Large Projects.

June 1979 approx. 300 pages

Cooperative equilibria

Cooperative Equilibria in Physical Biochemistry. By D. Poland. Pp. 344. (Clarendon/Oxford University Press: Oxford, 1978.) £14.

COOPERATIVITY is an important phenomenon in molecular biology. It gives rise to sigmoidal binding curves, to allosterism, to steep conformational transitions, and plays a major role in assembly processes Quantitative treatments were developed for many simple systems and a general understanding was obtained for more complex ones. So far, the only summaries available were contained in several review articles and in a rather specialised book by Poland and Scheraga (*Theory of Helix Coil Transition in Biopolymers*, Academic, 1970)

The present book takes a more general approach. It starts from basic principles, gives a simplified presentation of the equilibrium theory and treats some specific systems as examples for its application. The book originated from a series of courses presented by the author to students at Johns Hopkins University at various levels of their curriculum It has the nature of a lecture script, is well written and reflects considerable teaching experience. The first chapter on simple multiple equilibria is rather elementary. In a long second chapter some concepts of statistical mechanics are repeated and some basic physical principles of intermolecular forces are presented. Three more specific and more demanding chapters are on transitions in linear biopolymers composed of single and multiple chains and on cooperative binding of ligands to linear macromolecules and to a two-dimensional lattice. A last chapter deals with the complications which are introduced when macromolecules are not composed of identical, repeating units but have a more complex sequence.

The main advantage of the book is that it may serve as a well written text for course work or for self-study. It lacks, however, a treatment of cooperativity in self assembly, a topic which is rather important and straightforward for linear systems like actin filaments or bacterial flagella. Two- or three-dimensional problems like the folding of globular proteins or transitions in membranes are not treated in any detail. Most importantly, I feel that a course on cooperative phenomena will be incomplete if the important kinetic features of cooperative systems are left out completely. My own teaching experience shows that equilibria and kinetics can be presented together with considerable advantage for a deeper understanding.

The author did not intend to present a systematic coverage of the research in the field of cooperative systems. The usefulness of the book as a review and as a source of references is therefore limited. References to the literature are few in number and incomplete. A rather severe disadvantage is the lack of a subject index. It has to be emphasised, however, that a short monograph like this can never satisfy all wishes and that the book will certainly be welcomed by many students and research workers who wish to be introduced into the field of cooperative equilibria.

Jürgen Engel

Jürgen Engel is Professor of Biophysical Chemistry at the Biozentrum of the University of Basel, Switzerland.

Moorlands and montane grasslands

Production Ecology of British Moors and Montane Grasslands. Edited by O. W. Heal, D F. Perkins and W. M. Brown. Pp. 426. (Springer: Berlin, Heidelberg and New York, 1978.) DM108; $54.

THIS book comprises a series of research reports from the British part of the International Biological Programme (IBP) studies, mainly from Moor House in the northern Pennines and the sheep-grazed montane grasslands of Snowdonia. The overall emphasis is upon the development of ecosystem models for the two habitats based upon a variety of experimental studies of the component parts, together with mathematical models and simulations of certain critical processes, such as production, decomposition and peat accretion.

Much of the data from the Moor House IBP study has been published elsewhere, though it is useful to have much scattered data collated and condensed here The field studies of Smith and Forrest and the controlled environment work of Grace and Marks on the primary productivity of the blanket mire ecosystem have provided an interesting set of data from a generally neglected habitat. It is particularly useful to have in the same volume some comparable data from the southern English heaths (Chapman and Webb) and from the Cairngorm dwarf heath communities (Summers). Mean production values for the Moor House *Calluna/Eriophorum* blanket mire sites are about 250 gm^{-2} yr^{-1}, those from Dorset heaths about 320 gm^{-2} yr^{-1}, and from the Cairngorms come figures which vary considerably with such factors as soil fertility and degree of exposure, from 75–300 gm^{-2} yr^{-1}. Given the generally small sample areas studied, these figures are in very satisfactory agreement.

One advantage of publishing a collection of site orientated papers is the opportunity of putting together work which would otherwise be published in widely scattered disciplinary journals. So it is valuable to have the Moor House work on fauna and microbes in the same volume as the primary productivity work. A paper which will prove of particular value to peatland ecologists in general is that by Martin and Holding on the factors influencing microbial activity in blanket peat. Microbial activity was stimulated by adding an organic carbon source or by adding nitrogen, indicating nutrient limitations. The physical structure of the peat may restrict access to organic reserves. From the production and decomposition data, Jones and Gore construct a simulation model and Clymo develops a model of bog growth.

The Welsh grassland work is similar to that at Moor Mouse in that it deals with a montane habitat, but it differs in many other respects, such as the density of sheep. On Pennine blanket mire this was only 0.13 per hectare, whereas on the *Agrostis/Festuca* grasslands in Snowdonia it attained 9 per hectare. So the studies of sheep populations (Dale and Hughes) and their productivity (Brasher and Perkins) form important constituents of the Snowdonian work. The final summary of energy and nutrient flow patterns by Perkins is particularly useful and could have been emulated with profit by the Moor House team. From the diagram produced one can discern at a glance some fascinating aspects of the sheep-grazed ecosystem, such as the fact that there is more potassium in sheep dung (per unit area) than in sheep, and that earthworm nitrogen exceeds that in sheep whereas sheep have twice the energy content.

The bibliography is extensive and the book will prove an essential reference work to all who conduct research in these montane environments in Britain.

Peter D. Moore

Peter D. Moore is Senior Lecturer in Plant Sciences at King's College, University of London, UK.

Thin film devices

Active and Passive Thin Film Devices. Edited by T. J. Coutts. Pp 858. (Academic. New York, London and San Francisco, 1978.) £60.

If one expects the value of a technical work to keep pace with its cost and size then at a price of £60 at a weight of over 3 lb a purchaser is likely to be disappointed with the work under review. Unfortunately the subject matter is neither sufficiently thorough in its range nor adequately coordinated to constitute a satisfactory reference text on the chosen theme. How, you may ask, is this possible with 858 pages at the editor's disposal: the answer is that the editor has not adopted a policy towards his reader when choosing the subject matter. This is an applied physicist's work not an engineer's, and equal emphasis is given to realised devices as well as promising ones and failures, which might be acceptable if the reader were warned accordingly at the outset.

The book, containing thirteen chapters by specialists, covers thin film preparation, electrical properties of film materials and their uses or potential uses as passive elements and active components. The chapters describing solar cells, optical waveguides and magnetic and superconducting devices are useful reviews, but the references and appended notes indicate that the book was written by 1976. Nearly two years in printing is too long for such a rapidly moving field; consequently molecular beam epitaxy is given a proof reference and solar thermal converters which are in advanced development receive three lines of text.

The development history of thin film systems is littered with failures in deposition techniques and film materials, but such is the speed with which novel devices are invented that the search for new materials and growth processes continues unabated (except perhaps in the UK). Under such circumstances what should an editor include in a book on thin film devices? First, he must decide to whom the collected reviews are directed: the dust-cover suggests physicists, electronic and production engineers and material scientists. This is a broad readership that one cannot expect to have the discrimination of specialists when judging which devices are of practical value and which of historical interest. Thus the editor has given the same emphasis to thin film transistors and threshold switches (although their effective use after a decade is still awaited) as to resistors, capacitors, photoconductors, and so on. Of course one does not want to waste knowledge of physical characteristics arising from an unfulfilled product development but much of this could have been discussed in the chapters devoted to electrical properties of film materials. In view of the importance of silicon technology the most serious weakness perhaps is the omission of a chapter solely devoted to the growth and uses of epitaxial and amorphous silicon and of silicon compound films. Also there is an artificiality in restricting discussion to wholely thin film systems when thin films are so vital a part of most solid-state devices

When discussing the history of the use of thin films in electronics T. J. Coutts states that there would have been no advantage of using thin film resistors in the period of bulky valve circuitry, but the requirements of microminiaturisation made their use essential. This is an incomplete view of what occurred Thin film resistors using NiCr alloys came into use in World War II for waveguide attenuators and were later used for precision resistors The reason why vacuum deposited films were not used in valve circuits was that they broke down when operated at voltages in the 100V region However, development continued in the 1950s on transparent conducting coatings for windows and on the deposition of insulating films and the metallising of capacitor foils (which commenced before the War). Thus, considerable know-how existed on passive devices when the transistor became a production item and a more correct view is the convergence of technologies resulting in the manufacture of hybrid and integrated circuits.

In the chapter on "Preparation Methods for Thin Film Devices" the author has chosen to describe a variety of techniques rather than concentrate on specific kinds favoured for making the devices considered in the other chapters. The emphasis given to metal filaments and boats for evaporation suggests a subject treatment one would have found a decade or more ago and the availability of such refractory materials as B/Ti/N complexes for the high rate evaporation of aluminium is not mentioned Also magnetron sputtering is not described although it has helped to cause a renaissance in the use of sputtering in solid-state technology and most of the advances leading to cylindrical and planar magnetrons were made by 1974, that is, before the book was written.

The book is not an embracing text, and is inadequate in its treatment of deposition processes and lacks balance in its choice of devices. However, as stated above, there are several specialist chapters which are valuable reviews

L. Holland

L Holland is Head of the Unit for Plasma Materials Processing at the University of Sussex, UK.

Reflection seismology

Reflection Seismology: A Tool for Energy Resource Exploration. By K. H. Waters Pp 377. (Wiley: New York and Chichester, UK, 1978.) £19.75.

By far the most successful method of determining the structure of the upper few kilometres of the Earths' crust has been and continues to be the art and science of reflection seismology. This book provides an essentially complete survey of the subject from the basic physical principles to the multitude of data generation and analysis tools currently used by the oil exploration industry. The volume is perhaps too short on mathematics. However, the physics, including the underlying assumptions of each technique, are generally well presented.

The volume begins with a general description of the pertinent aspects of elastic wave propagation in the upper crust of the Earth Following chapters cover seismic energy generation techniques, data-gathering methods, stacking and filtering techniques, and the reduction of processed data to the geometry and physical properties of the rock formations below. Introductions to such recent and current topics as homomorphic deconvolution, adaptive filtering, maximum entropy spectral analysis, integral and differential wave equation migration, shear waves, high frequency methods and three-dimensional data collection and analysis are included.

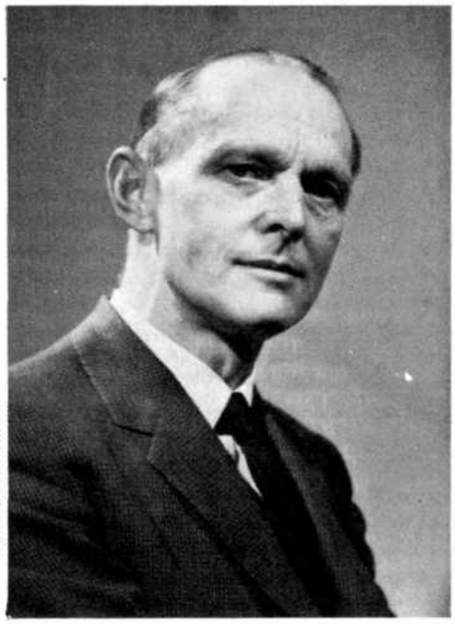
The professional exploration seismologist will find that they know a great deal more about many of the subjects covered in this book, and students whose desire is a thorough knowledge of any given topic will require a more detailed and explanatory presentation However, the volume is well referenced (up to about 1973). The book is appropriate and recommended for those who want a basic technical introduction to exploration seismology from beginning to end.

Tom Landers

Tom Landers is a staff member at the Applied Seismology Group of Lincoln Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts

obituary

Norman Feather, 1904-1978



John Dewar Studios

Professor Norman Feather, FRS, died on 14 August 1978 at the age of 73. His death has removed one of the last of that brilliant group of young men who gathered round Rutherford at the Cavendish Laboratory, and later guided the postwar expansion and flowering of academic physics in Britain.

Feather was born at Crimsworth, in the West Riding, the son of two school teachers. At Bridlington School he came under the influence of an inspiring science master, and this led him to decide to study physics at Trinity College, Cambridge. In 1926 Feather was awarded his BA degree at Cambridge, and the BSc degree of the University of London.

For the next three years he worked as a research student, under Chadwick, on the development of cloud-chamber techniques and their application to a study of the rare long-range α-particles from Radium-C. In 1929 he was awarded a Fellowship of Trinity College. The award was for a period of four years, and he spent the first of these years at Johns Hopkins University in Baltimore, at the behest of R. W. Wood. He returned to Trinity College in 1930 and submitted—successfully—his PhD thesis.

In his luggage Feather had brought back with him 300 'dead' radon bulbs, from the Kelly Hospital in Baltimore, containing in all about 100 millicuries of polonium. It was with this polonium that Chadwick, Dee, and Feather established in 1932 the production of neutrons when beryllium was bombarded by α-particles, and in particular Feather, using his automatic cloud-chamber, produced the first clear evidence for the transmutation of nuclei by neutrons.

Feather's next cloud-chamber experiment was a study, jointly with Bretscher, of the photo-disintegration of the deuteron. The value they obtained for the deuteron binding energy was challenged by Bethe, on the basis of his theoretical studies of the rate of energy loss of charged particles in matter. The Bretscher–Feather value was subsequently vindicated by more refined experiments elsewhere. Feather had never doubted that it would be: his calibration data had been accumulated during years of painstaking observation and comparison.

Feather frequently pointed out to his colleagues and juniors that he had never been exposed to the higher reaches of mathematics nor to any quantum theory—'just a little applied mathematics'. And he would go on to maintain, with a glint in his eye, that there were still things to do in nuclear physics where insight and intuition were the best guides. When it was necessary his mathematics tended to rise to the occasion, as in his early studies of the statistics of the prompt- and delayed-coincidence techniques which he used in β-ray spectrometry and the investigation of nuclear isomerism, in the late 1930s. But when his insight and intuition were involved they were backed up by a vast and detailed knowledge of nuclear systematics, which found expression in his monograph on *Nuclear Stability Rules* (1952) and in his later writings on nuclear fission.

When Chadwick went to the Chair of Physics in Liverpool in 1935 Feather went with him, but remained there for only one year, during which he wrote his first undergraduate textbook, *An Introduction to Nuclear Physics*. In 1936 he returned to a lectureship in Cambridge, in charge of his own research group. A year later Rutherford died, and subsequently Feather found himself with more responsibility for the nuclear work in the Cavendish Laboratory. During the war years he carried a very heavy administrative load, both in the teaching programme and in the war-time work on nuclear fission.

In 1945 Feather was elected to the Fellowship of the Royal Society, and appointed to the Chair of Natural Philosophy in Edinburgh. He occupied this chair, as Head of Department, for 30 years. His first task in Edinburgh was to build up a department in which the techniques which had transformed nuclear experimentation during the war years could be developed and exploited. He was joined by a number of talented young men, and work was soon under way in the β and γ-ray spectrometry of (mainly) naturally radioactive species, and in radiation chemistry and fast-neutron physics. Feather was not a man to stifle or constrain those of his staff who wanted to work in other fields, and projects on cosmic rays, meteorology, fluid dynamics and metal physics got under way too. The undergraduate curriculum was drastically overhauled, and by his own example Feather transmitted his view of the interdependence of undergraduate teaching, postgraduate training, and research.

With his Department running smoothly, Feather for a time concentrated his energies on writing and produced a series of texts aimed at undergraduates. Although his rather mannered style was not altogether congenial to the undergraduates of the 1950s and 1960s, the combination in these books of care for language, extensive knowledge, and a scholarly and disciplined approach, was an affirmation of values which the author felt impelled to exhibit to his students.

In the 1960s Feather's attention turned again to the fission process, and a series of papers followed which dealt with the process of ternary fission, and especially the α-particles emitted in fission. His lifelong interest in the various aspects of α-emission continued into his retirement. His penultimate paper, published in 1978, discussed the two solutions that have been proposed to the problem of the polonium haloes in mica. Something of the essence of the man flashes out in a characteristic sentence: 'Because these two suggestions appear to exhaust the logical possibilities of explanation, it is tempting to admit that one of them must be basically correct, but whoever would make this admission must be fortified by credulity of a high order.'

Feather's keen and incisive mind and his remarkable detachment made him a distinguished academic administrator.

His services to such bodies as the Scottish Universities Entrance Board, the Home Defence Scientific Organization, and the Royal Society of Edinburgh (which he served for many years, as Councillor, as General Secretary, and then as President) were generously given and widely appreciated. The University of Edinburgh acknowledged his notable services to the University community by the award of the Honorary Degree of Doctor of Laws, just a few weeks after he retired.

R. M. Sillitto

Herbert Dingle

THE well-known spectroscopist, astrophysicist, philosopher of science and critic of relativity, Herbert Dingle, died in Hull on 4 September 1978, not long after his 88th birthday.

Although of Cornish descent, Dingle was born in London, close to his beloved Surrey county cricket ground, the Oval, on 2 August, 1890. He spent most of his boyhood and youth in Plymouth, where his mother had returned on the death of her husband. After leaving school at the age of fourteen, Dingle worked for over ten years as a clerk by day and studied, as best he could, by night. In 1915 he won a Royal Scholarship for Physics at Imperial College. He graduated in 1918, having already been appointed to the staff of his department. The same year he married Alice Westacott. She predeceased him by over thirty years. He remained devoted to her memory. They had one son who became an industrial chemist, but he too died before his father.

More than three-quarters of Dingle's academic career was spent at Imperial College, where he was eventually promoted to a chair in natural philosophy in 1937. Originally, he specialised in spectroscopy under Alfred Fowler, the successor of Norman Lockyer. On Fowler's retirement in 1935, he became head of the spectroscopy section. Under Fowler, Imperial College had been in the forefront of physics, in the great days of line spectroscopy following the introduction of the Bohr atom. It was no fault of Dingle's that his time as head of the spectroscopy section coincided with a world-wide lull in the subject, prior to its revival, under the impact of nuclear physics, in the nineteen-fifties. Nevertheless, Dingle did useful work in spectrochemical analysis and pioneer research on the spectra of fluorine II and III. He wrote much on the laboratory and astronomical applications of spectroscopy.

His book *Modern Astrophysics*, published in 1924, was one of the first on that subject. He was also part author of *The Splendour of the Heavens*, published in 1923, and *The Life and Work of Sir Norman Lockyer*, published in 1929.

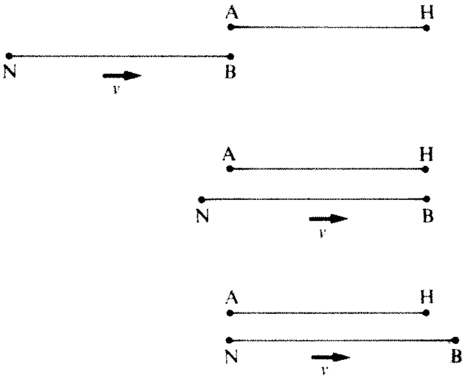
From the early nineteen-twenties Dingle was actively concerned with the philosophical as well as with the practical aspects of physics. He developed a highly professional interest in the philosophy of science and as a writer in that field he became very well known, particularly in the United States, which he visited for two lengthy periods in the thirties, the second time as Lowell Lecturer at Harvard. During the prolonged absence of Sir George Thomson from Imperial College during World War II Dingle was effectively in charge of the physics department.

Dingle's philosophy of science, as expounded in his books *Science and Human Experience* (1931) and *Through Science to Philosophy* (1937), the latter based on his Lowell Lectures, was in the new unfashionable tradition of British empiricism. He believed that the essential basis of science was the rational correlation of elementary experiences which can be made objective. This led him to adopt a philosophy which had much in common with that of Ernst Mach.

In 1946 Dingle was appointed Professor and Head of the Department of History and Philosophy of Science at University College, London, a post that he held until his retirement in 1955. Although no longer active in spectroscopy and astrophysics, he was elected President of the Royal Astronomical Society from 1951 to 1953. He was also President of Commission 41 (History of Astronomy) of the International Astronomical Union for some years and was a Vice-President of the International Union for the History of Science from 1953 to 1956. He founded in 1948 the Philosophy of Science Group of the British Society for the History of Science (which later became the British Society for the Philosophy of Science). Two years later, with the support of the late Dr H. P. Morrison of the publishing firm Nelson, he founded *The British Journal for the Philosophy of Science*. From 1955 to 1957 he was President of the British Society for the History of Science.

In the latter year he began his famous campaign against the special theory of relativity which dominated the last twenty years of his life. He had originally been sympathetic to the theory, particularly because of the ostensibly 'operational' philosophy that had guided Einstein in its creation, and in 1940 he published a Methuen monograph on it. His doubts originated when, while reading Sir George Thomson's *The Foreseeable Future*, he came across a passage relating to the 'clock paradox'. As a result, he engaged in a controversy in the correspondence columns of *Nature* with Professor W. H. McCrea, FRS, which led to a tremendous resurgence of interest in the 'paradox' and a spate of publications on it.

Later Dingle attacked the entire concept of relativistic time. His basic objection was that, according to the theory, two similar clocks, A and B, in uniform relative motion V work at different rates, but since the relation of each to the other is symmetrical it follows that, if A works faster then B, B must work faster than A. He argued that this was a contradiction and so the theory must be false. The point at issue was a subtle one and concerned the way in which Dingle used a particular concept which he called 'rate of clock'. He exemplified this by taking A and B to be together at epoch zero according to each and introducing two other clocks H and N at rest relative to A and B, respectively, but not spatially coincident with them. He compared the times t_1, t'_1 assigned to the epoch of B's momentary coincidence with H by the observers using the clocks A, B respectively, and the corresponding times t_2, t'_2 assigned to the epoch of A's momentary coincidence with N. He then argued that, since special relativity led to the formulae, $t_1=\beta t'_1$, $t_2'=\beta t_2$, where β is the reciprocal of $\sqrt{(1-V^2/c^2)}$, a contradiction results. This is because in the former case the ratio of the 'rates' of clocks A and B is given by t_1/t'_1 and in the latter case by t_2/t'_2, and hence this ratio has two incompatible values.



The difficulty can be resolved by rejecting Dingle's assumption that ratios such as t_1/t'_1 determine invariant relative 'rates' of clocks A and B. His implicit requirement that the epochs assigned to *any* event by A and B, respectively, should always be in the same ratio would imply that by a new choice of time unit for one of these clocks it could be arranged that the times assigned to any given event by A and B would be the same. Dingle's requirement is therefore equivalent to adopting the Newtonian concept of universal time, and this is incompatible with special relativity.

Dingle believed that his question concerning clock-rates was not answered but evaded by his critics. In his struggle with what he came to regard as the 'relativistic establishment', described in his book *Science at the Crossroads* (1972), he was often treated in a way that convinced him that truth was being sacrificed to dogma. His attitude towards relativistic physics was not, however, purely negative, for he adopted, and spent much time in developing, the alternative 'ballistic' theory of light-transmission due to W. Ritz.

Despite his criticism of special relativity, Dingle never lost his respect for Einstein's genius, just as he no less admired his fellow quaker Eddington despite submitting the latter's philosophy of physics to devastating criticism in his brilliant Eddington Memorial Lecture on *The sources of Eddington's philosophy* (1954).

No obituary notice of Dingle should fail to mention the beautiful literary style that graced all he wrote. He had a deep knowledge and appreciation of English literature, particularly poetry. Two of his books were on *Science and literary criticism* (1949) and *The mind of Emily Brontë* (1974). His friends will long remember his lively conversation spiced with a rapier-like wit and numerous anecdotes, and his many acts of kindness, not least to those refugees from Europe whom he and his wife so generously assisted in the nineteen-thirties.

G. J. Whitrow

M.H.L. Pirenne

Maurice Henri Léonard Pirenne, well known for his work in the physiology of vision, died in Oxford on 11 October 1978.

Maurice Pirenne was born in Verviers, Belgium in 1912. He graduated DrSc at Liège, and spent the next year doing research in molecular physics with Professor Debye. The following three years were spent at Columbia University, New York, with Selig Hecht studying the biophysics of vision, and it was probably this period, more than any other, that determined his future interests.

In 1942, a classical paper by Hecht, Shlaer and Pirenne demonstrated that the uncertainty of seeing near the visual threshold, usually attributed to biological variation, was in fact largely accounted for by purely physical variations in the small number of light quanta absorbed by the visual photopigment. Much of Pirenne's later work was concerned with the visual threshold and its relationship to visual acuity, ranging in scope from the practical problem of screening servicemen for night blindness, to neurophysiological studies of the thresholds of 'on' and 'off' units and their interaction.

He returned to England in 1941 and worked in Cambridge, London and Aberdeen before joining the University Laboratory of Physiology, Oxford, in 1955. He became a fellow of Wolfson College, and worked in Oxford until his retirement. As a teacher, he will be remembered particularly for his demonstrations and class work. The experiments that brought the subject so vividly to life were based upon long hours of preparation and adjustment.

Maurice Pirenne was the son of an artist, and while he was still at school his father encouraged him to read the work of Brücke and Helmholtz on vision and art. His interest in drawing and painting lasted all his life, and in recent years he had returned to the study of the relationship between visual physiology and the perception of pictures. *Optics, Painting and Photography* (1970) is concerned mainly with perspective, and how far a painting in perspective can really look convincing to an observer who, instead of viewing it with one eye placed in the ideal position, uses both eyes and moves to different positions. His last publication, in 1975, was on Vision and Art.

All Pirenne's scientific work was characterised by acute commonsense and painstaking accuracy. The same qualities appear in his published work. *Vision and the Eye*, which first appeared in 1948 remains the clearest and most readable introduction to the subject. He was internationally recognised as an authority on visual physiology, and in 1972 received an ScD at Cambridge and was appointed a Foreign Member of the Royal Belgian Academy of Sciences.

F. H. C. Marriott

B. B. Roberts

Brian Birley Roberts, authority on polar problems and ornithologist, died in Cambridge on 9 October 1978 at the age of 65. For thirty years Head of the Polar Regions Section, Foreign and Commonwealth Office, he was also a Research Fellow at the Scott Polar Research Institute, Cambridge and a Fellow of Churchill College.

His interests in the polar regions started when he was still a schoolboy and he became probably the foremost specialist in the world. As an undergraduate at Emmanuel College, Cambridge, he led expeditions to Iceland and East Greenland in 1932 and 1933 and later joined the British Graham-land Expedition (1934–1937). As an ornithologist, he will be particularly remembered for his paper on Wilson's petrel published in 1940, which has stood the test of time as a good and careful study. It dealt with breeding behaviour, growth and reproductive success; the remarkably long annual migration was illustrated by monthly distribution maps and supported by ringing returns, which proved that individuals return each year to the same mate and burrow in the Antarctic.

In 1940 he took a Cambridge PhD and was awarded the Polar Medal and the Bruce Memorial Prize of the Royal Society of Edinburgh. He received the Back Award of the Royal Geographical Society in 1948. During the war years he served in Naval Intelligence and advised the War Office on cold climate equipment. He revisited the Antarctic in 1950–51, 1960–61, 1964, 1972 and finally in 1976, shortly after his retirement.

Brian Roberts played a formative role in discussions leading to the Antarctic Treaty (1959) which ensured the continuance of the freedom of scientific investigation and the free exchange of results which marked the International Geophysical Year 1957–1958. He did much to promote the Agreed Measures for the Conservation of Antarctic Flora and Fauna (1964) and the Convention for the Conservation of Antarctic Seals (1972). While he asserted that he had had to *eat* more seals than any others present, he was dedicated to conservation and also regarded that convention as the forerunner of a broader convention dealing with other Antarctic marine living resources, especially krill, now being negotiated. Although often the only scientist in a group of diplomats and lawyers, it was to Brian Roberts that they frequently turned for help in resolving a diplomatic impasse.

He played an active role in the formation of the British Antarctic Survey and he had an enduring influence on the development of the library of the Scott Polar Research Institute and the establishment of what developed into the International Glaciological Society. He was a leading expert on Antarctic history, terminology and place names.

He was made CMG in 1969 and in 1976 was awarded the Founder's Medal of the Royal Geographical Society. He was president of the Antarctic Club in 1963 and of the Arctic Club in 1973.

Many senior polar scientists benefited, as young research workers and later, from the stimulation of his presence, his phenomenal range of detailed knowledge and constructive criticism. His beaming smile, kindness, wit, scholarship, experience and great capacity for work will be long remembered by his many friends, who will find it difficult to believe he is no longer there.

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US $1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

nature Ocean sciences supplement

Reprints of this 40-page supplement covering many aspects of oceanography and the politics of ocean science, which appeared in the issue of 30th June, 1977, are now available at the following prices (including postage):

Single copy:	UK	50p
	Rest of World	US $1.00
	Rest of World (Air)	US $1.50
10 or more copies:	UK	35p each

Safety and Laboratory Practice

John G. Ellis &
Norman J. Riches

Macmillan Technician Series

* A unique and comprehensive text in which information is given on Safety, Law and Laboratory Organisation.

* Ties in directly with courses leading to the Technician Certificate of the TEC in Sector C.

* Large format, many illustrations.

An invaluable text for the TEC student and a most useful work of reference for all those engaged in laboratory work.

Contents

1. Laboratory first-aid
2. Electrical Safety
3. Fire Safety
4. Technicians and the Law
5. Safety in Chemistry Laboratories
6. Safety in Physics Laboratories
7. Safety in Biology Laboratories
8. Scientific Measurements and Reporting
9. Laboratory Standards

Appendices

£3.95; 112pp; 203×234mm;
0 333 23312 3

For further details contact Rosemary David, The Macmillan Press Ltd., 4 Little Essex St., London WC2R 3LF.

M MACMILLAN PRESS

...Run...

It's all very well being poker-faced when the question of safety is raised . . . but when disaster looms and the only advice is "Run"! you must admit that things are a little out of hand. Take the gamble out of work in the laboratory . . . make sure you always have a full house . . . keep yourself informed about safety regulations and requirements.

BDH has a wide range of wall charts and safety aids for the laboratory, ask for details . . .

BDH BDH Chemicals Ltd Poole BH12 4NN

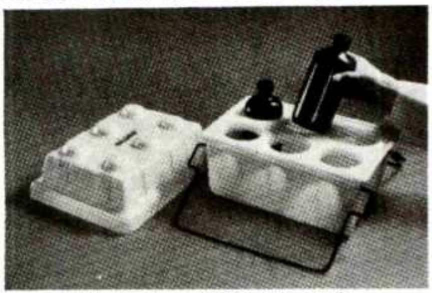
Circle No. 10 on Reader Enquiry Card.

what's new—lab design and safety

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover.
A feature on the 1979 FASEB Exhibition will appear in the 29 March issue.

Dohm. Dangerous liquids can be transferred safely and quickly without waste with the polyethylene syphons produced by Dohm London Ltd. The AA model has a 3/4 pint bellows capacity, can provide a flow of up to 1½ gallons per min and is 91 inches in overall length. The AAG is of 3 pint capacity, flow rate 3 gallons per min and overall length 128 inches. The Dohm safety inspection lamp is suitable for use in confined spaces: the light is evenly diffused by an anti-glaze reflector to prevent eye strain. For situations in which 110 or 240 V power supplies are a safety hazard Dohm produce the DOHMplug range. These compact transformer/rectifier units give a 40 W output at 6, 12, 25, 50 and 110 V.

Circle No. 60 on Reader Enquiry Card.



The Nalgene 6505 bottle carrier

Sintacel. Metriscope from Sintacel is a comprehensive range of equipment capable of fulfillng the servicing and furnishing requirements of educational and laboratory accommodation. The range provides non-fixed furniture with overhead service booms and drainage equipment. All furniture is either movable or mobile and the working surfaces, with their flexible service/drainage connections, can be quickly re-arranged. The overhead service booms may provide such services as gas/electricity/water/vacuum/lighting. Drainage is normally dealt with by means of a regularly spaced grid of floor outlet points, but if so required, wall or overhead drainage may be provided.

Circle No. 59 on Reader Enquiry Card.

Nalgene. An extensive range of safety equipment suitable for laboratory use is available from the Nalge Division of Sybron Corporation. The Nalgene emergency eyewash station weighs only 11 pounds and is based on a reservoir of 2.5 litre volume and once the release bar is depressed a continuous stream of water is produced: both hands are left free to keep the eye open to receive the stream, which will last from four to six minutes. The 6355 range of Nalgene safety shields are formed from 0.188-inch Lexan and can resist impact from explosions, flash fires, flying particles or splashing liquids. These shields are mounted on a heavy epoxy-coated steel base to ensure stability. Nalgene 6355 face shields are made with 0.06-inch polycarbonate. The transparent shields cover the front, sides, and top of the head, plus the front of the neck. For the transportation of hazardous substances around the laboratory Nalge provide two types of carrier. The 6501 safety bottle carrier is made of polyethylene and holds a 5-pint or 1-gallon glass bottle securely with provision for a snap-on cover. The 6505 bottle carrier holds up to six 1-pint glass bottles in separate compartments. Large volumes of liquids can be safely stored in Nalgene carbouys. Also available from Nalgene are safety wash bottles. These are intended for use with inflammable or toxic substances and are made of red polypropylene.

Circle No. 58 on Reader Enquiry Card.

The emergency eyewash station from Nalge

Data Acquisition. The DA 1500 mercury vapour detector is manufactured by Data Acquisition Ltd, in association with ICI Ltd., Mond Divi- principles based on the absorption of sion. The instrument operates on ultraviolet light by mercury at a wavelength of 2,537 Å. The basic systems comprises a sample cell fitted with a UV light source and measuring and reference detectors. The detector output signals are fed to a solid state amplifier whose linear output, drives a four digit display. An output is also available to drive a recorder via front panel terminals. The instrument is portable and measures approximately 160 × 160 × 700 mm and weighs about 12 kg.

Circle No. 57 on Reader Enquiry Card.

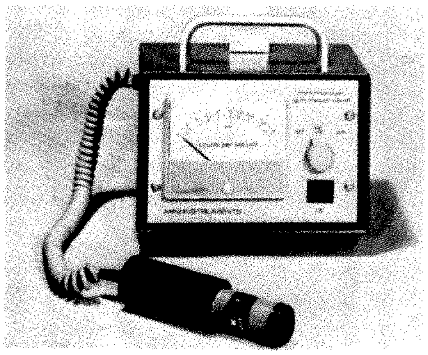
The DA 1500 Hg vapour detector

Berthold. The advances made by Berthold, in large area contamination probes, have been applied to the new whole body contamination monitor. This allows the simultaneous monitoring of the face, clothing (at the front of the body to the feet), soles of feet and hands. All the detectors are the new xenon filled type having very high sensitivity for iodine-125 and carbon-14 and without the requirement for a continuous supply of gas to the detectors. The device routinely stores background information when not in use and automatically subtracts this at the appropriate rate during measurement. The system permits the measurement of most transuranium isotopes through their emitted K-radiation thus allowing them to be monitored despite the unavoidable distance between the detector and the body to be checked. For institutions where exposure to high activity radiation is possible, the monitoring of workers normally needs to be recorded and stored. The system can be supplied and delivered with an identity card reader with data output to either a Teletype or on-line computer.

Circle No. 56 on Reader Enquiry Card.

Research Products International. The RPI brochure 'Contamination and Radiation Monitoring Instruments' details the RPI line of protable geiger-muller tube and sodium iodide crystal instruments. These instruments are used for the detection and monitoring of α, β, γ and X ray radiation in research, hospital, teaching and industrial laboratories. Rugged dependability and minimal maintenance are provided by solid state components mounted on glass reinforced printed circuit boards. Advance circuitry stabilises battery voltage, affording consistent accuracy throughout battery life without need for recalibration.

Circle No. 55 on Reader Enquiry Card.



The RPI model 5-10X contamination monitor

Safety Technology Ltd. A new concept in Zener safety barrier systems for electronic interfaces has been announced by Safety Technology Limited of Feltham, Middlesex. The new system, designated Eurobloc-80, uses specially designed Zener barriers called Euroblocs, which 'snap' into internationally recognised terminal block rails within equipment cabinets. Although electrically identical to existing types of Zener barriers, the new Euroblocs are built into standard terminal blocks, which clip into the DIN rails with a high packing density. The connection and replacement of each Eurobloc can therefore be made very quickly, and arrays will take less space. STL claim that it is possible to obtain up to 3 times the packing density of conventional barriers.

The old type of barrier required specially drilled busbars and a prolonged assembly process involving the tightening of 4 lock-nuts per unit. In contrast, each Eurobloc clips straight onto the standard DIN terminal rail and requires no additional mechanical fixing. Electrical connectors are also easier, as each Eurobloc will accept basic stripped and tinned leads—the old barrier needed special ring tags. A further inherent advantage of the new system is the ability to make all connections at the front face of the module. It is no longer necessary to have either raised busbars or rear access for mounting purposes. Dimensionally the Eurobloc barrier measures 58 × 67 × 18 mm—effectively, half the size of the conventional unit. Initially ten standard types of Eurobloc are being introduced, covering the operating voltages of 4, 10, 15, 22 and 28V, in positive or negative polarity. Double barrier forms may be constructed by simply 'doubling-up' Euroblocs. a.c. voltages are catered for by using a special a.c. adapter. The ten standard Euroblocs can thus be applied in over 60 different variations for which BASEEFA approval has been obtained. Identification is achieved using colour coded labels attached to the Eurobloc.

The use of standard 'building bricks' —the DIN standard terminal block— means that costs are minimised. Wiring is generally neater and cabinet space, which is expensive in environments like oil production platforms, reduced.

The Eurobloc 80 range has been BASEEFA Certified to the New European Certification CENELEC EN.50-020 and UK Certification BS 5501 Part 7. It thus fully complies with the requirements of intrinsically Safe barriers for use in hazardous areas.

Circle No. 54 on Reader Enquiry Card.

Variable Volumetrics. Variable Volumetrics introduce a disposable transfer pipette with ultra lean tube. This polyethylene transfer pipette has a tube so narrow that it will fit into almost any size test tube. It is a one-piece pipette complete with its own bulb, and will eliminate the danger of broken glass, operator contamination from having to change rubber bulbs and cross contamination of samples with contaminated pipettes or rubber bulbs. The pipette delivers 21–24 drops per ml, and has a maximum capacity of 3 ml.

Circle No. 53 on Reader Enquiry Card.

Gallenkamp. A combination of traditional and modern timber-based materials, Gallenkamp System M furniture is robust, hard-wearing and attractive in appearance. The modular units are versatile and freely interchangeable. Most of the units are designed so that they can be packed flat. Modules available incorporate benches with a choice of drawer, cupboard or tray under storage units, sinks, mobile demonstration bench units and a fume cupboard.

Circle No. 52 on Reader Enquiry Card.

Jencons. A mitten style pyroglove has been added to the range of safety gloves marketed by Jencons (Scientific) Ltd. This mitten style is available in wrist or gauntlet length, and consists of a separate thumb sleeve and an area for the four fingers. Normal style Pyrogloves in wrist or gauntlet length are also available and were made to replace the asbestos type gloves previously used by glassworkers when handling their hot glassware direct from the flame or annealing oven, yet possess the tactile qualities of ordinary leather, will absorb moisture and retain water vapour permeability—thus making them comfortable in use.

Circle No. 51 on Reader Enquiry Card.

Becton Dickinson. BBL Biohazard cabinets from Becton Dickinson are officially listed under National Sanitation Foundation Standard 49 and are Class II Type A or Type B containment hoods intended for work involving low to moderate risk agents, such as aetiologic agents CDC Classes 1–3, low to moderate risk oncogenic viruses, recombinant DNA and other uses where National Sanitation Foundation Standard 49 design specifications apply. The cabinets are available in 47- and 70-inch sizes. A vertical laminar air flow incorporates HEPA filters with minimum collection efficiencies of 99.97% for 0.3 μm and larger particles, which minimises cross-contamination within work area by inhibiting particles from moving horizontally. The complete cabinet is at negative pressure to the laboratory atmosphere.

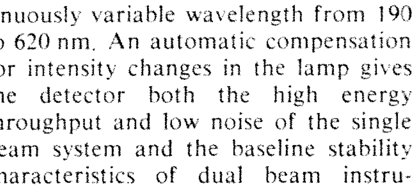
newly on the market

Material for singlet oxygen generation. Chemical Dynamics. Sensitox is a polymer-supported rose bengal used to generate singlet oxygen in aqueous or solvent systems. By binding rose bengal to a porous crosslinked polymer in bead form (200–400 mesh), the separation of the dye from the reaction product is eliminated. The polymer has been designed so that it can be separated from the reaction mixture by simple filtration, thus eliminating the decolorisation step. Sensitox I is for use in low polarity organic solvents whereas Sensitox II is best used in aqueous media.
Circle No. 39 on Reader Enquiry Card.

Temperature gradient incubator. Scientific Industries. The Scientific Industries temperature gradient incubator allows 60 different samples to be incubated simultaneously at 30 different temperatures in a single self-contained precision instrument. The incubator allows aerobic and anaerobic measurements, accommodating a variety of media which may be incubated at the same time or independently. 60 liquid samples can be incubated in glass L-tubes, optically selected to permit nephelometric or colorimetric measurements without sample transfer. There is also a built-in shaker. Aerobic organisms on solid media can be incubated in parallel trays.
Circle No. 40 on Reader Enquiry Card.



Scientific Industries incubator

Variable wavelength absorbance monitor. Isco. The Isco model 1800 chromatographic monitor provides continuously variable wavelength from 190 to 620 nm. An automatic compensation for intensity changes in the lamp gives the detector both the high energy throughput and low noise of the single beam system and the baseline stability characteristics of dual beam instruments. Easily removable flow cells allow the instrument to be used on HPLC systems, as well as in low pressure column chromatography. The instrument may be used in a cold room at 5 °C with no precautions.
Circle No. 41 on Reader Enquiry Card.

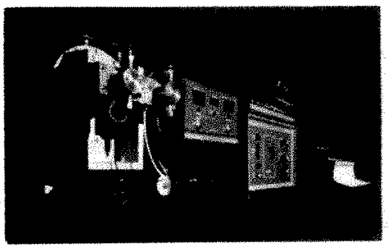
Recorder. Bryans Southern. The Bryans BS 8000 is a multichannel recorder with data processing and storage facilities. The BS 8000 enables one to digitise, record and process up to 8 channels of analogue data. Raw or processed data are plotted in real time on the XY plotter or stored on a flexible disk. Each flexible disk is equivalent to 100 yd of chart paper, yet any sequence of data can be retrieved in graphical form in a few seconds.
Circle No. 42 on Reader Enquiry Card.

Anti-mouse IgD antibody. Sera-Lab announces the availability of a monoclonal antibody against mouse IgD-like antigen. The determinant molecule appears to be a tetramer of 185,000 consisting of two units of 70,000 and two of 22,500 molecular weight. This addition to the range of monoclonal antibodies seems to recognise the Ig-5 locus regardless of H-2 haplotype. The antibody is suitable for use in complement-dependent lysis tests as well as direct reactions using fluorochrome or isotope markers. Because of its high titre, which approaches 10^6, the antibody is an ideal reagent for the study of the function and structure of murine IgD-like molecules. The exact allotype specificity, using the Goding nomenclature, has been defined as Ig5.C3(H6/31).
Circle No. 43 on Reader Enquiry Card.

Wet test meter. International Gas Apparatus. A portable meter capable of accurately measuring small volumes and low flow rates using the traditional wet test meter principle, is now available from International Gas Apparatus. A special feature of the meter is its capability to operate up to 30 p.s.i. working pressure. Measurement of gas volume is better than 0.5% and that of liquid temperature ± 1% of full scale over a temperature range of 0–50 °C.
Circle No. 44 on Reader Enquiry Card.

Small scale protein concentrator. Sartorius. The microcollodion bag from Sartorius enables a 250 times concentration of urine, CSF or aqueous humour to be carried out in only 3 min. The 1-ml sample is filtered under pressure in the 8-nm pore bag which has retention efficiency of 100% for cytochrome *c*.
Circle No. 45 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.



HPLC range. Pye Unicam. The LC-XP Series, a new range advanced, high performance liquid chromatography instruments, columns and accessories, has been launched by Pye Unicam. A modular design approach enables fully integrated systems to be supplied to suit specific requirements. Both isocratic and gradient elution liquid chromatographs are available. A completely new option is a fluorimetric detector, the LC-FL, which makes possible the high sensitivity selective detection of fluorescing compounds.
Circle No. 46 on Reader Enquiry Card.

Electron beam lithography system. Varian has introduced an electron beam lithography system which has air-to-air mask and wafer handling. Designated the Varian/Extrion model EBMG-20, the machine also features a four-position elevator in a vacuum chamber, which allows post-exposure curing of electron resists. The EBMG-20 system has the ability to expose any size mask up to 6 inches square. Hardware and software available enable direct exposure of wafers up to a 5-inch diameter.
Circle No. 47 on Reader Enquiry Card.

Removable needle syringes. Hamilton. A range incorporating a removable needle has now been added to the Hamilton 700 series syringes. This enables the user to replace bent or plugged needles in the field. The needle threads securely into place and cannot be pulled off by mistake and there is virtually no dead volume.
Circle No. 48 on Reader Enquiry Card.

Wafer cooling system. Varian has introduced a fixture for its Wayflow processing station. Called Waycool, this fixture operates by controlling the wafer temperature during ion implantation, and can boost throughput by as much as 500% for high doping level applications. Beam powers up to approximately 100W can now be used without appreciable wafer heating or degradation of photoresist materials.

APPOINTMENTS VACANT

MEDICAL RESEARCH COUNCIL
LABORATORY ANIMALS CENTRE
TWO RESEARCH OFFICERS

One post is in the Centre's Accreditation Department. Its duties will include visiting commercial breeders of laboratory animals throughout Great Britain who are accredited or recognised by the Centre.

One post is in the Director's Department and is concerned with a research programme into Specific Pathogen Free cats, with some administrative responsibility for the day-to-day running of the department.

Candidates for either post should have at least two years' postgraduate experience in biology or zoology, a knowledge of small animals would be an advantage but not essential. Salary according to age, qualifications and experience plus £354 London Weighting. Contributory Superannuation Scheme.

Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to. The Director, M.R.C. Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

MRC
Medical Research Council

9621(A)

UNIVERSITY OF NAIROBI
KENYA

Applications are invited for the post of

ASSOCIATE PROFESSOR
in the
DEPARTMENT OF CHEMISTRY

Applications are invited from candidates who have considerable experience in teaching and research as evidenced by published work. Candidates without a Ph D will not be considered. The appointee will be required to undertake academic leadership in the field of Inorganic Chemistry with regard to both teaching and research activities at undergraduate and postgraduate levels

Salary. K£3,864 to K£4,488 p.a. (K£1=£1.34 sterling) The British Government may provide salary supplementation of £5,784 p.a. (sterling) for married appointee or £3,876 p a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages Family passages, non-contributory medical scheme, S.S.S.F. or F S.S.U., housing allowance.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to the Registrar (Recruitment and Training), University of Nairobi, P.O Box 30197, Nairobi, Kenya, by April 1, 1979

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address.

Scientists and Research Assistants

We have vacancies for scientists and Research Assistants to join our Immunology Department. The Department is involved in the investigation of immunologic mechanisms in health and disease and the development of immunodiagnostic techniques. The programme of work covers interest in both veterinary and medical science.

We are looking for graduates and post-graduates with relevant experience to be involved in project teams.

Please write giving details of career history to:

Miss J. Kenny,
Recruitment & Career Development Manager,
Unilever Research,
Colworth Laboratory,
Unilever UK Central Resources Limited,
Colworth House,
Sharnbrook,
Bedford MK44 1LQ.

9669(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF DERMATOLOGY
CELL BIOLOGIST/BIOCHEMIST

Applications are invited for a Cell Biologist/Biochemist, required to join a small group studying the keratinisation of normal and pathological epidermis at the cellular and molecular levels. The successful candidate will be mainly involved with ultrastructural aspects of this work and some experience of the electron microscopy of tissues or proteins would be an advantage.

The position is available immediately and is supported, until December 31, 1983, by a programme grant from the Medical Research Council Initial appointment will be at a salary of £3,883 on range 1A of the salary scales for Research and Analogous Staff with superannuation benefit

Applications, enclosing curriculum vitae and the names and addresses of two referees, should be submitted to Dr D Skerrow, Department of Dermatology, Anderson College Building, 56 Dumbarton Road, Glasgow G11 6NU.

In reply please quote Ref No 4363M

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Egypt

As a result of an ODM mission to Egypt to undertake a pre-feasibility study of forage production and animal feeds a Team of three British Technical Cooperation officers are to be recruited to assist the Ministry of Agriculture, Arab Republic of Egypt, in the field of forage research and development.

Forage Agronomist

To review existing information on the agronomy of forage, fodders and other crops used for animal production in Egypt On the basis of field information to advise on an appropriate investigation programme aimed at improving production from existing species and assist in its implementation. Advise on the introduction of appropriate species of grasses, legumes, forages, fodders and other crops for trial and assist in the preliminary examination of these. In association with the Farm Systems/Farm Business Management Specialist, determine the potential value of existing and introduced species in improved farming systems and assist in their introduction and testing in such systems. Train counterpart staff in all aspects of the agronomic investigation programme. Develop proposals for a systematic programme of overseas training for counterpart staff in relevant fields of work. Applicants should have degree in agriculture or appropriate science with experience in tropical forage agronomy and the design, planning and execution of field experiments.

Appointment 2 years. Salary (UK taxable) in range £6400-£9500 pa plus variable tax free overseas allowance in range £570-£1575 pa (Ref 331X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference, stating post concerned, and giving details of age, qualifications and experience to:—

ODM

HELPING NATIONS HELP THEMSELVES

Electrophysiologist/ Neuro Pharmacologist

The Biology Department of ICI Pharmaceuticals has consistently been at the centre of the company's research into new formulations that will improve health. Considerable effort and investment is being put into the investigation of the basic mechanisms involved in the action of centrally acting drugs, analgesics and the discovery of psychotropic agents and drugs affecting respiration.

We need now to strengthen the department by appointing an Electrophysiologist/Pharmacologist. You will be a senior member of a team initially working closely with our analgesics group as well as collaborating with multidisciplinary teams of chemists and biochemists in the other areas referred to above.

You will establish and head a laboratory concerned with research in this field, and will need to have a background which demonstrates a proven record of relevant research in one of these areas combined with a good general knowledge of relevant electrophysiological techniques. The post will be attractive to a scientist who wishes to continue in a career devoted to research.

The Division's research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Conditions of service, salary and assistance given to married staff in moving house are designed to attract and retain staff of high calibre.

Applications in writing should be addressed to:

Mr. M. F. Losse,
Personnel Officer,
ICI Pharmaceuticals
Division,
Mereside Research
Laboratories,
Alderley Park,
Macclesfield, Cheshire

9671(A)

Chairperson Department of Oncology

Montefiore Hospital & Medical Center

We seek an outstanding Clinician-Scientist to fill this endowed position as the head of a distinguished hospital department. The missions include clinical care, specialty training of residents and fellows, and a major commitment to clinical investigation with basic science interaction. The candidate should be eligible for professorial appointment at the Albert Einstein College of Medicine. Salary and benefits appropriate to position are provided. All interested persons should submit a curriculum vitae and bibliography to:

Laurence Finberg, M.D.,
Chairperson, Search Committee,
c/o Department of Pediatrics,
Montefiore Hospital & Medical Center
111 E. 210th St., Bronx, NY 10467, USA.

Montefiore Hospital & Medical Center is an Equal Opportunity Employer M/F.

MEDICAL RESEARCH COUNCIL

LABORATORY OF MOLECULAR BIOLOGY

RESEARCH ASSISTANT

required to join a group working on chemical aspects of peptide synthesis. Candidates should possess a degree or equivalent qualification in chemistry, biochemistry, or a related science subject. Initial salary on the scale £3,261 (-4680) with good prospects for promotion to research officer grade and permanency.

Applications, giving details of qualifications, experience, and names of two referees should be sent to me at this address as soon as possible.

Dr R. C. Sheppard
MRC Laboratory of Molecular Biology
The Medical School, Hills Road
Cambridge CB2 2QH.

9633(A)

UNIVERSITY OF BATH

Applications are invited for a

LECTURER IN PHYSICS

Current research areas are Solid State Physics, Ultrasonics, Underwater Acoustics. Experience in one of these areas could be an advantage but other research interests would be acceptable.

Commencing salary will be set in the lower part of the range (£3,883 to £7,754 per annum).

Further particulars and application forms are obtainable from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 79/33/N. Closing date for applications: March 16, 1979.

9631(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOW

or

GRADUATE RESEARCH ASSISTANT

in the

DEPARTMENT OF BIOCHEMISTRY

The work, which is financed by M.R.C., will be concerned with the structure, biosynthesis and function of renal glycoproteins. Some experience with protein or carbohydrate chemistry is desirable but not essential. The successful applicant will have opportunity to study with others working in a variety of areas of glycoprotein research and collaboration with medical colleagues will be encouraged.

The appointment will be for three years. Commencing salary £3,883 per annum on Range IA of the national salary structure for research and analogous staff. Superannuation benefit.

Written applications (quoting R6/79) and naming two referees should be forwarded to Professor R. D. Marshall, Department of Biochemistry, University of Strathclyde, The Todd Centre, 31 Taylor Street, Glasgow G4 0NR, from whom further information may be obtained.

9619(A)

QUEEN ELIZABETH COLLEGE KENSINGTON

(University of London)

LECTURER IN BIOCHEMISTRY

Applications are invited for the post of Lecturer in Biochemistry who will be required to take part in undergraduate teaching programmes up to Final Year Honours standard. The department has a strong interest in human biochemical genetics; a research interest in the field of mammalian molecular genetics would be an advantage but is not essential, and applications from people with research interests in other areas are encouraged. Salary scale £3,909 to £7,754 per annum, starting salary depending on qualifications and experience. London allowance of £450 per annum is paid in addition.

Apply to the College Secretary, Queen Elizabeth College, Campden Hill Road, London W8 7AH, from whom further particulars and an application form may be obtained. Closing date: March 23, 1979.

(Potential applicants wishing to visit the department informally are asked to make an appointment with the secretary of the Department of Biochemistry.)

9662(A)

WESTMINSTER MEDICAL SCHOOL LEUKAEMIA

RESEARCH TECHNICIAN

Applications are invited from suitable persons for the post of Research Technician in the Department of Haematology at Westminster Hospital. The research concerns human bone marrow transplantation and treatment of leukaemia. The post gives the opportunity for obtaining the F.I.M.L.S. degree by thesis.

The salary and conditions of employment are comparable to those agreed by the Whitley Council.

Applications should be sent as soon as possible to Dr A. J. Barrett, Department of Haematology, Westminster Hospital, Dean Ryle Street, London SW1.

Intending applicants may visit the laboratory by appointment with Dr Barrett, 01-828 9811, ext. 2121.

9699(A)

Organic Chemist (PhD)

Roussel Laboratories Limited is part of an international group engaged in the manufacture and marketing of ethical pharmaceutical and allied products The research group of our R & D and manufacturing complex at Swindon, Wiltshire, forms an important part of the worldwide company research effort concerned with the discovery of new therapeutic agents

We have a vacancy for an Organic Chemist in the Chemical Research Department to undertake the design and synthesis of novel compounds for biological evaluation

The vacancy requires a person with innovative skills in preparative organic chemistry combined with a sound basic knowledge of chemistry Accordingly, candidates should have a good honours degree and have obtained recently or be in the process of completing a PhD degree in Organic Chemistry

Conditions of service are excellent, including generous assistance with relocation to this attractive part of Wiltshire

Please apply on our standard application form available from Rosemary Curtis, Assistant Personnel Manager, Roussel Laboratories Limited, Kingfisher Drive, Covingham, Swindon, Wilts SN3 5BZ.
Tel Swindon (0793) 24411

ROUSSEL

9615(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF THEORETICAL CHEMISTRY
THEORETICAL STUDIES OF ELECTRON-MOLECULE COLLISIONS (DISSOCIATIVE RECOMBINATION PROCESSES)
(Re-advertisement)

Applications are invited for a Science Research Council-supported postdoctoral research assistant to work on theoretical calculations of electron-molecule collision processes of the type $e + AB^+ \longrightarrow AB^* \longrightarrow A + B$, with particular emphasis upon non-adiabetic (curve crossing) effects The project is initially funded for 21 to 23 months (depending upon initial salary), with prospect of further extension. The work will also include co-operation with Professor P G Burke's research group at Daresbury Laboratory Applicants should write as soon as possible to Dr J Gerratt, Department of Theoretical Chemistry, University of Bristol, Bristol BS8 1TS, enclosing curriculum vitae and names and addresses of two referees 9613(A)

Hampshire Area Health Authority
SOUTHAMPTON GENERAL HOSPITAL

Applications are invited for the post of Basic Grade Biochemist in the University Department of Chemical Pathology and Human Metabolism The post offers good opportunities for development and research work in trace metal analysis, and is initially for a period of three years The position would best suit a graduate with a strong chemistry background Whitley Council conditions of service apply. Salary scale £2,991 to £4,899 depending on qualifications and experience

Job description, further particulars and application forms are available from Personnel Department, Tremona Court, 30-32 Tremona Road, Southampton. Telephone Southampton 777222 Ext 3556 Arrangements to visit the department may be made with Mrs B Loyd, Southampton General Hospital Telephone Southampton 777222 Ext. 3922 Closing date February 28, 1979 9653(A)

Agriculture & Horticulture
LIFE SCIENTIST?
Become a Specialist Adviser

The Science Service of the Agricultural Development and Advisory Service provides farmers and growers with a wide range of vital technical information and advice which is supported by investigation and development work carried out from 12 regional centres across the country

Opportunities currently exist for graduates to become Specialist advisers in the following science disciplines Full training will be given where necessary

MICROBIOLOGY

Study of micro-organisms of importance in the production, processing, preservation and storage of farm and horticultural products, treatment and disposal of waste products and effluents; bacterial pathogens causing plant disease, hygiene of dairy products and quality control of farm water supplies *Ref. S(H)906*

ENTOMOLOGY

Primarily, the diagnosis of causes of pest damage to crops, identification of these pests, assessment of their importance and significance, and recommendations for prevention and control *Ref. S(M)906*

PLANT PATHOLOGY

Diagnosis of plant diseases caused by fungi, bacteria and viruses Special interest in the assessment of the damage done and losses caused by plant diseases, and in seeking preventive or control measures *Ref. S(K)906.*

NUTRITION CHEMISTRY

Nutrition of farm animals, the nature and composition of feeding stuffs, formulation of rations for livestock, and biochemical aspects of the cultivation, processing, preservation and use of animal feeds *Ref· S(J)906*

SOIL SCIENCE

Primarily, all aspects of soils—physical, chemical and biological—that affect the nutrition, growth and production of agricultural and horticultural crops This involves both field advisory work and investigations to study conditions of optimum production and the reasons for partial or complete failures in crop production *Ref S(L)906*

Candidates, normally aged under 28, should have a good honours Degree or equivalent in an appropriate dicipline *Final year students may apply*

Salary, starting between £2,995 and £3,810, according to age, qualifications and experience, rises to £3,920 Promotion prospects Non-contributory pension scheme

Write for full details and application form (to be returned by 16 March 1979) to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours) *Please quote appropriate reference*

Men and women may apply 9688(A)

Agricultural Development and Advisory Service.

Ministry of Agriculture, Fisheries and Food

Head of Biochemical Research

As a result of the Company's policy of offering challenging careers to its scientists in every sector of its business, a senior position will shortly become vacant within the group's Central Research Laboratory at Luton. This is a crucial and demanding job as it covers the whole of the Company's analytical and biochemical research, and the application of this work to the production principally of beer, but also of spirits, wines and soft drinks.

Further responsibilities and development of the career of the chosen person will depend as much on the individual as on the Company's expanding activities.

We are therefore looking for a well qualified, young scientist who has already demonstrated an aptitude for research, an inventive mind and the ability to apply it where it matters most – in production.

Remuneration will reflect both the seniority of the position and the experience of the successful applicant.

Applications should be sent to:
Miss P. M. Donnelly, Personnel Officer,
Whitbread & Co. Limited, The Brewery,
Chiswell Street, London EC1Y 4SD.
Telephone: 01-606 4455.

9679(A)

WHITBREAD

AGRICULTURAL RESEARCH COUNCIL

Poultry Research Centre
West Mains Road
EDINBURGH EH9 3JS

Applications are invited for the following vacancies:

CHEMIST/BIOCHEMIST/NUTRITIONIST

A Chemist/Biochemist with relevant nutritional experience is required by the Nutrition Department at the above Centre. The appointee will work on the evaluation of feedstuffs as energy sources for poultry. The primary objective will be to understand digestive and metabolic processes which influence and limit energy values of feedstuffs and the potential for modifying these limits. Definition of energy values and the development of experimental methodology will also be involved. Close liaison with scientists working on energy metabolism would be envisaged. (Ref. No. 796.)

Nutritionist or Biochemist with a special interest in whole animal metabolism and simulation modelling is required by the Nutrition Department at the above Centre. The appointee will work on the development of simulation models of biological processes which are relevant to poultry nutrition and production. Initially, models of metabolism in the growing animal will have the highest priority. Research work on the biochemical/metabolic level will support model development. Candidates may have a variety of experience or interests but must demonstrate an ability to relate "whole animal" metabolic and biochemical concepts to practical nutritional decisions and must have a genuine interest, and preferably some experience, in the use of computer modelling techniques in biology. (Ref. No. 797).

Qualifications: 1st or upper 2nd class honours degree and preferably a Ph.D.

Salary: In the scale £4,101 to £5,448 at H.S.O. level and £5,154 to £6,898 at S.S.O. entry. Entry at the higher level requires at least 4 years postgraduate experience. Non-contributory superannuation scheme. 22 days annual leave, plus 10½ public/privilege holidays.

Application forms can be obtained from the Secretary at the above address. These should be completed and returned to him not later than Friday, March 16, 1979, quoting our reference number.

9692(A)

PUBLIC HEALTH LABORATORY SERVICE BOARD

P.H.L.S. Centre for Applied Microbiology and Research
Porton Down

Applications are invited from experienced microbiologists for two senior posts in the rapidly expanding field of microbiological laboratory safety.

1. A **Senior Grade Microbiologist** to act as the Deputy Safety Officer for the Centre and to be responsible for the monitoring of equipment, facilities and experimental procedures within the Centre. Additionally, he/she will be largely responsible for devising and implementing training programmes in microbiological laboratory safety.
2. A **Senior Grade Microbiologist/Chief Medical Laboratory Scientific Officer** is required to undertake research into and development of methods of assessing the safety of equipment, facilities and experimental procedures, including the stability of airborne microorganisms. He/she will be expected to contribute to the training programmes in microbiological laboratory safety, offered by the Centre.

In addition to demonstrated abilities as microbiologists, the successful candidates will be expected to have a good knowledge of safety legislation and codes of practice relevant to microbiological laboratory procedures.

Some experience in the monitoring and use of radio-isotopes would be an advantage. There may be a requirement for the successful candidates to travel to hospitals and other laboratories to participate in tests of equipment or facilities on site.

Salary scales: Senior Grade Microbiologist, £5,451 to £6,837; Chief Medical Laboratory Scientific Officer, £5,472 to £6,192.

The appointments will be under P.H.L.S. (N.H.S.) terms and conditions of service.

Further details of the posts may be obtained from Dr R. A. Bassett, Public Health Laboratory Service, 61 Colindale Avenue, London NW9 5EQ, to whom applications with full career details and the names and addresses of three referees, should be sent by March 15, 1979. 9694(A)

UNIVERSITY OF EDINBURGH

Faculty of Medicine
DEPARTMENT OF BIOCHEMISTRY

UNIVERSITY DEMONSTRATOR

Applications are invited for the post of University Demonstrator which is tenable from October 1, 1979, or earlier by arrangement.

The initial salary will be at a suitable point on the scale £3,384 to £4,882 p.a.

The major duties of the University Demonstrator will be to participate in teaching medical, dental or science students and to engage in independent or collaborative research.

Further particulars may be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (six copies), including the names of two referees, should be lodged not later than March 31, 1979.

Please quote: Reference 1017.

9691(A)

THE UNIVERSITY OF HULL

DEPARTMENT OF ZOOLOGY

Applications are invited for a Lectureship in the Department of Zoology from October 1, 1979. The Lectureship has been established to complement the team of existing members of staff with expertise in vertebrate physiology who collectively will provide a course in Human Physiology for the newly instituted Honours School in Zoology. The successful candidate will have a good honours degree in Zoology, Biochemistry or Physiology and/or be medically qualified in the general area of physiology and have demonstrated a capacity for independent research in a major area of physiology.

Salary for non-medically-qualified candidates within the scale £3,883 to £7,754 per annum (under review) plus U.S.S. benefits.

Applications (six copies) giving details of age, qualifications and experience, together with the names of three referees should be sent by March 8, 979 to the Registrar, The University of Hull, Hull, HU6 7RX from whom further particulars may be obtained.

9601(A)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF CHILD HEALTH

Applications are invited for the post of LECTURER in DEVELOPMENTAL BIOLOGY in the Department of Child Health. The Department (Professor David Hull) was established in September 1972.

The succesful applicant should have experience of research into the biology of the foetus and the newborn in both animals and man and to be familiar with both physiological and biochemical methodology. He/She should also have had some experience of undergraduate and postgraduate teaching.

Salary will be on the non-clinical lecturer scale with membership of U.S.S. The starting salary will depend on qualifications, age and experience. The successful candidate will be expected to assume duty as soon as possible.

Other particulars and a form of application may be obtained from the Deputy Registrar, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, to whom completed applications should be returned by the March 1, 1979. 9599(A)

UNIVERSITY
FACULTY
OF SCIENCE

Lectureship in Biology

Applications are invited for a tenured lectureship in Vertebrate Physiology. The person appointed will be involved in the preparation and maintenance of the Biology Discipline's 2nd and 3rd level courses in Physiology, and will be expected to take an active interest in the development of the discipline's future offerings in the field of continuing education He/she will be expected to undertake research either independently or in association with one of the existing research groups in the discipline The successful candidate should have a good research record and teaching experience in a physiological area

Commencing salary will be within the lecturer scale £3,883 to £7,754 p a with U S S benefits

Application forms and further particulars are available from The Recruitment Office (JD3661/2), The Open University, P O Box 76, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404 there is a 24 hour answering service on 63868 Closing date for applications 1st March 9609(A)

UNIVERSITY OF EXETER
DEPARTMENT OF PHYSICS

Applications are invited for a post of Lecturer in Physics tenable from October 1, 1979 The research field of interest is Medical Physics Preference will be given to applicants with experience in hospital departments

Commencing Salary within the range £3,883 to £5,604 p.a (under review), on the salary scale £3,883 to £7,754 p a (under review) Further particulars may be obtained from Miss Doreen Watson, University of Exeter, Northcote House, Exeter, EX4 4QJ to whom applications (8 copies) should be sent by March 2, 1979 Please quote reference No 3199 9598(A)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the post of

LECTURER/ ASSISTANT LECTURER

in the

DEPARTMENT OF CHEMISTRY

Applicants with interest in one or more of the following Photochemistry, Electrochemistry, Radiochemistry or Gas Phase Kinetics would be preferred and an interest in energy studies would be an added advantage. The appointment is for three years to September 30, 1982.

Salary scale Lecturer, J$8,913 to J$13,917 p a, Assistant Lecturer, J$7,236 to J$7,926 p.a. (£1 sterling= J$3 38). F.S S.U. Study and Travel Grant Unfurnished accommodation will be let by the University at a rental of 10% of salary, or a housing allowance of 20% of salary will be paid Family passages.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent direct as soon as possible to the Registrar, University of the West Indies, Mona, Kingston, Jamaica

Applicants resident in the UK should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address 9696(A)

Human Pharmacokinetics (Study Co-ordinator)

May & Baker Ltd. is an international Company, manufacturing and marketing a wide range of research based pharmaceutical products.

A vacancy has arisen for a Study Co-ordinator, reporting to the Head of the Pharmacokinetic Section of the Drug Metabolism Department, at Dagenham, Essex. The work involves the setting up, programming and monitoring of pharmacokinetic studies in healthy human volunteers and patients, in such a way that the studies are conducted according to the highest international standards. When available, the successful applicant will assist in the analysis of biologial samples and in the pharmacokinetic-analysis of results obtained.

The studies will be conducted both "in-house" and in collaboration with the Clinical Pharmacology units of several hospitals.

The successful applicant will be scientifically trained in an appropriate discipline, with good organisational ability and capable of working independently. He/she should be a graduate or an experienced technician with, ideally, a current driving licence.

Please telephone 01-592 3060 extension 2506 for an application form or write with full details of age, experience, qualifications and present salary to

M&B May&Baker

Mrs. P. M. Clark, Personnel Officer, (Scientific Staff), May & Baker Ltd., Dagenham, Essex RM10 7XS, quoting reference number 12/N/1 9663(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of

PROFESSOR IN BOTANY

Applicants should possess a Ph D or equivalent in Botany with at least ten years of teaching at University level. Applicants must also have had considerable research experience as evidenced by published work in any of the important areas of plant sciences They should also have a capacity for exercising leadership in undergraduate and postgraduate work as well as considerable administrative experience.

Salary scale. K£4,632 to K£5,562 p a (K£1=£1 34 sterling) The British Government may supplement salary by £6,552 p a. (sterling) for married appointee or £4,644 p a (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages Family passages. superannuation scheme, medical aid scheme, various allowances

Detailed application (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of Nairobi, P O. Box 30197, Nairobi, Kenya, by April 5, 1979

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address 9695(A)

COLEG PRIFYSGOL CYMRU THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

LASER STUDIES IN CHEMICAL PHYSICS

Following the award of a major grant from the Science Research Council to promote the application of new laser systems to spectroscopy, we wish to invite applications for the following appointments (from 1 April, 1979, or as soon possible there-after);

1. TWO POST-DOCTORAL RESEARCH ASSOCIATES, Grade 1A, starting salary in the range £3,883 to £4,382 depending on age and experience; (2 year appointments).

2. ONE POST-GRADUATE RESEARCH ASSISTANT, Grade 1B, starting salary in the range £3,384 to £3,883. (3 year appointment). Holders of this position may be eligible to submit for a higher degree of the University of Wales.

The persons appointed will be expected to work in a laser group encompassing the research interests of Professor W. J. Jones, Dr. P. A. Freedman, Dr. J. O. Williams and Professor G Williams. A wide range of lasers and spectroscopic instrumentation is available to promote studies in (a) time-resolved photochemistry and photophysics utilising a synchronously-pumped mode-locked/cavity-dumped argon ion-dye laser system (P.G.R.A and one P.D.R.A.) and (b) the spectroscopy of gaseous molecules cooled to near 0K in a supersonic jet (one P.D.R.A.).

Application forms and further particulars may be obtained from The Registrar, The University College of Wales, Old College, King Street, Aberystwyth SY23 2AX to whom completed application forms should be submitted as soon as possible. 9642(A)

Senior Scientific Officer/ Higher Scientific Officer/ Scientific Officer

£2,839 to £6,898

Applications are invited for a pensionable post in the Plant Pathology Division of the Department of Agriculture situated at Newforge Lane, Belfast.

The successful candidate will be expected to take part in research on crop disease problems (primarily horticultural) and to assist in the provision of a specialist advisory service. The person appointed may also be required to undertake teaching duties in the Faculty of Agriculture and Food Science, Queens University, Belfast.

Senior Scientific Officer

Over 25 and under 32 years of age on December 31, 1979, with a 1st or 2nd class honours degree in Botany or Microbiology and at least 4 years' relevant postgraduate experience.

Higher Scientific Officer

Under 30 years of age on December 31, 1979, with an honours degree as above and at least 2 years' appropriate postgraduate experience.

Scientific Officer

Under 27 years of age on December 31, 1979, with an honours degree as above.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including the level of academic attainment and relevant experience) to be best qualified.

Salary scales

Senior Scientific Officer	£5,154 to £6,898
Higher Scientific Officer	£4,101 to £5,448
Scientific Officer	£2,839 to £4,415

(The salary scales will be subject to review from April 1, 1979.)

Grading and starting salary will be related to qualifications and experience.

There are prospects of promotion to Principal Scientific Officer, £6 609 to £8,461.

Please write or telephone for an application form quoting job reference SB 105/79/NM to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than March 2, 1979. 9656(A)

NORTHERN IRELAND
CIVIL SERVICE

UNIVERSITY OF EDINBURGH
LECTURER IN SEED TECHNOLOGY

The Edinburgh School of Agriculture invites applications for a University Lectureship with responsibility for the M.Sc./Diploma Course in Seed Technology. This [illegible] month postgraduate course, which is supported by ODM, has emphasis on technical management for seed production, particularly overseas. Applicants should be University graduates with experience of seed production overseas. This is a three year appointment, in the first instance, commencing at the latest from October 1979 on the Lecturer scale £3,883 to £7,754 per annum.

Further particulars can be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL. Applications should arrive, if possible, not later than 17 April 1979. Please quote Reference 1013.

9629(A)

KING'S COLLEGE HOSPITAL

DEPARTMENT OF HAEMATOLOGY

A Graduate Research Assistant to participate in a three year project investigating the immunological and cytochemical properties of lymphoid cells in malignant disorders. Training will be given in the necessary techniques and it is possible that the project will provide the basis for a higher degree.

The appointment will be tenable from April 1, 1979 for one year in the first instance, renewable annually.

For further details, contact Dr M. V. Joyner on 01-274 6222 ext. 2735. Application form and job description available from the District Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS. Tel: 01-274 6222 ext. 2254.

Closing date: March 2, 1979.

9676(A)

BIOCHEMICAL SOCIETY

Applications are invited for a senior post in the Society's Editorial Office. The post involves responsibility for editorial processing of material for the **Biochemical Journal** and other Biochemical Society publications, and the successful applicant will be required to act as a deputy for the Editorial Manager. As well as a degree in biochemistry or related subject it is essential that candidates (probably of age 35-45) should have had sound postgraduate experience of scientific editorial work and academic publishing and be capable of supervising the work of others. A salary commensurate with the seniority of this post will be offered. Please apply in writing, giving the names of two referees, to the Eexcutive Secretary, Biochemical Society, 7 Warwick Court, London WC1R 5DP.

9622(A)

SENIOR HISTOPATHOLOGIST
THE ST GEORGE HOSPITAL
with conjoint appointment as Clinical Professor or Clinical Associate Professor
School of Pathology
University of New South Wales Australia

Suitably qualified medical practitioners are invited to apply for appointment as Senior Histopathologist at this 550 bed teaching hospital of the University of New South Wales. The appointee may also be offered the title of Clinical Professor (conjoint appointment) or Clinical Associate Professor (conjoint appointment) and as such would be responsible to the University of New South Wales for teaching in the School of Pathology, with access to the facilities of that school.

The Histopathology Division provides a comprehensive service to the Hospital and is staffed with a second full-time specialist and two Registrars. A full-time Senior Lecturer in Pathology is also on site.

Salary is at the Senior Staff Specialist rate, currently $A39,364 p.a. Other conditions in terms of the Medical Officers' Hospital Specialists' (State) Award include study leave of three months for each five years' service and limited right of private practice in terms of the procedures laid down by the Health Commission of New South Wales.

Written applications, including the names and addresses of three referees close with the Chief Executive Officer, The St George Hospital, Kogarah, 2217, on April 12, 1979. Enquiries concerning hospital duties should be directed to the Medical Superintendent, The St George Hospial, phone (02) 588 1111, and on Uiversity matters to Professor A. Lykke (02) 662 2770.

9537(A)

CHILDREN'S HOSPITAL BIRMINGHAM
TECHNICIAN OR BIOLOGICAL SCIENCE GRADUATE

required for a research post. The successful applicant will be concerned with a leukaemia and non-Hodgkins Lymphoma study. Previous experience in immunology helpful but not essential. Appointment for one year in the first instance.

Salary according to experience and qualifications.

For further details and an application form please contact Dr F. G. H. Hill, Consultant Haematologist, Haematology Department, The Children's Hospital, Ladywood Middleway, Birmingham B16 8ET. Telephone: 021-454 4851. Closing date: March 15, 1979. 9590(A)

PROFESSOR OF BIOCHEMICAL PHARMACOLOGY AND CHAIRPERSON
DEPARTMENT OF PHYSIOLOGY BIOCHEMISTRY AND PHARMACOLOGY

The New York State College Veterinary Medicine at Cornell Un versity invites nominations and applica tions for the position of Chairperso of the Department of Physiology, Bi chemistry and Pharmacology. Th speciality of the applicant should within the discipine of biochemica pharmacology. Credentials shoul include evidence of outstandin research achievements and potentia administrative ability and considerab teaching experience, and there shoul be a demonstrated commitment to e cellence in teaching and research.

The department is multidisciplinar with responsibility for teaching, r search and service. The 17,000 squar feet of teaching and research labor tory space and 6,000 square feet specialised animal-holding space a well-equipped for research and instru tion on a wide range of subjects an species. The department is also engage in interdisciplinary research projec and training programmes in toxicolog and comparative gastroenterology.

Applicants should submit thei curriculum vitae, and request that thre letters of recommendation be sen directly to the Search Committe Applications accepted through June 1979.

(University of London)

POSTDOCTORAL RESEARCH ASSISTANT

urgently required for a Medical Research Council three-year project in the Department of Structural Biology to work on fine structure and histochemistry of fracture healing in long bones. Candidates should have qualifications in Biology or Zoology and be competent in all aspects of preparative techniques for, and the use of, a transmission electron microscope.

Salary in the range £3,883, £4,133, £4,382 plus London allowance £450 per annum.

Application forms and further particulars available from the Establishment Officer, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.

9683(A)

ROTHAMSTED
EXPERIMENTAL STATION
Harpenden, Herts, AL5 2JQ

SCIENTIFIC OFFICER

required to assist in a research programme concerned with virus diseases of grasses and legumes. Responsibilities will include laboratory, glasshouse and field work on virus diseases of ryegrass, clovers and field beans.

Qualifications: Pass degree, HNC or equivalent in biological sciences related to crop production. Experience in handling viruses and/or virus vectors and in field experimentation desirable but not essential. Driving licence.

Appointment in grade of Scientific Officer, £2,839 to £4,415 per annum. Starting salary according to qualifications and experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 387 by March 15, 1979. Further details on request. 9687(A)

Wellcome

Chemist/Biochemist

Veterinary Research

Applications are invited from young postgraduates, probably aged 25-35, to work as a Scientist within a multi-disciplinary team, studying the ways in which penetration, tissue distribution, and metabolism are involved in resistance to insecticides.

Candidates should possess an honours degree in either Chemistry and/or Biochemistry and have experience in the use of modern analytical techniques, especially with regard to the estimations of compounds at very low levels.

The Laboratories are part of The Wellcome Group Research and Development and are concerned with veterinary pharmaceuticals and control of insect pests. They are situate on the outskirts of Berkhamsted. In addition to an attractive salary, the Group offers excellent conditions of employment including assistance with relocation expenses where appropriate.

If you are interested, please write or phone for an application form, quoting reference NA.2, to: A. J. Morris, Site Personnel Officer, The Wellcome Foundation Limited, Ravens Lane, Berkhamsted, Herts. Tel: Berkhamsted 3333, ext. 363.

1976

9661(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the following posts in the DEPARTMENT OF AGRICULTURAL ECONOMICS

PROFESSOR/ASSOCIATE PROFESSOR/SENIOR LECTURER/LECTURER

Applicants should have a Ph.D., preferably with emphasis on Agricultural Economics. Experience in an African or other developing country preferred. Duties include conducting lectures and tutorials in Agricultural Economics, Marketing and Agricultural Policy for undergraduate students, plus initiating research or continuing current research into agricultural performances and policy in Zambia.

Salary scales: Professor K8,616 to K9,135 per annum, Associate Professor K8,232 to K8,616 per annum; Senior Lecturer K7,603 to K8,016 per annum; Lecturer K4,956 to K7,608 per annum (£1 sterling=K1.56). The British Government may supplement salaries in range £2,922 to £5,952 per annum (sterling) for married appointees and £930 to £3,366 per annum (sterling) for single appointees (reviewed annually and free of tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; medical aid scheme; regular overseas leave. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia by March 31, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9638(A)

BUSH BOAKE ALLEN LIMITED
a division of
ALBRIGHT AND WILSON LIMITED
have a vacancy in the Process Technology Department
of the Flavour Laboratories at Walthamstow
London E17 for a

SENIOR PROCESS TECHNOLOGIST

The principle duties of the successful candidate will be to follow lines of research in connection with onion flavours. In particular he/she will study the relationship between varieties and stages of maturity of onions with their yields of flavour precursors.

Applications are invited from candidates aged 24+ with a good academic knowledge probably at post-graduate level. Experience with natural products and their chemistry and handling is essential. A knowledge of, or experience with H.P.L.C. is desirable.

An attractive salary will be offered in addition to a range of employee benefits which include a non-contributory pension scheme.

Applications in writing to:

R. J. Saunders
Recruitment and Training Manager
BUSH BOAKE ALLEN LTD.
Blackhorse Lane
Walthamstow E17
Tel: 01-531 4211

stating age, qualifications and experience.

9689(A)

Institute for Marine Environmental Research

SCIENTIFIC OFFICER
HIGHER SCIENTIFIC OFFICER
SENIOR SCIENTIFIC OFFICER

The staff of the Institute comprises multi-disciplinary teams for research on ecology of open seas and estuaries, and effects of stress and pollution Investigations in the field and by laboratory experiments include analyses of variability in natural populations and climate, quantification of ecosystem processes, formulation of mathematical simulation models and derivation of indices of environmental quality. There are four vacancies at Plymouth:

Post 293—Microbiology: for research on heterotrophic and autotrophic processes in open seas and estuaries in relation to ecosystem dynamics, organic substrates, and nutrient herbivore and detritivore cycles. Candidates preferably with post-graduate experience in microbiology and related organic chemistry.

Post 305—Statistics: to provide a consultative service, participate in statistical design, analyses and interpretation, and to develop methods for marine ecological research. Candidates preferably with experience in application of probability statistics to research in natural sciences.

Post 328—Computing: for management and development of software for research in marine ecology; also operation of two PDP-11s (RSTS/E and RSX-11M); supervision of one assistant and two data processors Candidates preferably with experience of software development for research, knowledge of FORTRAN and BASIC

Post 330—Mathematical modelling: to participate in multidisciplinary research teams, to develop deterministic and stochastic models of marine ecosystems. Candidates preferably with post-graduate experience in mathematical ecology

Academic Qualifications: For Posts 293, 305 and 330, a good Honours degree in an appropriate subject. For Post 328 a degree, HNC or HND in computing science plus relevant experience Ability to work at sea in research vessels and small boats is essential for Post 293 and would be an advantage for the other posts.

At least two years' relevant postgraduate experience is required for appointment as Higher Scientific Officer. Candidates with less or more experience may be appointed as Scientific Officer or Senior Scientific Officer, respectively.

Salary: SO—£2,839 to £4,415; HSO—£4,101 to £5,448; SSO—£5,154 to £6,898. Starting salary may be above the minimum

Staff of the Council are not Civil Servants but pay and conditions are similar to those of the Civil Service, including a non-contributory pension scheme.

For further particulars and application forms, please write, quoting the Post Number, to The Director, Institute for Marine Environmental Research, Prospect Place, The Hoe, Plymouth PL1 3DH.

Natural Environment Research Council

SOMERSET LEVELS PROJECT
RESEARCH ASSISTANT

required for palaeobotanical investigations of prehistoric environments in the Levels. Position tenable in the Department of Archaeology, University of Cambridge.

Salary approximately £3,000 per year; starting date, April 1, or negotiable.

Further details from:

Dr J. Coles
Department of Archaeology
Downing Street, Cambridge

Closing date: March 5.

9693(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF ZOOLOGY

Applications are invited for the post of

LECTURER IN ANIMAL BEHAVIOUR

tenable from October 1, 1979 Candidates should have field experience and be able to assist with ecological teaching and with the development of Joint Honours courses with Psychology and Anthropology

Salary on the scale £3,883 to £7,754 per annum (under review) plus U S.S. Applications (3 copies) naming three referees, should be sent by February 23, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

9463(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of

RESEARCH ASSOCIATE

to participate in research with Dr S. J Ferguson on a biochemical investigation of the Bioenergetics of Paracoccus denitrificans

Starting salary will be in the range £3,384 to £3,883 per annum (plus U S.S.).

The post, which is supported by the S.R.C , is to be filled as soon as possible, and is available for a maximum of three years

Applications (2 copies) including names of 2 referees to Miss L R. Heyes, Senate Registry, University of Birmingham, P.O Box 363, Birmingham B15 2TT, from whom further particulars may be obtained

Closing date. March 9, 1979.

9682(A)

UNIVERSITY OF LEICESTER
DEPARTMENT OF PHYSICS

RESEARCH DEMONSTRATOR

Applications are invited for a post of Research Demonstrator in Condensed Matter Physics. He/she will be required to undertake, under the direction of the Head of Department, tutorial or demonstrating work within the Department up to a maximum of twelve hours a week, he is not expected to give lecture courses The successful applicant will be required to work for the degree of Doctor of Philosophy with the condensed matter physics group. The interests of the group include the study of disordered matter and of metal surfaces

Salary within the range £3,215 to £3,384 to £3,634.

Further particulars from the Registrar to whom applications on the form provided should be sent by April 1, 1979

9678(A)

MEDICAL RESEARCH COUNCIL
BIOCHEMICAL PARASITOLOGY UNIT
MOLTENO INSTITUTE
UNIVERSITY OF CAMBRIDGE
RESEARCH TECHNICIAN

to assist a group studying the biochemistry of parasitic protozoa The work involves operation and basic maintenance of an analytical ultracentrifuge. Microbiological/Biochemical training and experience in optical/photographic systems essential HND or equivalent required.

Salary range £3,190 to £3,838 (under review)

Applications to The Director, Medical Research Council Biochemical Parasitology Unit, The Molteno Institute, University of Cambridge, Downing Street, Cambridge CB2 3EE.

9686(A)

QUEENSLAND INSTITUTE OF TECHNOLOGY
Brisbane—Australia
HEAD OF SCHOOL OF APPLIED SCIENCE

The Institute is seeking a suitable person to fill this senior post Salary is $A33,061 per annum. Full details are available from the Agent-General for Queensland, 392 The Strand, London WC2R 0LZ or telephone (01) 836 3224

Written applications quoting V. 22/79 together with telephone contacts, full details and the names of three referees should reach the Personnel Officer, Q I.T , George Street, Brisbane 4000 Australia by May 18, 1979

RESEARCH OFFICERS
(2 posts)

The Institute invites applicati
from suitably qualified candidates
two research posts within its Appl
Nutrition Department

1. The successful applicant for
first post would be expected
work on aspects of the nutriti
of cattle, paying particular att
tion to optimalising the use
resources in the production
meat.
This post will be in the Sen
Scientific Officer (£5,154 to £6,
per annum) or Principal Scient
Officer (£6,609 to £8,461
annum) grades and starting sal
depends on experience. At le
four years' postgraduate expe
ence is required in relevant fie
of research.
2. The second post is for a per
who would be expected to stu
the nutrition of the very you
pig with particular reference
amino acid requirements
their relationships to the dieta
energy supply.
This appointment will be
Scientific Officer (£3,294 to £4,
per annum) or Higher Scienti
Officer (£4,101 to £5,448
annum) grades and starting sal
depends on experience At le
two years' relevant postgradu
experience is required for H.S
grading.

Qualifications required: First
upper second class honours degree
one of the biological sciences or
agriculture, and an interest in
practical application of science in
animal industry.

There is a non-contributory pensi
scheme.

Further details of the post may
obtained from the Secretary of
Institute, to whom applications shou
be submitted together with the nam
of two people to whom reference c
be made Closing date March 16, 19

UNIVERSITY OF GLASGO
DEPUTY RADIATION PROTECTION OFFICER

Applications are invited for
above appointment in the Univers
Radiation Protection Service. Ap
cants, preferably with a degree
physics, should have several years'
perience in operational health phys
or in handling radioisotopes and
capable of dealing with all aspects
radiological protection in the Univ
sity

The successful applicant, under
overall supervision of the Radiati
Protection Officer, will be responsil
for the day-to-day operation of
University Radiation Protection S
vice. Duties will include advising
the safe use of radioisotopes, X-r
machines, lasers and U.V. sourc
conducting routine surveys of rad
tion areas, assisting with the dispo
of radioactive waste, coping with ra
ation emergencies, maintaining hea
physics records, and supervisi
ancillary staff.

To maintain the good worki
relationship which exists between
Service and the departments it serv
preference will be given to candida
of suitable personality with an abil
to liaise and communicate with work
in other disciplines

Salary will be at an appropri
point on Grade 1A (£3,883 to £6,5
interim) of the salary scales for Ot
Related Staff.

Further particulars may be obtai
from the Secretary of the Univers
Court, (Room 18), University
Glasgow, Glasgow G12 8QQ, w
whom applications (8 copies), toget
with the names and addresses of t
referees, should be lodged not la
than March 8, 1979

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
SENIOR LABORATORY SCIENTIFIC OFFICER/ LABORATORY SCIENTIFIC OFFICER

Required in the Department of Biochemistry to take charge of the Undergraduate Teaching Laboratory. The appointee will be expected to be totally responsible for the preparation work for Pre-Clinical Medical and Dental Classes during term-time. A part-time appointment might be possible.

Full-time salary, according to experience, in the range:—

Laboratory Scientific Officer: £3,261 to £4,680 plus £354 London Weighting p.a.

Senior Laboratory Scientific Officer: £4,347 to £5,769 plus £354 London Weighting p.a., together with superannuation.

Enquiries to Dr. C. W. Parr, Tel. 01-247 0644 Ext. 20. Applications to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, quoting Ref. B/1/79.

9603(A)

UNIVERSITY OF LONDON
READERSHIP IN PHYSIOLOGY AT QUEEN ELIZABETH COLLEGE

The Senate invites applications for the above Readership to be held at the Department of Physiology (Head of Department: Professor D. L. Yudilevitch, M.D.). The Reader will be an experienced physiologist of proven research ability. The Department has been expanding its research activities in the past few years and is now well-equipped for studies in its current interests. Queen Elizabeth College is located in Kensington in a pleasant neighbourhood near Holland Park.

The successful candidate will be expected to develop his/her own research, supervise postgraduate research students and to contribute to undergraduate teaching.

Applications (10 copies) must be received not later than March 30, 1979, by the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars (including the salary scale) should first be obtained.

9684(A)

UNIVERSITY OF THE WEST INDIES—BARBADOS

Applications are invited for the post of PROFESSOR/SENIOR LECTURER IN THE DEPARTMENT OF BIOLOGY. Duties to be assumed as soon as possible and not later than September 1, 1979.

Salary scales: Professor (in the range), BDS$36,729 to BDS$45,480 per annum: Senior Lecturer: BDS$25,827 to BDS$34,017 per annum (£1 sterling= BDS$3.99). F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10% of salary. A housing allowance of 20% of salary is payable to staff who make their own housing arrangements. Family passages. Study and Travel Grant. Detailed applications (three copies) with curriculum vitae and naming three referees should be sent direct as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

9637(A)

RESEARCH ASSISTANT

to work on the Biochemistry of Sickle Cell Disease. Salary on the Whitley Council Scale. Please apply to the Secretary, U.C.H. Medical School, University Street, London WC1E 6JJ quoting reference RA/EH. 9639(A)

SENIOR RESEARCH APPOINTMENTS

BERKELEY NUCLEAR LABORATORIES

Applications are invited for two posts of Division Head at the CEGB's Nuclear Laboratories at Berkeley in Gloucestershire. The function of the Laboratories is to provide the necessary technical and scientific support to Plant Operation, Construction, Commissioning and Forward Ordering of new plant as part of the CEGB's expanding nuclear power programme. The Laboratories have the full range of facilities expected of a major industrial laboratory.

Division Heads report directly to the Director of the Laboratories and are responsible for the initiation and effective management of a broad range of research programmes. With these two appointments, the Laboratories will be organised as five scientific divisions and appropriate supporting groups, with a total staff of 720 of whom 280 are graduate scientists and engineers.

The range of technical disciplines involved in the Laboratories research programmes is very wide and thus candidates with good academic qualifications in any of the engineering or physical sciences will be considered. More important than the candidate's technical discipline is the ability to demonstrate a proven record both of first class personal research and effective research management preferably in a major engineering-based industry. Whilst it is desirable that this experience is relevant to the nuclear energy industry, this is not an exclusive requirement. These are challenging and important posts demanding high personal qualities and a significantly long period of relevant experience.

The salary for these appointments is in a range up to £13,600 p.a. (due for review as from 1 April 1979).

Applications giving details of qualifications, experience, publications etc. should be sent within two weeks to W. H. F. Brooks, Divisional Personnel Manager, Courtenay House, 18 Warwick Lane, London EC4P 4EB. Quote Ref. **NRD1.**

CENTRAL ELECTRICITY GENERATING BOARD
RESEARCH DIVISION

9681(A)

LINCOLN COLLEGE
(University College of Agriculture)
New Zealand
LECTURER IN CROP PHYSIOLOGY

Applications are invited for the position of Lecturer in the Department of Plant Science. Applicants should have qualifications and research experience in crop physiology, preferably combining a sound knowledge of physiological principles with experience of crop or pasture production. Teaching at undergraduate and postgraduate levels will necessitate competence in such topics as photosynthesis, water relations, competition etc.

Commencing salary according to qualifications and experience. Present salary scale is: NZ$11,529 to NZ$14,250. Travel and removal expenses are reimbursed up to specified limits. New Zealand Government Superannuation is available.

Initial enquiries may be made to the following now on study leave in England: Dr P. Jarvis, Plant Physiology Department, University of Sussex, or Dr W. R. Scott, Plant Breeding Institute, Cambridge.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on April 16, 1979. 9611(A)

POSTDOCTORAL POSITION

available immediately for research on membrane phenomena associated with mediator release in allergy. Applicants should have a background in immunochemistry or biochemistry. Send curriculum vitae and three letters of recommendation to Dr A. Froese, Department of Immunology, University of Manitoba, 730 William Avenue, Winnipeg, Manitoba, CANADA R3E OW3. 9648(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF BIOCHEMISTRY
RESEARCH ASSISTANT

Applications are invited from graduates in Biochemistry, or related subjects, to work on a project concerned with Neurotransmitter metabolism in brain cell cultures.

The project is funded by the Scottish Home and Health Department, and is under the supervision of Dr R. I. Freshney, Beatson Institute, Glasgow, and Dr P. F. T. Vaughan, Biochemistry Department, Glasgow University.

The position will be for two years at a starting salary of £3,634 rising to £3,883 (Range 1B, Research and Analogous Staff scales).

Applications, enclosing curriculum vitae and the names of two referees, should be sent to Dr P. F. T. Vaughan, Biochemistry Department, University of Glasgow, Glasgow G12 8QQ, by March 2, 1979.

In reply please quote Ref. No 4364M. 9624(A)

UNIVERSITY OF LEEDS
DEPARTMENT OF CARDIOVASCULAR STUDIES

Technician in Charge required to supervise cardiological physiological techniques. The post involves administration, quality control, training of staff, and co-ordination of routine diagnostic technical investigations in two hospitals, and requires an ability to control a large technical staff (30 plus technicians) and be responsible to hospital consultants. Experience in the techniques of cardiological investigation is essential. Prior enquiry to the department is encouraged. The level of qualification looked for is H.N.C. or equivalent together with substantial relevant experience.

Salary is on the scale £5,085 to £5,517 (Grade 8b).

Salaries are presently under review.

Applications to:

Professor R. J. Linden
Department of Cardiovascular Studies
New Medical School
University of Leeds
Leeds LS2 9JT. 9674(A)

Ph.D IMMUNOLOGIST/ IMMUNO-PHARMACOLOGIST

We have a vacancy for a research graduate in the Department of Biochemical Pharmacology at our R & D Laboratories situated in Leicestershire

Applicants should preferably be qualified in immunology or pharmacology with relevant research experience to Ph D level The successful applicant will join a team of biologists investigating cellular and animal models of rheumatoid arthritis

Fisons offer a competitive salary and assistance with relocation expenses where appropriate

PHARMACEUTICAL DIVISION

Southampton THE UNIVERSITY

DEPARTMENT OF PHYSICS

Applications are invited for two LECTURESHIPS in the Department of Physics The persons appointed will be expected to play a full part in the Department's programme of teaching and research in experimental physics It is likely that preference will be given to candidates with research experience in the fields of condensed matter physics, low-temperature physics and space physics

Salary scale £3,883 to £7,754 per annum plus U S S The initial salary will depend on qualifications and experience

Further particulars may be obtained from Mrs E C P Sears, Staffing Section The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than March 26, 1979 Please quote reference number 1703/A/Na 9470(A)

THE QUEEN'S UNIVERSITY OF BELFAST

RESEARCH SCIENTIST

DEPARTMENT OF MEDICINE

Applications are invited from graduates with an honours degree in biochemistry, physiology or biology, preferably postdoctoral, for a research programme into the role of gut and pancreatic hormones in diabetes mellitus. Facilities would be provided in the Department of Medicine, where multiple analytical, histological and chemical techniques are available The post is tenable for one year from April 1, 1979 or as soon as possible thereafter and may be renewed until January, 1982

Salary scale (under review) £3,885 to £5,130 with superannuation, initial placing depending on age, qualifications and experience

Curriculum vitae, giving the names and addresses of two referees, should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 INN, Northern Ireland Closing date March 5, 1979 9628(A)

KING'S COLLEGE HOSPITAL

DEPARTMENT OF CHILD HEALTH

RESEARCH ASSISTANT

A graduate research assistant with experience in standard biochemical enzymatic and immunological techniques is required to join an on-going study of Collagen metabolism in liver disease in infancy and childhood This is part of a larger project being undertaken jointly by the Department of Child Health and the Liver Unit at King's investigating factors which cause chronic liver diseases in this age group.

The objective of this study is to find means of controlling collagen deposition and thereby preventing permanent liver damage.

Pay will be according to qualifications and hours.

For application form and job description, please apply to the District Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS. Tel. 01-274 6222 ext 2254. Closing date; March 1, 1979 9602(A)

AUSTRALIAN NATIONAL UNIVERSITY

Research School of Physical Sciences

FELLOW/SENIOR FELLOW—LASER PHYSICS

DEPARTMENT OF ENGINEERING PHYSICS

Applications are invited for a post of Fellow/Senior Fellow in the Research School of Physical Sciences, to provide leadership for a research group in Laser Physics which is part of the Department of Engineering Physics. The research group currently has three other (non-tenured) members of academic staff and appropriate professional and technical supporting staff. It has a well established laboratory with two neodymium laser systems producing peak powers of up to a few hundred gigawatts. Research centres on the interaction of intense laser radiation with matter. Current main research areas are the spectroscopy of, and superthermal particle generation in, laser-produced plasmas, and non-linear forces in laser-matter interactions.

The appointee will have a strong background of experimental laser-based physics. In addition to carrying out his own research he will be expected to develop and coordinate research projects which fully utilise the group's facilities and joint expertise in ways suitable to a university research laboratory whose emphasis is on basic physical science, initiate and cooperate in research projects with others in the Research School, and collaborate as appropriate with other Australian laser groups

Appointment is for five years in the first instance with the possibility of extension, after review, to retiring age, 65 years

Closing date. March 16, 1979.

Salary will be in accordance with qualifications and experience within the ranges Senior Fellow $A24,686 to $A28,773 per annum, Fellow $A18,401 to $A24,652 per annum Current exchange rates $A1 · $US1 13 · 56p.

Reasonable appointment expenses are paid Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square London WC1H 0PF 9608(A)

QUEEN ELIZABETH COLLEGE

Kensington

(University of London)

LECTURER IN PHYSICS

Applications are invited for the post of Lecturer in Physics The Department, besides the traditional single-subject physics course, has undergraduate courses in medical physics and astrophysics Applicants should preferably have interests in teaching and research directed either towards the analysis and application of images formed by optical, radio or matter waves or the associated optoelectronic and solid state devices. Salary on scale £3,909 to £7,754 per annum, the starting salary depending on qualifications and experience. London allowance of £450 per annum is paid in addition.

Apply to the College Secretary, Queen Elizabeth College, Campden Hill Road, London W8 7AH from whom further particulars and an application form may be obtained.

9605(A)

AUSTRALIAN NATIONAL UNIVERSITY

CENTRE FOR RESOURCE AND ENVIRONMENTAL STUDIES

DIRECTOR

The University seeks to appoint a Head of the Centre for Resource and Environmental Studies to succeed Professor Frank Fenner, C M G , M B.E , F A A , F R S., who will retire at the end of 1979.

The Centre is designed to advance research in resource and environmental studies, to provide postgraduate training including a Master's degree by coursework, and to seek solutions to problems of resource and environmental management The present academic staff, including the Director, comprises five senior tenured staff and seven research fellows, drawn from both social and natural science disciplines.

The Director is responsible through the Vice-Chancellor to the University Council for the operation and development of the Centre and for its administration and financial management The Director's most important role is that of academic leadership, he will be expected to lead and coordinate multidisciplinary research studies within the Centre, taking a key role in developing the major projects that will at any time occupy a substantial part of the time of all staff of the Centre His professional background may be in any field appropriate to the Centre He should have a broad interest in and understanding of resource and environmental studies, and should if possible have had experience in leading multi-disciplinary team projects

The Director will also hold a Chair in the University The term of office as Director will be a matter for agreement with the University but is likely to be for five to seven years with the possibility of extension for a further period Appointment as professor is until retiring age, i e the end of the year in which the professor reaches the age of 65 years, with the option of retiring at any time after age 60.

Anyone interested in being considered for this appointment is asked to write in confidence to the Registrar, P O Box 4, Canberra, ACT 2600, Australia from whom further information may be obtained.

Reasonable appointment expenses are paid Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

9636(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of SENIOR LECTURER/LECTURER IN THE DEPARTMENT OF PHYSICS Applicants must have a Ph D or equivalent Applicants for Senior positions must have considerable University lecturing experience Preference will be given to persons interested in Solid State Physics and Nuclear Physics Appointee will be required to teach undergraduate courses leading to a B Sc in two subjects or in Physics Salary Scale: Senior Lecturer K7,608 to K8,016 per annum Lecturer K4,956 to K7,608 per annum (£1 sterling=K1 56) The British Government may supplement salary in range £2,922 to £4,350 per annum (sterling) for married appointee or £930 to £1,968 per annum (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages Family passages, baggage allowance, medical aid scheme; regular overseas leave Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University of Zambia, P O Box 2379, Lusaka, Zambia, by March 31, 1979. Applicants resident in the U K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address.

9635(A)

UNIVERSITY OF EXETER
LECTURER IN COMPUTING SCIENCE

Applications are invited for a lectureship in the Department of Computer Science, tenable from October 1, 1979

Candidates should be qualified persons working in any area of computer science Specialisations which are of particular interest, but which are not intended to make up an exhaustive list, are data-base computation and theory, artificial intelligence, computer architecture and systems, theory of programming languages and semantics, operating systems, distributed computing and networks.

Commencing calary will be within the range £3,883 to £4,631 per annum (under review) on the scale £3,883 to £7,754 per annum (under review) The post is subject to a probationary period not exceeding three years with the prospects of permanency thereafter

Further particulars may be obtained from Miss Doreen Watson, University of Exeter, Northcote House, Exeter EX4 4QJ, to whom applications (eight copies, overseas candidates one copy) should be forwarded by March 9, 1979 Please quote reference No 3205

9659(A)

ARMAGH OBSERVATORY
ARMAGH, N. IRELAND

Applications are invited
for the post of

RESEARCH ASSISTANT

The successful candidate will work in close cooperation with the Observatory staff on spectrophotometric programmes Candidates should preferably have a Master's degree in Physics or Astronomy, but a candidate with a good honours degree in the same subjects may be considered Some familiarity with modern techniques of data reduction by computer is highly desirable

Appointment is tenable for one year from October 1, 1979, but may be renewable Remuneration according to Range 1B for University Research Assistants

Applications stating qualifications and experience and names of two referees should be received not later than May 1 1979 by the Secretary, from whom further particulars may be obtained

9668(A)

JOHN INNES INSTITUTE NORWICH
HEAD OF VIRUS RESEARCH DEPARTMENT

Applications are invited for the above position

The Department is concerned with the biochemistry and biophysics of plant viruses, mycoplasmas and their constituents, the structure and composition of proteins, the composition and function of nucleic acids, and related topics. Work in similar fields is carried out in the other three departments and collobaration between departments is encouraged.

The facilities available in the Institute are comprehensive Teaching at undergraduate and postgraduate level may be undertaken. The Institute is modern and well situated Further particulars may be obtained from the Director, Professor Roy Markham, F R S.

The post is graded as Senior Principal Scientific Officer (£10,043 to £11,300) Non-contributory superannuation

Applicants should forward curriculum vitae, list of publications and names of suitable referees to the Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH, by March 31, 1979

9667(A)

THE UNIVERSITY OF NOTTINGHAM
LECTURESHIP

in the

DEPARTMENT OF THEORETICAL MECHANICS

Applications are invited for the above appointment Candidates should be qualified in a branch of mathematics which has some relevance to engineering, for example solid mechanics, fluid mechanics, electromagnetic theory, optimisation theory, numerical analysis, statistics, control theory or applied analysis

The duties of the post will include the teaching of mathematics to Engineering students and to Honours Degree level to students in mathematics-with-Engineering

The appointment will be made within the salary scale for University Lecturers, £3,883 to £7,754 per annum (interim scales) but the appointment will be made initially within the range £3,883 to £4,382 per annum

Further particulars and forms of application, returnable not later than March 2 1979, from the Staff Appointments Officer, University of Nottingham, University Park Nottingham NG7 614

9660(A)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF ENGINEERING
RESEARCH ASSOCIATE or ASSISTANT
for High Resolution Electron Microscopy

Applications are invited from persons who must have practical experience in both high-resolution electron microscopy and electronics, for an S R C-funded post with the Cambridge University 600 kV high-resolution electron microscope project.

The successful applicant will primarily be expected to assist external users in the operation of the microscope but will also be required to assist in the trouble-shooting and repair of a variety of electronic items and to construct simple electronic circuits Some standby/shift work may occasionally be necessary

Tenure 18 months from April 1, 1979

Pensionable salary in the range of £4 631 to £6,080 per annum, depending on age and experience

Applications (two copies), including a curriculum vitae, and the names of two referees should be sent to the Secretary, Faculty of Engineering, Cambridge University Engineering Department, Trumpington Street, Cambridge CB2 1PZ by February 28 1979

9666(A)

Head of Physical and Analytical Services Unit

The continuing expansion of the Medicinal Research Centre has led to the creation of a Physical and Analytical Services Unit, to undertake wide-ranging analytical and physico-chemical studies relating to our programmes in medicinal chemistry during all phases of research and development.

The Unit Head will be required to staff and equip this function and to contribute in the design of new Laboratories A staff of some twenty could ultimately be envisaged, encompassing spectroscopy, elemental microanalysis, chromatography and general analysis

Candidates should possess at least an appropriate first degree and have some years' relevant experience of analytical chemistry, preferably of pharmaceutical substances Considerable store will be placed upon a candidate's management potential and the ability to align the service closely to the needs of the research programmes through an outgoing and innovative approach

If you wish to be considered for this new post, please write, outlining your career to-date, to **John Atkinson,**

Site Personnel Manager,
Beecham Pharmaceuticals,
Medicinal Research Centre,

ANATOMIST
BROWN UNIVERSITY

invites applications
and nominations for a position as

INSTRUCTOR or ASSISTANT PROFESSOR

to teach human morphology and to conduct research in any area of morphological sciences. Applicants should have a doctoral degree and a demonstrated competence and enthusiasm for the teaching of the gross, functional anatomy of man in the perspective of his evolutionary and embryological development and in the focus of its clinical relevance Candidates with a productive research programme in comparative anatomy, primatology, embryology, neuroanatomy and other aspects of the morphology of whole organisms will be especially welcome Starting date July 1, 1979 Send before March 1, 1979, a curriculum vitae, description of teaching and research interests, and three letters of recommendation to Dr G E Erikson, Division of Biology and Medicine, Box G , Brown University, Providence, R I 02912 An Equal Opportunity/Affirmative Action Employer

9665(A)

ST THOMAS' HOSPITAL MEDICAL SCHOOL Academic Unit in Immunology Research Technician (MLSO/SMLSO) or Graduate Research Assistant Required from April 1979 for work on the Immunology of Blindness Experience in Cell/Tissue culture an advantage Usual salary scale (Whitley Council/University) according to qualifications/experience Applications quoting names of two referees to Dr D C Dumonde, Director, Academic Unit in Immunology The Rayne Institute, St Thomas' Hospital London SE1 7EH (Tel 01-929 9292 ext 3186)

9685(A)

UNIVERSITY OF EDINBURGH
LECTURER IN CLINICAL CHEMISTRY

Applications are invited from medical graduates and from science graduates holding an Honours Degree in Biochemistry or Chemistry or one of the related sciences, for the post of Lecturer in the Department of Clinical Chemistry which is situated in the Royal Infirmary of Edinburgh The department is responsible for providing a wide range of diagnostic services in clinical chemistry, is involved in teaching at several stages in the medical curriculum, and has good facilities for research and development The department is registered as a training laboratory for postgraduate professional qualifications. Arrangements can be made with Professor L G Whitby (031-229 2477, ext 2319) to visit the department

Salary on the scale £4,336 to £7,683 for a medically qualified Lecturer, or £3,883 to £7,754 for a non-medical Lecturer, and the successful applicant will be recommended for the award of an Honorary Contract by the Lothian Health Board.

Applications should be submitted by March 10, 1979, together with the names of two referees, to the Secretary of the University, Old College, South Bridge, Edinburgh EH8 9YL, from whom further particulars may be obtained Please quote Reference 1012.

9690(A)

FACULTY POSITIONS OPEN

College of Agriculture and Food Sciences
KING FAISAL UNIVERSITY
Hoffuf, Saudi Arabia

Inquiries invited from qualified applicants at all academic levels to teach courses in the following fields:

- Agricultural Economics
- Animal Science
- Animal Ecology
- Agronomy
- Agricultural Engineering
- Dairy Science
- Bee Keeping
- Horticulture
- Agricultural Extension
- Water Resources and Climatology
- Plant Pathology
- Home Economics and Nutrition
- Poultry Science

Prerequisites: Masters or equivalent degree; practical and/or teaching experience. Preference will be given to Arabic speakers.

Language of instruction is English.

Positions are available starting September 1979; interviews scheduled with the Dean in the United States and Great Britain during April/May 1979.

Salary Ranges

Rank	*Gross monthly salary in Saudi Riyals*	*Approx annual (sterling equivalent)*
Professor	SR 7,195 to SR 9,595	(£12,983 to £17,314)
Associate Professor	SR 6,435 to SR 8,185	(£11,612 to £14,770)
Assistant Professor	SR 5,245 to SR 7,765	(£9,466 to £14,012)
Lecturer	SR 3,280 to SR 4,530	(£5,919 to £8,174)

Benefits: Free furnished accommodations; substantial educational allowance for up to four children; air fare to and from Saudi Arabia once a year for husband, wife and two children plus 60-day paid summer holiday; no Saudi income tax.

Send complete curriculum vitae stating preference of course and names, addresses and telephone numbers of three references to:

Dr H. M. Elarosi, Dean
College of Agriculture and Food Sciences
King Faisal University

at the appropriate addresses below:

Post Office Box 2
Sunbury-on-Thames

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)
SOUTHERN DISTRICT (TEACHING)

GROUP DEPARTMENT OF HAEMATOLOGY

State registered M.L.S.O.
or
Junior B M.L.S.O.

Applications are invited for the above post from State-registered M.L.S.O's or graduates with a Science Degree which should include as a principle subject one or more of the following:— Biochemistry, biology, chemistry, microbiology, physics, physiology or zoology, or from persons who possess two science 'A' levels, preferably chemistry and biology.

This is a career post, commencing salary within the range of £2,370 and £3,015, depending on academic qualifications.

Applications stating age, qualifications (and the names and addresses of 2 referees to the District Personnel Officer, Floor B, Hallamshire Hospital, Glossop Road, Sheffield S10 SRX 9641(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF RADIOTHERAPY
(Cookridge Hospital)

RESEARCH TECHNICIAN

(Grade 3 £2,688 to £3,060)

Currently required to assist experimental studies of the effect of drugs on the chromosones of normal and cancer cells.

Suitable applicants will have formal qualifications and appropriate laboratory experience in the biological sciences Applications stating age, qualifications, experience and the names and addresses of 2 academic referees should be sent to Professor C A F Joslin, University Department of Radiotherapy, Regional Radiotherapy Centre, Cookridge Hospital Leeds LS16 6QB (Tel Leeds 673411 Ext 215) from whom further details may be obtained. 9673(A)

STUDENTSHIPS

UNIVERSITY OF WARWICK
POSTGRADUATE RESEARCH
in
ENVIRONMENTAL
MICROBIOLOGY

Applications are invited for research studentships in the Department of Environmental Sciences, tenable from October 1, 1979 leading towards a Ph.D. degree in the fields of cellulose degradation, stability of bacterial drug resistance factors, inorganic nitrogen metabolism in facultatively anaerobic thiobacilli and pseudomonads, bacterial oxidation and leading of metal sulphides by mesophilic and thermophilic iron bacteria, colonisation of antifouling surfaces by bacteria, soil quality and bacterial colonisation of soil particles, microbial polymers and soil aggregation, microbial dehalogenases, rhizosphere/root region microbiology Applicants should have or expect to gain this summer, a good honours degree in Microbiology, Biochemistry or a related subject. Enquiries to Dr J H. Slater, Department of Environmental Sciences, University of Warwick, Coventry CV4 7AL 9625(F)

AGRICULTURAL
RESEARCH COUNCIL
LETCOMBE LABORATORY
A.R.C. RESEARCH
STUDENTSHIP

APPLICATIONS are invited for an A R C Research Studentship tenable for three years from October 1, 1979 at the Letcombe Laboratory for research on the effect of soil conditions on root growth and crop yield

The student will work on the effects on cereals of either water shortage or waterlogging

Applicants must have, or be likely to obtain, at least Upper Second Class Honours and will be expected to register for a higher degree

Further details and application forms from the Secretary, Agricultural Research Council, Letcombe Laboratory, Wantage, Oxon, OX12 9JT Closing date for applications March 12, 1979 9672(F)

UNIVERSITY OF ABERDEEN
FACULTY OF MEDICINE
RESEARCH STUDENTSHIPS

Applications are invited from recent first or upper second class honours graduates in a biological science subjects, and from those who expect so to graduate in 1979, for research studentships established by the Faculty of Medicine from its Medical Endowment funds Successful applicants will study for the degree of Ph D on an approved project in one of the departments of anatomy, bacteriology, biochemistry, bio-med physics and bioengineering, developmental biology, pathology, pharmacology or physiology commencing in October 1979

The value of the studentship is £1,610 p.a. (for students living away from home) with payment of tuition fees and other allowances

Application forms and further particulars of the projects may be obtained from D. K Yule, University Office, Regent Walk, Aberdeen AB9 1FX, to whom applications should be submitted by March 16, 1979.

9702(F)

ROTHAMSTED
EXPERIMENTAL STATION
Harpenden Herts AL5 2JQ
PHYSICS IN AGRICULTURE
A.R C. Research Studentship
from October 1979

Applications are invited from graduates or expected graduates in physical science for an A.R.C Research Studentship The projects would include aspects of soil water physics and water movement in plants, with reference to the movement and availability of water in agricultural soils.

A first or upper-second class honours degree or an equivalent qualification is required The successful candidate will be registered with a University for a Ph D

Applications, giving the names of two referees should be sent by March 12 to Dr W Day, Physics Department, from whom further particulars may be obtained. 9645(F)

EAST MALLING
RESEARCH STATION
AGRICULTURAL
RESEARCH COUNCIL
STUDENTSHIP

Postgraduate studentship tenable from October 1, 1979, for 3 years for research leading to higher degree on one of the following projects

Water and mineral uptake by secondary thickened tree roots,

or

Integrated control, ecological effects of pesticides on the hop-damson aphid and its natural enemies

First or Upper-second Honours degree essential.

Further details and application form from the Assistant to the Secretary, East Malling Research Station, Maidstone, Kent, ME19 6BJ 9680(F)

SYMPOSIA

FIFTH EMBO ANNUAL SYMPOSIUM NUCLEIC ACID-PROTEIN INTERACTIONS

October 12–15 inclusive

EMBL Heidelberg

In addition to members of the Organising Committee invited speakers include:

J. Abelson (La Jolla); T. Bickle (Basel); H. Bujard (Heidelberg), P. Chambon (Strasbourg); R. Flavell (Amsterdam); C. Guthrie (San Francisco), S. Harrison (Harvard); C. Helene (Orléans), H. Hoffmann-Berling (Heidelberg); A. Landy (Brown); A. McPherson (Pennsylvania); M. Ptashne (Harvard); M. T. Record (Madison); H. Saedler (Freiburg); A. Schmitz (Geneva), J. Sperling (Rehovot), G. Stöffler (Berlin); F. W. Studier (Brookhaven); E. Vinuela (Madrid); J. C. Wang (Harvard), W. Wintermeyer (Munich); C. Yanofsky (Stanford).

The eight Plenary Sessions will cover Model Systems, Viruses; Chromatin; Polymerases; Regulatory Signals on DNA; Cleaving, Processing and Modifying Nucleic Acids; Ribosomes and tRNA; New Frontiers.

The Symposium will be held at the European Molecular Biology Laboratory Heidelberg with registration on Thursday, October 11. Plenary sessions will be held in the mornings and afternoons of October 12-15 inclusive. The Symposium banquet will be held on the evening of October 15. Poster sessions will be arranged; applicants wishing to present a poster should submit a title and an abstract of 1-2 pages. Participants will be accommodated in two hotels on downtown Heidelberg, and transportation to the meeting will be arranged.

The registration fee is DM 80.00 and includes daily lunches and the banquet but neither hotel charges nor evening meals.

Applications including a curriculum vitae should be sent to Dr. J. Tooze, Executive Secretary, European Molecular Biology Organisation, Postfach 1022.40, 69 Heidelberg 1, FRG, by May 31, 1979. Since the number of participants is limited to 200 the Organising Committee will notify those who have been accepted in August.

Organising Committee: D. Crothers (Yale); J.-P. Ebel (Strasbourg); A. Klug (Cambridge); C. Kurland (Uppsala, Chairman); J. Miller (Geneva); H. Schaller (Heidelberg); J. Tooze (Heidelberg, Secretary); C. Weissmann (Zürich). 9616(M)

STRAW DECAY SYMPOSIUM

April 10, 11, 1979

HATFIELD POLYTECHNIC
HATFIELD

Topics. Effects of straw residues on germination pathogens, fauna Decay on or in soil, mushroom composts, rumen. Improvement for animal feed, anaerobic digestors, Microbiological and Biochemical aspects.

SYMPOSIUM ON CELL ELECTROPHORESIS

A residential Symposium on "Cell Electrophoresis: Techniques and Clinical Applications" will be held in Bristol, U.K., from June 12-15, 1979.

It is intended that approximately 70 participants will be involved in the six half-day sessions, to be chaired by specialists in the topics covered Chairmen include:- Dr J Kaplan, Dr E Uzgiris, Professor E J. Field, Dr S Hanjan, Dr J Dickinson.

Laser-Doppler spectroscopy will be demonstrated, and Dr Unger of Zeiss will be introducing the Parmoquant

Short communications (10 mins oral, or poster display) are invited A Registration Fee of £10 will be charged

Further details may be obtained from Dr A W Preece, Oncology Research Unit, Radiotherapy Centre, Bristol BS2 8ED (Tel 0272 22041 extn 2469), or from Dr D Sabolovic, I N.S E R M, Unité de Cancérologie Expérimentale et de Radiobiologie, Vandoeuvre-lès-Nancy, France 54500 (Tel 83 55.52 01) 9675(M)

FELLOWSHIPS

BRITISH DIABETIC ASSOCIATION LAWRENCE RESEARCH FELLOWSHIP

SUBJECT: DIABETES MELLITUS

ELIGIBILITY. Open only to UK residents Candidates must be appropriately qualified in medicine or science. VALUE. Appropriate point on NHS or university scale up to registrar (or equivalent university) grade. TENABLE In any approved Institution in U.K, for 2 years OTHER INFORMATION· Awarded for independent research. NUMBER. Two offered, normally every two years (Offered for 1979/80). PARTICULARS: Available from Secretary-General, British Diabetic Association, 10 Queen Anne Street, London W1M 0BD Tel - 01-323 1531

CLOSING DATE. April 18, 1979. 9664(E)

UNIVERSITY COLLEGE DUBLIN

POSTDOCTORAL FELLOWSHIP IN PHYSICS

A postdoctoral fellowship is immediately available for research in the spectroscopy, both emission and absorption, of laser-produced plasmas Applicants should have experience of atomic spectroscopy, preferably in the vacuum ultraviolet region Some knowledge of laser-systems and/or plasma physics would also be desirable The appointment, which is supported by the National Board of Science and Technology will carry an initial salary of £3,762 (for a newly qualified Ph.D) and may be extended to three years Applications, accompanied by a curriculum vitae and the names of two referees, should be sent to

Professor P K. Carroll,
Department of Physics,
University College,
Dublin 4, Ireland 9620(E)

QUEEN MARY COLLEGE

University of London
PHYSICS DEPARTMENT
Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

for 3 years from October 1, for theoretical investigations on models of hadronic interactions on models of structure as part of an S R C. funded project led by Professor J M Charap. Initial salary in range £4,359 to £4,858 per annum (under review). Another Fellowship may be available for a theorist to work in the theory group on research not necessarily tied to this project. Further details available from Professor Charap, which applications including list of publications, curriculum vitae and names of at least two referees should be sent to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS Overseas applicants are asked to request their referees to write directly to Professor Charap 9640(E)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)
DEPARTMENT OF
BIOCHEMISTRY AND
CHEMISTRY
Applications are invited for two:

POSTDOCTORAL RESEARCH FELLOWSHIPS

in BIOCHEMICAL ENDOCRINOLOGY, supported by the Cancer Research Campaign and The Wellcome Trust, to work with Dr B. A. Cooke on the hormonal control of normal and neoplastic Leydig cells. Experience of cell culture and hormone receptors would be an advantage.

Commencing salary within range £3,909 to £4,655 plus £450 London Allowance.

Further information from the School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP to whom applications should be submitted as soon as possible, quoting reference CRC7W 9634(E)

POSTDOCTORAL FELLOWSHIP

Available from April 1, 1979 for a Ph.D. Graduate in biochemistry, virology, or related area interested in studying the structure and replication of mammalian and avian R.N.A viruses Applicants must have received the Ph D. degree no earlier than April 1, 1978. Salary is $12,000 for the first year and $13,350 for the second.

Send curriculum vitae and references to Dr D. G. Scraba, Department of Biochemistry, University of Alberta, Edmonton, Alberta T6G 2H7, Canada.

The University of Alberta is an equal opportunity employer 9378(E)

FELLOWSHIPS—continued

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF GENETICS
RESEARCH FELLOW (1A)
for five years
RESEARCH ASSOCIATE (1B)
for two years

Applications are invited for the above positions, tenable from May 1, 1979. Successful applicants will collaborate in a programme supported by the M.R.C. and S.R.C to extend and apply the methods of quantitative genetics to the analysis of human variation with particular reference to human behaviour. Applicants should be graduates in the biological or behavioural sciences and in the case of the Research Fellowship should have proven ability in research. Experience in any of the following areas would be advantageous: quantitative genetics, behavioural measurement, computer programming, statistics, the collection of human data.

Salary on the scale £3,883 to £6,555 (Research Fellow) or £3,884 to £4,882 (Research Associate) plus superannuation, maximum starting salaries respectively £5,842 and £3,883.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies), including full curriculum vitae and naming three referees should be sent by Friday, March 9, 1979 Please quote ref NL4 9626(E)

UNIVERSITY OF KENT AT CANTERBURY
POSTDOCTORAL FELLOWSHIPS IN CHEMISTRY

Applications are invited for two POSTDOCTORAL RESEARCH FELLOWSHIPS supported by the Science Research Council to work on the preparation and characterisation of carbonyl clusters. One post will be concerned with

$^{13}C-\{^{103}Rh\}$NMR measurements

of rhodium clusters (with Dr B. T Heaton). The other post will be concerned with X-ray structural determinations of carbonyl clusters in solution (with Dr B T Heaton and Dr A D C. Towl). Both posts are available for two years commencing October 1979. Salary in the range £3,883 to £4,382.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom completed applications should be returned by March 16, 1979. Please quote ref. A3/79

9612(E)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF MOLECULAR BIOLOGY
POSTDOCTORAL FELLOWSHIP

available for work on the molecular biology and genetics of the cell cycle of Escherichia coli. The position, which is available immediately, is currently supported until December 1980 but there is the possibility of extension beyond that date. Candidates should be in a position to take up the appointment between now and the autumn of 1979.

Apply to Dr W D Donachie, Department of Molecular Biology, University of Edinburgh, King's Buildings, Mayfield Road, Edinburgh, EH9 3JR Scotland Please quote Reference 5005

9630(E)

COURSES

ilea INNER LONDON EDUCATION AUTHORITY

Would you like to teach science in an Inner London Secondary School?

Applications are invited from graduates in pure or applied science or engineering, who are at least twenty-five years of age, and who wish to be allotted a place on the Authority's one-year science induction course. This will be held at Avery Hill College of Education, beginning in September 1979, and those who successfully complete it will be awarded the post-graduate certificate of education.

Successful applicants will hold a one-year temporary teaching appointment during the period of the course, and will be paid the appropriate salary as a qualified teacher. On successful completion of the course they are guaranteed a permanent position in the Authority's general teaching service, and will be expected to remain with the Authority as full-time secondary science teachers for at least two further years.

Preference will be given to those with degrees in the physical sciences or in engineering. However, graduates in the biological sciences are also urged to apply. Provided they are willing to undertake a measure of retraining during the course, sufficient to equip them to teach physics or chemistry to 'O' level, their applications will be given very careful consideration.

Previous experience in other fields will be taken into account when assessing starting salaries, currently within the range £3438 to £5136 including London allowance. Starting salaries can therefore be substantially above the minimum of this scale – which, in any case, is currently the subject of salary negotiations.

For application forms and further information write now to the Education Officer, EO/TS2, Room 67, The County Hall, London, SE1 7PB, or telephone Mrs Marchant on 01-633 2051. Closing date is two weeks from date of publication.

9698(D)

BRITISH COUNCIL COURSE

Agricultural Education and Training

September 2-14, 1979

The aim of this course is to review and discuss the developments which have taken place in the last ten years in Britain in the education and training provision for agriculture resulting in new curricula designed to meet the needs of operatives, craftsmen and technicians. The course is mainly intended for senior agricultural and horticultural educationists, senior staff and inspectors actively involved in vocational agricultural and horticultural education and training working outside Britain

Fee including full residence £365

Further details and application forms may be obtained from local Representatives of British Council offices overseas or from The Director, The British Council 65 Davies Street, London W1Y 2AA 9651(D)

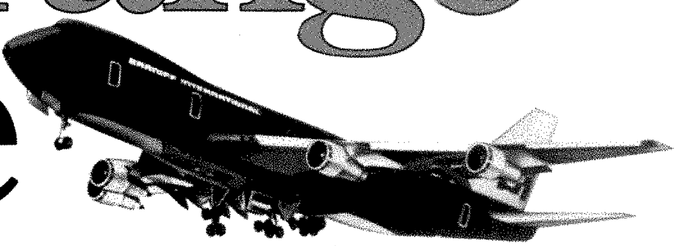
Ride the Big Orange to the Big Country.



The only daily 747 non-stop to Dallas-Fort Worth and South-Western U.S.A.

No other airline comes within sight of it. The *only* 747 non-stop daily service to America's South-west from Britain, the *only* non-stop service from London Gatwick to Dallas-Fort Worth.

THE DALLAS-FORT WORTH GATEWAY

Dallas-Fort Worth is the newest and most convenient gateway to America's Big Country.

And from there Braniff has more than 150 flights daily to some 40 cities throughout the Southwest, Far West and mid-America. And Mexico.

For example:

Leave	London Gatwick	11.45am
Arrive	Dallas-Fort Worth	3.05pm
	Houston	4.50pm
	Las Vegas	4.48pm
	San Antonio	4.47pm
	Oklahoma City	5.00pm
	Tulsa	5.10pm
	Denver	5.30pm
	Kansas City	6.40pm
	Mexico City	9.15pm
Leave	Dallas-Fort Worth	6.45pm
Arrive	London Gatwick	9.15am

There is a helicopter link, or a ground link, free to Braniff passengers flying into Heathrow en route to Gatwick for the Braniff flight.

FARES

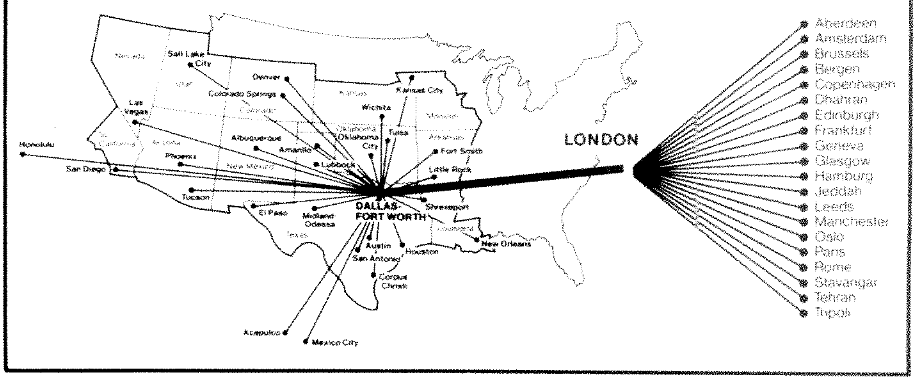
There is a wide range of fares, including First Class, Economy, Advanced Purchase Excursion, Budget and Stand-by. To Dallas-Fort Worth there are no lower fares than Braniff's.

RESERVATION SERVICE

For flight schedules and reservations (including seat assignment) call your travel agent or the Braniff reservations centre in London **01-491 4631.**

In these cities Dial 100 and ask Operator for Freefone 2276.

Aberdeen Birmingham Edinburgh Glasgow Liverpool Manchester Sheffield.



BRANIFF INTERNATIONAL

Mainland USA, Hawaii, Mexico, Alaska, Canada, South America and Europe.

IMMUNOCHEMICALS FROM MILES?

YES, INNOVATIVE AND PROVEN PRODUCTS FOR RESEARCH AND CLINICAL LABORATORY USE.

Perhaps you think of Miles as a place to get the unusual, like antiserum to rat IgE or equine IgM.

Perhaps you know we offer a wide selection of human protein antisera encompassing newer products, such as antisera to myoglobin, ferritin and β-2 microglobulin, as well as established antisera to immunoglobulins, α-1 antitrypsin and other major serum proteins.

Of course, you may not associate us with immunochemicals at all... We think you should.

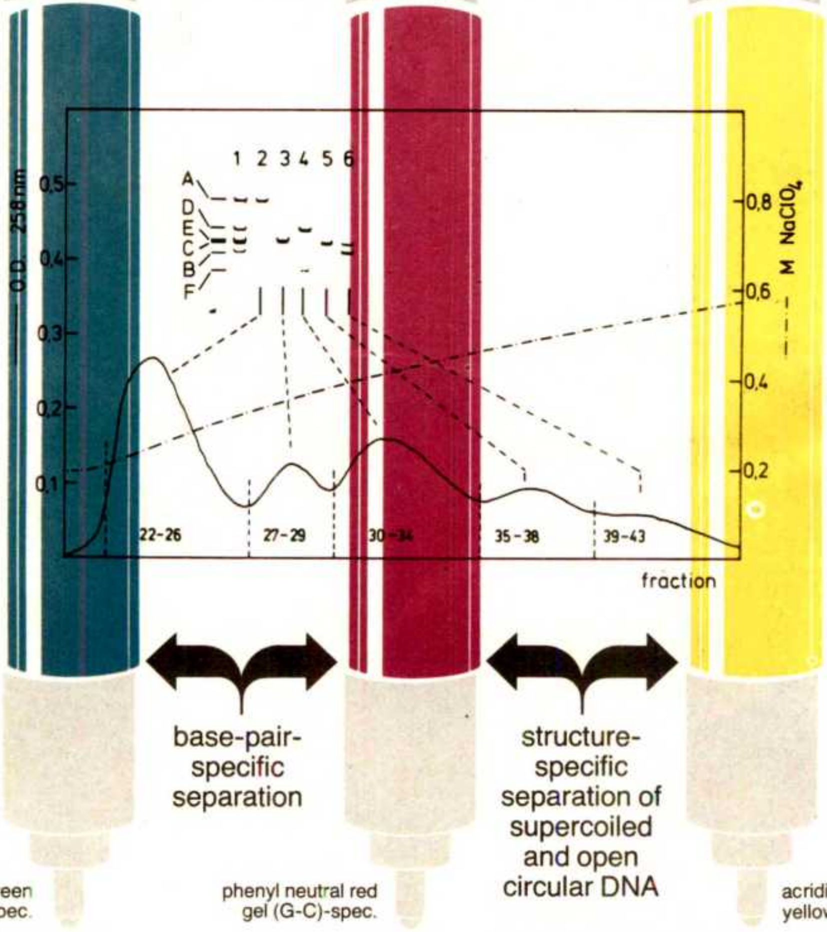
For the separation of DNA

use now the Boehringer Mannheim affinity adsorbents for the base-pair -or structure-specific affinity chromatography



The elution profile for a separation of 0.5mg of λ-DNA digested by Eco RI on a malachite green-substituted column (1.5 × 16cm, 5.8ml/h flow rate, room temperature).

Bünemann, H. & Müller, W. (1978) Nucl. Acids Res. **5**, 1059–1074.

DNA affinity adsorbent, (A-T)-specific
(malachite green gel), 25 ml, Cat. No. 275352
DNA affinity adsorbent, (G-C)-specific
(phenyl neutral red gel), 25 ml, Cat. No. 275387
DNA affinity adsorbent, structure-specific
(acridine yellow gel), 25 ml, Cat. No. 302376

For checking the separation method we recommend

DNA-molecular weight marker I
(λ-DNA + Eco RI) Cat. No. 236233
DNA-molecular weight marker II
(λ-DNA + Hind III) Cat. No. 236250
or Lambda-DNA, Cat. No. 208396
together with our restriction endonucleases.

New from Mettler: Two phototitration instruments

The new DK18 and DK19 Phototitrators function according to a dual beam measuring principle built into the immersion probe. The measuring light beam travels through the sample solution without having to be specially shielded. Neither daylight nor artificial lighting can affect the measuring results because the high-frequency light modulation of the instrument serves to suppress the interference effects caused by external light sources.
The main difference between the two instruments consists in the type of their interference filters. The DK18 is equipped with a continuous scanning filter which also makes possible the recording of spectra. The DK19, on the other hand, uses interchangeable plug-in filters with fixed wave lengths. And the measuring range of both instruments goes from 400 to 690 nm (visible range).
These two new phototitrators from Mettler open up a broad spectrum of new possibilities.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Pharmalyte™, the new ampholyte

Pharmalyte is part of a new integrated system for flat bed isoelectric focusing, electrophoresis and immunoelectrophoresis. Find out more about Pharmalyte and the Pharmacia Flat Bed System – today!

Pharmalyte gives you:
  Convenient and stable gradient intervals without mixing
  More resolution. Over 1000 high buffering capacity ampholytes per pH interval
  Less risk of local "hot-spots" and overheating because the conductivity is even across the whole gradient
  Easier recovery of proteins. Pharmalyte doesn't contain high molecular weight contaminants.

Pharmalyte is a series of new and unique carrier ampholytes developed entirely within the research laboratories of Pharmacia Fine Chemicals to give you superior resolution in isoelectric focusing.

Industrial innovation in the UK—a first step

Over the past few years, Britain's faltering industry has come in for much attention from a variety of official and semi-official bodies. There has been the establishment of a National Enterprise Board and several discussion documents on the engineer and his relation with universities, industry and government, culminating in the Finniston Committee of Enquiry. The Science Research Council has taken a new range of initiatives such as the Co-operative Awards in Science and Engineering scheme, Total Technology courses and Teaching Companies. Now from the very centre of government, the Cabinet Office, comes a paper *Industrial Innovation* (HMSO, £1) produced by an unnamed working party, chaired by Dr A. Spinks (ICI), for the Advisory Council for Applied Research and Development (ACARD). The working party had a brief to consider ways in which conditions for innovation in British industry might be improved and to make appropriate recommendations for Ministerial action.

'Innovation', in current usage, means much more than just invention. It encompasses improvements to present products and processes as well as the introduction of new ones, and innovation does not just comprise what goes on in the R & D laboratory; it includes all the activity that goes into getting the new or improved commodity widely accepted. Some relatively unspectacular activities such as making car doors that shut with a satisfying click, or mechanical devices that break down less frequently than their competitors may be much more profitably innovative than no end of ultra-high technology. Identifying niches that no-one else has explored, be they relatively humble in technological terms, may bring major rewards. Maybe a slower but much cheaper propellor plane would be a better project for the 1980s than another supersonic jet transport.

It is not only Britain that is seriously worried about its industry's record. The United States is equally concerned about overseas competition from Japan and Western Europe, even with the built-in help of an enormous and affluent domestic market, many US industries are finding themselves being undermined. At present an enormous nationwide effort is in train to come up with some policy options for President Carter. By contrast the British document a mere 26 pages in length looks slim indeed, and sensible as many of the suggestions are, they sadly lack the sort of detailed analysis, case studies and reference to give the paper the weight which will impress ministers and their advisers.

The report lists, as obstacles to innovation in Britain, continual changes in the economic environment, lack of incentives for managers and entrepreneurs, the burden of legislation, overmanning, falling industrial productivity, emphasis on short term returns, lack of qualified manpower and technological ignorance in board rooms. The working party, in response to this, recommends a variety of corrective actions—a tax structure more favourable to investment and to small businesses, more encouragement to Research Associations, strengthening university/industry relationships, pressure on nationalised industries and government procurement agencies to support their suppliers, notably small technologically based industries, and so on.

Few would argue either with the analysis, brief as it is, or that the measures suggested were inappropriate, but even so the working party has concentrated its attention heavily on tactics, rather than on strategy. We urgently need to know the answer to questions such as what sort of industrialised nation does Britain wish to become; whether it will incorporate into an industrial policy any considerations of technological interaction with the developing world; whether our present educational system, at secondary as well as at tertiary levels, does enough to make students aware of the importance of less-glamorous industry to our survival as a trading nation; whether there are important environmental, 'public-interest' and health-and-safety issues which ought to be raised in any discussion on industrial improvement; whether there is a 'rational' level at which Britain should spend on R & D.

ACARD have made a useful modest step forward in confronting the question of industrial innovation. It is to be hoped that they will not regard the job as finished. ☐

Science has a word for it: We recently asked for examples of words or phrases from the world of science that could be given a much wider currency. Some outrageous examples were received of the misuse of words: from Stonybrook came a memorandum describing the university as a 'multi-ethnic and bi-sexual community'; from NASA came 'inhibit time advance' as an instruction to stop a computer programme, and 'versatilify'. But the prize of £10 goes to Donald Higby, of Roswell Park Memorial Institute, Buffalo, for a string of terms from cancer medicine including 'metastasize' as in 'I will have to metastasize to the conference' and 'dose-limiting toxicity' in 'I've reached the dose-limiting toxicity in my relation with Dr X'.

Italian Commission covered up Séveso delays

Italy's official report on the Séveso accident leaves out some important information, writes **Alastair Hay**

THE 412 page Italian Parliamentary Commission Report on the accident at Séveso in Italy in July 1976—an accident in which tetrachlorodibenzodioxin (dioxin) from ICMESA's trichlorophenol reactor was discharged over a populated area—should have been the definitive report on the episode. But documents in *Nature's* possession indicate that the claims of Givaudan—a subsidiary of F. Hoffmann la Roche and the owner of the reactor—are more accurate than those of the commission's report.

The bitter and continuing disagreement centres on the sequence of events between 10 July 1976, when the Séveso accident occurred and 24 july when evacuation of the dioxin-contaminated area was ordered. Givaudan claims that it was responsible for urging the authorities to evacuate the area. But the commission's report assigns a far more important role to Italian scientists in recognising the danger. Another report however, that of the Lombardy Regional Government supports Givaudan's claims and indicates that the Italian Parliamentary Commission omitted some vital evidence in its report.

Few would disagree that the two-week delay in ordering the evacuation of residents may have had serious consequences for health. The Italian authorities claim that the delay was the result of a lack of information on the extent of the dioxin contamination. According to the Parliamentary Commission report it was not until the evening of 23/24 July that "positive evidence of the presence" of dioxin was obtained from the results of analyses performed by the Italian laboratories—the Superior Health Institute in Rome and the Provincial Laboratory of Hygiene and Prophylaxis (PLHP) in Milan.

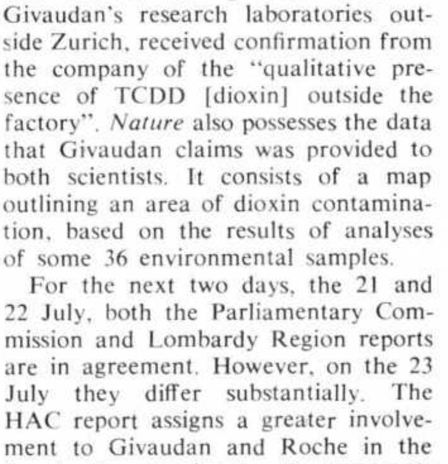
The full version of the commission's report—only recently made available to interested parties—differs substantially from the summary made available to the press by the Italian authorities when the report was presented to the Italian Parliament in June 1978. The press version implies that the Italian laboratories found dioxin and that their results were used as the basis for ordering the evacuation.

The account in the full report, however, says that two Italian scientists, Drs Ghetti and Cavalloro, flew to Givaudan's laboratory at Dubendorf, near Zurich on 19 July and there received confirmation that dioxin had been discharged into the atmosphere at Séveso. They immediately returned to Italy and duly informed the various authorities. Meetings were held in the days following, and arrangements made for monitoring the situation. It was not until a meeting on 24 July, under the chairmanship of the Health Assessor Dr Rivolta, that the evacuation was ordered. The Italian laboratory results were presented at the meeting, says the report, and confirmed by the Givaudan representative, Dr Vaterlaus.

However, neither the commission nor the press release versions are supported by official reports of the Health Assessor's Council (HAC) of the Regional Board of the Lombardy Region. One controversial issue is the question of whether the ICMESA management notified the appropriate authorities about the accident and its potential seriousness on 10 July. The main HAC report says that it did. All reports confirm that it was the 15 July when the first order was posted by the local mayor to warn the population about the contamination and banning the "consumption of fruit and vegetable products" grown in the vicinity of the factory.

On 18 July, says the HAC report Dr Cavalloro, Director of the PLHP in Milan, suspected the presence of dioxin in the discharge from the reactor. His suspicion was confirmed by ICMESA although the parent company, Givaudan, says the report, "does not admit that there is dioxin; it allows this to be understood". Under the entry for 20 July, the HAC report says that on the previous evening Drs Cavalloro and Ghetti, during their visit to Givaudan's research laboratories outside Zurich, received confirmation from the company of the "qualitative presence of TCDD [dioxin] outside the factory". *Nature* also possesses the data that Givaudan claims was provided to both scientists. It consists of a map outlining an area of dioxin contamination, based on the results of analyses of some 36 environmental samples.

For the next two days, the 21 and 22 July, both the Parliamentary Commission and Lombardy Region reports are in agreement. However, on the 23 July they differ substantially. The HAC report assigns a greater involvement to Givaudan and Roche in the Lombardy Regional Government's deliberations than does the commission's report. It says that on 23 July a representative of Roche arrived at an extraordinary meeting of the Provincial Health Council in Milan where various Italian scientists with an interest in Séveso were considering



Child exposed to dioxin

0028-0836/79/0277—0588$01.00

the measures to be adopted and was forbidden to speak. Later that day at another meeting—of the local administrators of the Séveso region—the representative, Dr Guiseppi Reggiani, Director of Clinical Research for Roche, stressed to the Health Asessor, Dr Rivolta, the necessity and urgency of evacuating the population at Séveso exposed to the highest concentrations of dioxin. Rivolta asked him to put his concern in writing. The report says that this request was complied with on 24 July in a letter (signed by Givaudan's president, Dr Guy Waldwogel) At the same time, the report adds, a map of the polluted area was handed over, with the first quantitative data on the pollution released by Givaudan. The map contained the results of analyses of 44 environmental samples The Lombardy Region report suggests therefore, that Givaudan and Roche played a far larger role in documenting the pollution at Séveso than the Parliamentary Commission gives them credit for.

On the 19 July however, Givaudan claims that the two Italian scientists Ghetti and Cavalloro, who visited the company's laboratory near Zurich, received most of this data—albeit from some 36 environmental samples. If this is true why does the Parliamentary Commission report not mention it? (*Nature* has ascertained that this information was presented to the commission during a six hour meeting) and why had the Italian authorities not even considered an evacuation by 23 July when they knew of the dioxin contamination on 20 July?

The Parliamentary Commission report admits that the laboratory facilities and expertise required to assess dioxin contamination at Séveso were not available in Italy. This is one reason why Ghetti and Cavalloro were provided with the necessary dioxin standards when they visited Givaudan on 19 July. Dr Cavalloro declined to tell *Nature* the number of measurements his laboratory had made between 20 July and 11.00 p.m. on 23 July. Asked about the differences between the reports of the Parliamentary Commission and Lombardy Region he felt he was not competent to answer and that as it was a political question it should be directed to the Lombardy Regional Government. He and his colleagues, he said, were "only technicians".

Signor Cesare Golfari, President of the Lombardy Regional Government told *Nature* that he thought the Parliamentary Commission Report was "good for the Regional Government". In his opinion, it gave an adequate account of events at Séveso. Roche, too, welcomes the overall objectivity of the commission's report—the commission was eqaully scathing of Roche, Givaudan and many of the Italian authorities. A spokesman for Roche, however, described the commission's report as telling a "twisted tale". He said that he "certainly" knew that the commission's charge that Givaudan had not informed its workers at ICMESA about the hazards of dioxin was true. He also said that all but 6 or 8 of some 6,000 civil claims for damages against Roche had been settled and conceded that the lawyers had recommended prompt settlement of claims to avoid a higher bill if the criminal court case went against the company.

The criminal prosecution is in the hands of the Italian Judiciary. The court will consider whether or not Givaudan was negligent in its maintenance of the trichlorophenol reactor at Séveso, and whether it could have informed people more quickly after the accident of the danger they faced. The hearing is unlikely to take place for some time however, for the judge originally appointed to deal with the case has recently been promoted and his successor will need some time to familiarise himself with the background to the case.

Until the court hearings are available, the Parliamentary Commission report will remain the most comprehensive appraisal of the accident at Séveso. Britain's Health and Safety Executive (HSE), is to have the document translated. When that is available much of what happened at Séveso will be available for public scrutiny outside Italy. ☐

Genetic manipulation: Britain may exempt "self-cloning"

Britain's Genetic Manipulation Advisory Group will meet this week to reconsider issues which have been bothering the group for some time—particularly the definition of genetic manipulation and whether it should include "self-cloning" experiments.

These are experiments in which the genes of a bacterium are cloned within the bacterium itself—such as *E. coli* within *E. coli*—which are already exempted from control under the revised US National Institutes of Health guidelines.

GMAG has been under considerable pressure from bacteriologists—and lately the Royal Society (see *Nature*, 15 February, page 509)—to relax its control of such experiments, which form a substantial proportion of potential recombinant DNA research; and now it appears to be responding. Even if GMAG decides in favour of a strict definition of recombinant DNA experiments which includes self-cloning, it is felt that it will move to exempt the experiments from categorisation.

At its last meeting GMAG decided "in principle" to adopt the new risk assessment scheme devised by Sydney Brenner—but only for a trial period of about one year. Four proposals for experiments have already been received for consideration by risk assessment, including one application for downgrading, and two have already been assessed. In these cases the categorisation was the same as it would have been under the phylogenetic Williams guidelines, so there was no conflict, but members of GMAG are known to be worried about cases where there is disagreement. It is felt that much is yet to be learned about real risk factors, and that much more research on them needs to be undertaken before risk assessment can be firmly established.

Meanwhile the "technical panel"—which will make the assessments and advise the Medical Research Council and Health and Safety Executive on risk research that needs to be undertaken—is being established under the chairmanship of Professor Peter Walker of the University of Edinburgh, a man who has been not uncritical of excessive control of recombinant DNA research.

The technical panel will have some nine "core" members, including representatives of GMAG and outside experts, and will also co-opt special expertise when necessary.

This week's meeting of GMAG will be a particularly interesting one for it may be the first at which the deeper views of its seven new members (out of a total of 19) will be tested. The last meeting was concerned with a detailed discussion of the risk assessment scheme, and like many of the regular GMAG meetings it failed to address—or at least reach decisions on—certain matters of principle such as the basic definition of its area of competence. Hence this week's extraordinary meeting, called specifically to address these questions.

If the meeting reaches its conclusions rapidly, GMAG will publish a short document for researchers outlining its new policy. A full note will be issued in due course.

Robert Walgate

MPs accuse health officials of unconcern over risks and benefits of DNA research

BRITISH members of Parliament last week accused officials of the Department of Health and Social Security of displaying an "active disinterest" (*sic*) in the possible health risks of research involving the use of recombinant DNA techniques.

In particular, the MPs expressed concern that a non-specialist assessor who sits on the Genetic Manipulation Advisory Group on behalf of the DHSS should represent the UK on an ad hoc group of experts which has drawn up a draft directive on the regulation of genetic manipulation experiments for the European Economic Commission.

These concerns were voiced at a meeting last week of a subcommittee of the House of Common Select Committee on Science and Technology which is currently holding a series of public meetings on genetic engineering in the UK.

Mr C. M. Regan, under-secretary responsible for public and environmental health at the DHSS, told the MPs that because recombinant DNA techniques essentially involved research processes, their safety was a matter for the Department of Education and Science and the Health and Safety Executive rather than DHSS. Although DHSS had an assessor on GMAG, the public health aspects of possible hazards was therefore "not a matter which falls to us directly".

The MPs accused the DHSS officials of taking an unimaginative approach, both to their responsibilities for protecting the public from unpredictable hazards of the research, and to the possibilities that the research promised for the production of drugs such as insulin.

Mr Ted Leadbitter, who had last week accused DES officials of using "under-secretary language" in giving evasive replies to the members' questions, referred to the memorandum submitted to the subcommittee by the DHSS as a "pathetic document" revealing what he called an "active disinterest" in the matters under review.

Mr Leadbitter's wrath descended in particular on Dr T. J. B. Geffen, a senior principal medical officer at DHSS who represents the department on GMAG, but who told the committee that he has no particular experience or training in the techniques being discussed, and that his role was essentially that of providing a channel of communication between the department and GMAG.

Dr. Geffen, who was a hospital physician before joining the DHSS, told the MPs that he did not feel this role required any particular expertise, and that he felt there was no need for the DHSS to employ anyone with such experience since advice on technical matters relating to advances in DNA research could be obtained from consultants.

Given Dr Geffen's "relatively small" contribution to GMAG, the MPs therefore wanted to know why he had been chosen to represent the UK on an expert committee which had prepared draft directives on genetic manipulation for the EEC. They were not satisfied with the answer that the word "expert" in such a context meant someone with broad experience in the matter under discussion.

Mr. Arthur Palmer, chairman of the select committee, said that he felt the DHSS was taking a negative approach to the question of both the risks and the benefits of recombinant DNA research, and that the committee would try to put questions to Mr David Ennals, Secretary of State for Health, "to see if this policy of detachment is the best one".

David Dickson

Forest destruction must be halted, says report

THE Earth's forests are now decreasing in size annually by at least 11 million hectares—the area of Bulgaria—according to the latest Worldwatch report. It warns that man's destruction of tropical forests "is taking an enormous economic and environmental toll".

The study's author, Erik Eckholm, points out that the "fundamental importance of forests to human well-being" is generally ignored by those who analyse the basic needs of the world's poor to reduce the forest deprivation now suffered by many". (The Worldwatch Institute is doing its best to cure the blindness: the very first Worldwatch paper was Eckholm's 'The Other Energy Crisis: Firewood'.)

Information about the extent and condition of the world's forests is remarkably scanty, government statistics are frequently inaccurate and "sometimes doctored outright", the report says. But Eckholm estimates that approximately 20% of the Earth's land is now covered by dense forest—that is about half of the area that would be forested in the absence of man. Another 10% of land is "open woodland".

The forest area of North America and Europe is roughly stable. Almost all the loss is occurring in the humid tropical forests of Latin America, Asia and Africa, where Eckholm says the crude deforestation figures greatly underestimate the damage because "they reflect neither the massive degradation of timber and other biological resources occurring within many still-standing forests nor the severe depletion of open woodland and countryside vegetation that currently blights most third world countries".

The three principal causes of deforestation are, in order of importance, the unplanned spread of agriculture, firewood collection for cooking, and indiscriminate timber harvesting. Tree planting makes up only a small fraction of the loss.

"As a result the real prices of wood and wood products are likely to rise substantially over the coming decades . . .", Eckholm writes. "Meanwhile the continued loss of forests will accentuate the environmental costs of denudation already apparent in many countries—erosion, desertification, siltation, flooding and the extinction of species." And, he adds, deforestation may rival fossil-fuel burning as a source of atmospheric acrbon dioxide.

Although evidence for the economic consequences of deforestation is extremely scarce, Eckholm argues that it has been a major driving force behind the past decade's worldwide inflation. The price of wood has been rising in real terms by 4% a year during the 1970's, he estimates—and the increases have been most severe in the third world.

"A simple board costs twice as much in Pakistan as in the United States though the income of the average American is 46 times that of the average Pakistani", Eckholm reported. Families in some West African cities spend ¼ of their income on firewood.

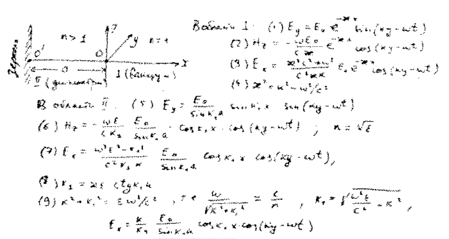
0028-0836/79/0277—0590$01.00

But the study concludes on an optimistic note. International aid agencies and politicians in developing countries are becoming more aware of the need to protect and manage forests. And the dismal record of tree planting in the third world—millions of young trees uprooted or nibbled to death by livestock—is showing signs of improvement in places where the "community forestry" approach is adopted. This means giving villagers the means to meet their own requirements and protect their own growing trees, Eckholm says, rather than imposing planting programmes in which they have no say—as has happened too often in the past.

The astonishing success of forestry in post-revolutionary China is the best known example of this philosophy. But Eckholm says the "success story of the 1970's" is South Korea. There a strong national commitment, combined with new village-level forestry associations, has covered one-third of the country with trees in the past decade and nearly solved an acute firewood crisis.

Worldwatch Paper 26, 'Planting for the Future: Forestry for Human Needs', is published by the Worldwatch Institute, Washington DC, at $2.

A day in the life of Yurii Orlov



A jailed dissident is keeping up his scientific work in a Soviet labour camp.

Vera Rich reports

Yurii Orlov, founder-member of the Moscow Helsinki monitoring group, was arrested two years ago this month. Unlike Academician Andrei Sakharov, who has virtually given up scientific work to devote himself to human rights, Dr Orlov, until the moment of his arrest, considered himself a scientist. Indeed, his letters from prison (which reached *Nature* recently) indicate that he is still attempting to pursue his research.

Until his trial last May, Orlov was held incommunicado. After his trial he was permitted to write the usual two letters per month, and immediately began to request writing materials and scientific texts. "I'd like to have Landau's quantum mechanics", he wrote to his wife in July, "it's lying on the shelf".

In the same letter he reports on his work in progress. "I'm constantly doing scientific calculations. . . . As you know, I've already completely finished one paper on logic, when I've copied it out, I shall send it officially to the Landau Institute of Theoretical Physics, to the Director."

However, two papers written during his pre-trial confinement had been confiscated. The next letter suggests, obliquely, that he was contemplating a hunger-strike if they were not returned.

Three weeks later, he was still anxious about the fate of these papers, and further perturbed that his paper on logic had not reached the director of the Landau Institute. But a long postscript to be passed on to his scientific friends outlined his latest train of thought. "While I was in quarantine, I did a small calculation for myself. I considered whether it was possible, by passing a beam of light along a wave-guide (i.e. with total internal reflection), to obtain beyond the limits of the wave-guide, in vacuo, an electromagnetic wave extended to a fairly great distance."

But the conditions for such quiet scientific reflection had already come to an end. In mid-August, Orlov had been transferred to a labour-camp where he found himself doing heavy physical work at an altitude of more than 1,000 m which left him completely incapable of any serious scientific activity.

By mid-October, when he had moved to another camp, No. 37, his letters once again show interest in scientific matters. One letter deals almost entirely with problems of cybernetics and his concept of "wave logic". There are interesting references to past discussions with Gol'fand, Rozenshtein—presumably within the framework of the refusniks' "Sunday seminars" of which Orlov was one of the few non-Jewish members.

But his conditions of work were still those of hard labour. "I'm working in the plant all week now. I had a choice: cutter or turner. The cutting shop makes a great deal of noise; in the turning shop you have to keep spinning around. I chose the turning shop. I'm still a learner: how it is possible to fulfil one's norm, I still can't imagine. . . ."

Yurii Orlov has seven years to serve in the labour camp, plus five years "internal exile". The avowed purpose of work in a labour camp is rehabilitation through service to the community. In almost every respect, conditions for political prisoners have improved considerably in the 25 years since Stalin's death. The one exception is that of scientists. As Orlov's friend, who forwarded the letters to *Nature* pointed out: "In Stalin's time, scientist-prisoners did research in special prison laboratories — Solzhenitsyn's *First Circle*. They didn't have to waste their talents in physical labour, as Orlov does". ☐

Soviets seek US collaboration over biosatellite

SOVIET space biologists have invited their US opposite numbers to take part in the experimental programme for the next Soviet bio-satellite scheduled for the end of 1979.

This proposed venture was announced by Dr Nikola Gurovskii, a leading member of the Soviet team shortly before a new agreement was signed extending cooperation between the Academies of the two countries. Much of the agreement dealt with details of exchange visits (up to 100 person-months per year) and research visits (16 from each side per year of from 3 to 12 person-month). However, there was also a general acceptance of the desirability of using the new agreement to place greater emphasis on cooperative activities, dealing with important scientific problems—a slot which would neatly take in the bio-satellite.

Dr Gurovskii said that this satellite would include 13 joint experiments. For the first time, the effect of weightlessness on mammals (rats) and birds (quails) would be investigated. There would be further investigations of the physiological effects of space-flight, and also tests on a new "anti-radiation" medicine, using dosimeters manufactured in the US.

These latter aspects are of particular interest to Soviet space medicine, according to a recent article in *Pravda* by Dr Avetik Burnazyan. He stated that the decisive factor limiting space-flights is no longer a technical one, but the ability of the organism to re-adapt to Earth conditions.

The proposed joint biosatellite programme will not be the first time there has been such cooperation; similar though less ambitious joint programmes were carried out on the Kosmos-782 and -936 satellites.

In Dr Gurovskii's opinion, however, the extension of such cooperation is of major importance It is becoming ever more difficult, he said, to develop science in a "narrow national framework". For "truly outstanding results", international cooperation is essential.

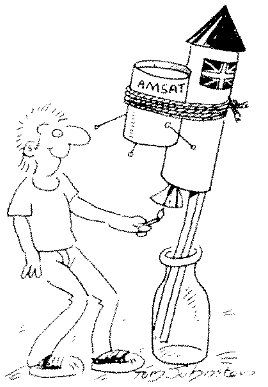
news in brief

Unions refuse to enter plutonium areas at Aldermaston: Management at the UK weapons research plant at Aldermaston has tried unsuccessfully to reopen work areas that have been closed since last August when 12 workers were found with excessive plutonium in their lungs. According to a spokesman from the Ministry of Defence the buildings are open in the active areas but restaffing of the buildings "has not been achieved". The MOD says that the issue under negotiation is danger pay but that it would be "inappropriate to disclose the details". According to the *Observer* (18 February) the unions are demanding £10 per day and management is offering 13p per hr. Bob King, shop steward of the Transport and General Workers Union at Aldermaston, the largest of the four unions involved, says the issue is not danger pay. "We've never said that. It's a term adopted by the newspapers." The TGWU is demanding that the area be made safe before they will allow their members to work in it. The unions will rely on health specialists in their national offices as well as local staff experience to insure that reasonable safety standards are met.

KGB clamps down on Sunday seminar: Reports from Moscow indicate new KGB pressure against the Sunday scientific seminar for refusniks. It is feared that the authorities may be trying to stamp out the seminar altogether—perhaps before the Einstein centenary next month focuses attention on the Jewish contribution to science.

A criminal file, No. 41035/38-75, has been opened on Viktor Brailovskii, the seminar leader, and a certain Avram Yoffe, from Leningrad. One of the people questioned in connection with this file was told by the interrogators that charges were being formulated and a trial could be expected "quite soon". One disturbing fact is that the investigations have been extended to the non-refusniks who have been attending the seminar.

Budget cuts threaten London medical schools: Lord Annan, Vice Chancellor of London University has set up a working party to investigate the financial viability of the University's 12 general medical schools, five dental schools and 13 postgraduate teaching and research institutes. Chaired by Sir Brian Flowers, Rector of Imperial College, the working party is to investigate the effects of further reductions in funds to the university and will prepare plans for the closing of specific schools if it finds this necessary. The action was taken after the Joint Medical Advisory Committee heard numerous complaints that budget cuts were impairing the quality of training. The university trains 30% of British doctors. In 1977/1978 8,250 medical and dental students were enrolled, of which 6,700 were undergraduates and 1,550 were postgraduates.



UK to build amateur spacecraft: Amateur radio enthusiasts at the University of Surrey are to build the UK's first amateur spacecraft—a satellite carrying a series of high frequency beacons which will be used by radio amateurs to study the effects of the ionosphere on radio-wave propagation. It is to be built in close collaboration with the international Amateur Satellite Corporation (AMSAT), the Amateur Satellite Organisation of the UK (AMSAT-UK) and the Radio Society of Great Britain. At an estimated cost of £150,000, the satellite should take two years to build. It is expected to be launched early in 1981 into a polar orbit at a height of 900 km. As all of AMSAT's previous eight amateur satellites have been launched by NASA, it is likely that NASA will be approached to launch this one too. The one exception, however, is the German-built AMSAT satellite which is due for launch by Ariane.

Swiss nuclear safety referendum result: Strict nuclear reactor controls (*Nature* 15 February, page 508) were rejected by the Swiss electorate on 18 February by a vote of 965,271 to 919,217. Nine cantons voted for the referendum and 13 against it. The 49% vote in favour is considered to be a surprisingly good result for the nuclear opposition since the nuclear industry spent 20 million francs on its campaign. So says André Froidevaux, of the National Co-ordinating Committee of Swiss Anti-Nuclear Organisations: "the nuclear lobby successfully exploited working class fears that jobs would be lost if the referendum passed".

An alternative law has been put through parliament. But the anti-nuclear movement has gathered 50,000 signatures to force another national vote on this law on 20 May. The new law gives parliament the right to veto new power stations and requires the need for a station to be documented. There is also a provision giving parliament the right to expropriate land for nuclear waste disposal. This law will be opposed by the National Coordinating Committee on the grounds that it offers virtually no effective controls to reactor development.

Cambridge designers plan low energy homes: A new design of terrace houses that will cut heating costs by 75% from £120/yr to £30/yr has been proposed by the Cambridge based firm, Ambient Energy Design. Their plan, which received first prize at the Energy Show now underway in Birmingham, makes use of better cavity insulation, double glazing units with infrared reflecting film between the panes, roll shades for night time insulation, and a conservatory which will trap solar heat. Gerald Foley of the International Institute for Environment and Development calls the savings "impressive". According to Foley, 30% of primary energy in the UK goes to housing of which two-thirds is for space heating. Thus a cut in heating requirements of 75% means a savings of 15% in the overall energy budget. Members of AED are convinced that low energy consumption represented by the above measures is "economic and realistic and will become commonplace."

Ambient Energy Design—House Heating for the 1980s. 6 Apthorpe Street, Cambridge CB1 5EY, £1.50.

Third World think tank proposed: S. S. Ramphal, Commonwealth Secretary-General has proposed to the South-North Symposium held in Tanzania last December that a Geneva-based research organisation be created to back up a Third World secretariat that can be competitive with existing organisational alliances of the developed world. In 1977 there were over 2,000 meeting days for UNCTAD alone and only 56 of 117 members of the Group of 77 developing countries had missions there. In comparison, organisations like OECD, EEC, and NATO exist to provide cohesion amongst the developed countries. Ramphal proposes that an OECDC, Organisation for Economic Cooperation among Developing Countries, be formed. The OECDC will "of necessity, be technocratic and multinational". Technological improvements in data storage, retrieval and information processing are necessary for the South to negotiate successfully with the North.

US report fails to bridge gap with Third World

The US delegation's paper for the UNCSTD conference in August is a disappointing document, writes **Ward Morehouse**

The long-awaited US National Paper for the UN Conference on Science and Technology for Development has made its appearance more than five months after the UN deadline for submission of national papers. It is strong on diagnosis, but woefully weak on remedies for the economic and social ills of developing countries which are identified in the paper; and unless the US is markedly more forthcoming at Vienna, this document will slip into the oblivion of history as yet another contribution toward the widening gap between profession and performance by industrialised countries toward the Third World.

Let us start with what is right in the report. There is recognition that the transfer of proprietary industrial technology has sometimes had a polarising impact on Third World economies; and that the deals struck by multinational corporations may not have always been fair to developing countries. Indeed the US paper urges that steps be taken to strengthen the negotiating skills of Third World countries on the grounds that more equitable bargains are likely to be more durable.

And the US report rightly recognises the failure of development strategies seeking solely to maximise growth. (Though its assertion that "the 'trickle down' strategy is now dead" taxes the indulgence of many observers.)

There is even recognition of the vital importance of building a strong science base in the Third World and an acknowledgement that most development assistance, focussed on short-term projects with immediate impact, "did not alter developing countries' continuing dependence on the initiatives of the scientific centres of the Northern Hemisphere". In a similar vein the report recognises "the need for developing countries to establish their own policy framework and to set their own priorities", although the report freely indulges in the imperialism of social priorities by repeatedly asserting the primacy in US development assistance of meeting basic human needs.

But the outstanding omission in the report is its failure to reflect the ambivalence of US policy toward the Third World.

In view of the lacklustre and self-serving character of most (but not all) of the other industrialised country national papers for UNCSTD, searching political self-analysis may be too much to expect. But the promising effort to analyse the economic and social shortcomings of US science and technology and other development policies stands in sharp contrast to the lack of political analysis.

While the US and other industrialised countries would no doubt like to see the worst forms of human poverty eradicated and a "self-generating" process of equitable economic growth accelerated in the Third World in the hope of reducing the possibility of overt and violent conflict between North and South, they are also interested in maintaining or extending political and economic dominance in the international system.

This dominance will give them an assurance of continued access to export markets and raw materials in developing countries, thereby helping to retain and enhance their relatively affluent living standards. And as other forms of economic and military power decline, technology is becoming an increasingly attractive and potent instrument for maintaining that dominance. President Carter's National Security Adviser, Zbigniew Brzezinski, has said that "the emergence of more advanced Third World countries like Brazil and Korea as new centres of rapid industrial growth means that the older industrial countries have to rely increasingly on technological innovation to maintain their place in the world."

Therefore it is hardly surprising that the US paper makes no direct reference to Third World efforts to change the rules of the game—for example, the proposed code of conduct on transfer of technology being negotiatied in UNCTAD or the forthcoming conference to consider revision in the Paris Convention on patents.

The report even asserts that "the US Government has been generally neutral toward commercial transactions of US private firms" ignoring the strong political support in international negotiations the government gives to positions which seek to maintain the *status quo* in international technology and investment flows and which serve well the interests of US multinationals Only the scantest reference is given to the powerful influence which US tax, investment, tariff and trade policies have on these flows.

Likewise the report gives little recognition to powerful domestic political and economic interests which shape US development and trade policy toward the Third World—as in the attempt by adversely affected US producers of vegetable oil and other products to prohibit use of US contributions to the World Bank and other multilateral financial institutions for projects designed to increase output of these products in developing countries.

The centrepiece of the US response to these problems is the proposed Foundation for International Technological Cooperation, although it is well known in Washington that the Foundation faces stiff opposition to its creation in Congress and even within the Executive Branch and may never come into being, let alone with the degree of autonomy and magnitude of resources to make a real difference in overcoming the failures of past policy and performance. All in all, it is pretty mild therapy for such a serious set of maladies as identified elsewhere in the US national paper.

The greatest defect of all in the US paper is a failure to recognise that the industrialised countries, and the science and technology on which those countries have a near monopoly, are as much a part of the problem as they are of the solution to the ills of the Third World. The insatiable demand for consumer goods by the rich minority of the world's population has generated technologies which are displacing millions of previously independent farmers and artisans in the Third World from their livelihood.

In the words of the Poona statement calling for open debate at UNCSTD on science, technology and the human condition in the modern world: "They would be players in the theatre of the absurd if they did not occupy positions of power and influence in the real world of today. Humanity must regain its sanity by reasserting the nature of scientific inquiry as the pursuit of truth, leading to technologies which liberate the many rather than facilitate control by the few." ☐

● Last week, President Carter announced the expected reorganisation of the US foreign aid programme. A new International Development Cooperation Administration (IDCA) will administer 2.7 billion dollars of non-military assistance programmes currently controlled by the Agency for International Development. IDCA will include the proposed Foundation for International Technological Cooperation (*Nature*, 25 January) but will be only semi-independent. The State Department and the Treasury will retain ultimate control of any major policy decisions. ☐

Ward Morehouse is president of the Council on International and Public Affairs, and teaches at Columbia University.

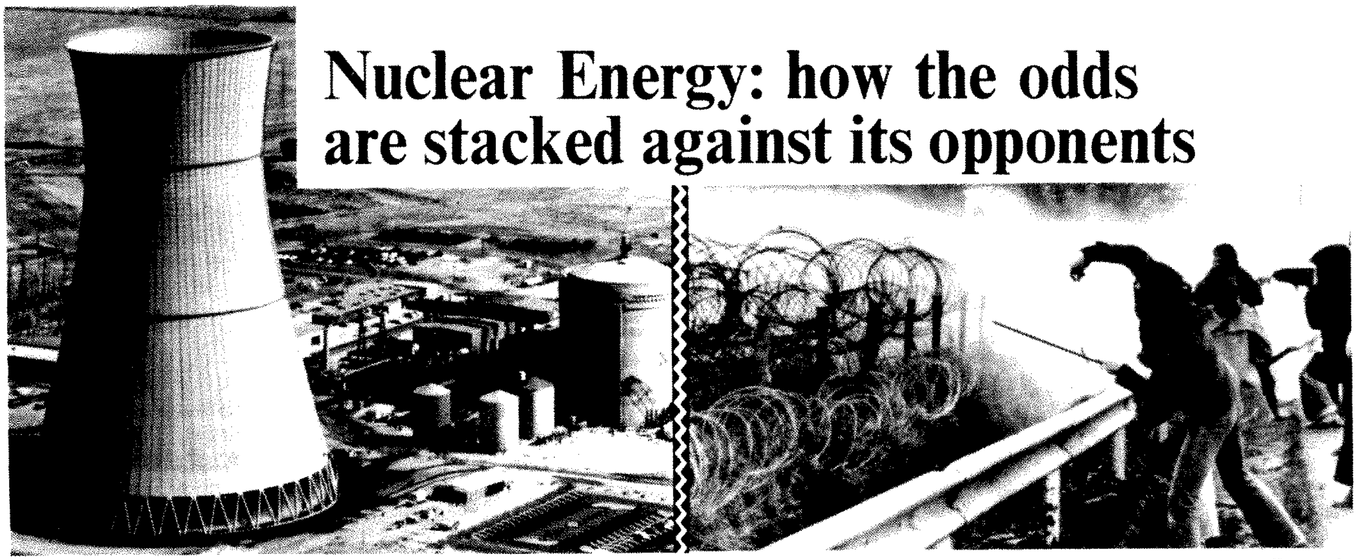
Nuclear Energy: how the odds are stacked against its opponents



● PETER TAYLOR explains why he feels that risk assessment is inadequately incorporated into democratic decision making in the UK.

THE debate over the safety of nuclear reactors illustrates a general problem of dealing with the impact of a technology, namely that the issues are assumed to be primarily 'scientific' and 'technical', and thus to be the exclusive field of 'experts'. Where procedures have been set up to make energy policy decisions or recommendations in the light of this controversy—as at the Windscale public inquiry—expert witnesses have held the arena and a judge appointed to sort out the "facts" and the "truth". At Windscale all witnesses were sworn to "tell the truth, the whole truth, and nothing but the truth". But, as Dr Brian Wynne, who gave evidence at the inquiry, said later: "You can expect a scientist to tell the truth, and nothing but the truth, but not the whole truth."

At the inquiry, Wynne had set out to show how the nuclear controversy differed from true scientific debate. The guarantor of truth in science, he argued, was pluralism in research, availability of information and open critical debate; but the nuclear debate was clouded with secrecy in crucial areas, and critics had totally inadequate resources to match proponents. In safety assessment, for example, there was only one body of facts according to one set of assumptions. Furthermore, scientists within the nuclear institutions, who might wish to dissent, were rigidly controlled by management and by the Official Secrets Act.

The possibility of a major escape of radioactive particles, however much it may now be dubbed incredible by the operators, has influenced siting policy. The early Magnox reactors were all built well away from conurbations. Then, in the late 1960s, pressure mounted to site new reactors near load centres and a review of siting policy took place. The Nuclear Safety Advisory Committee reported that "the major contribution to public safety lies in the standards achieved by design, construction, and operation of the plant". The Ministry of Power then reported to Parliament on 6 February, 1968, that the new advanced gas cooled reactor (AGR) could be operated "nearer to built up areas than we have so far permitted".

At the time of this policy change, the most publicised aspect was the inherently safer design of the AGR, using pre-stressed concrete for the pressure vessel and internal boilers. However, it was also realised that a large release would have a huge impact, however remote the siting. How far this affected siting policy is not clear.

This period of nuclear development was essentially uncontroversial. Assessments of risk were carried out within the nuclear establishment and accepted as adequate by politicians or closed working groups. It was during this period that risk assessment evolved the technique of "probabilistic analysis". Reg Farmer, at the United Kingdom Atomic Energy Authority, developed it as an aid to the designer in deciding what degrees of redundancy and containment might be reasonable to incorporate. He sought target probabilities of failure and the consequences and compared them with other industrial hazards.

The method has its limitations and, to his credit, Farmer has been quick to caution the nuclear industry for taking too much credit for a few hundred reactor-years of safety, and for "failing to see or adequately have regard to all those minor and sometimes major features of equipment or of organisation which might nearly have led to disaster".

Unfortunately this caution has not been repeated by some public advocates of nuclear expansion. The target probabilities of Farmer's curves of frequency against magnitude of effect (in deaths) have acquired a reality comparable with the facts of meteorite impact, and the frequency of dam failures, aircraft crash, and so on. For Sir John Hill, chairman of the UKAEA, such curves "show the probability of . . .", and for Sir St John Elstub (together with various presidents and vice-presidents of certain engineering and chemical institutes in a letter to *The Times*) the fact that Professor Rasmussen "has calculated" the chances of a severe accident for 100 power plants at one incident in 100,000 years is adequate assurance (a conclusion since repudiated by the US Nuclear Regulatory Commission).

The Flowers report served in some way to redress the balance and introduce critical comment into the public arena. The commission noted that in probability analysis and attendant fault-trees not all failures could be foreseen nor all components ascribed a frequency of failure. They concluded: "Whether the safety performance is achieved in practice will depend to some degree on factors assumed in the analysis, such as the quality of maintenance".

Despite this critical attitude to assessment, they were led to conclude that estimates of damage following an accident "must be presented in probabilistic terms". But, in our view, probabilistic presentation obfuscates rather than illustrates the potential effects. A range of incidents under specific conditions of wind and weather, including the worst of such conditions, should be presented. Probabilities are often meaningless: the most that can be said it that the worst case is less likely than the others.

The argument against worst case site-specific studies has always been that when disasters have occurred, the worst has not happened. After the Amoco Cadiz we can expect that this is not an argument that will be repeated for oil slicks. And yet, there is still a

0028-0836/79/0277—0594$01.00

reluctance to publicise the worst that can happen at Canvey Island or Hinckley Point. We suspect that Justice Parker's attitude prevails: in view of the (accepted) probabilities, such studies would "unnecessarily alarm the public".

That the public might be alarmed is evident when one considers that Flowers' example of a reactor (AGR) accident's consequences, and the NRPB/NII Breeder study, both admit that, under adverse weather conditions, casualties might be ten times worse: in the former case 100,000 casualties; in the latter 600,000.

There is a need for publicly available site-specific studies for AGRs and FBRs (fast breeder reactors) that explore the whole range of potential accidents and which do not slavishly accept the probability calculations of the nuclear establishment. In this, Britain lags far behind the United States and some European neighbours. In the US there have been open critical reviews of risk assessment, aided by the leaking of internal reports, the defection of industry-based scientists, the existence of the Union of Concerned Scientists and the operation of a Freedom of Information Bill. There has thus been an open reassessment of the work of closed expert groups. The most forthright report is that of the American Physical Society's study group on Light Water Reactor safety.

This pattern has been repeated in Sweden, Denmark and Holland, Austria and West Germany, often with the governments funding critical experts. In some cases, dissenting reports have been published by the government printer and incorporated into the procedures leading up to energy policy decisions. Most recently, in West Germany, a panel of 20 leading international, critical experts has been commissioned to review the proposal for reprocessing at Gorleben.

But in the UK, there has been no major reassessment of the work of closed expert groups. Critics are expected to fund their own safety analyses, without research facilities and without access to internal reports on which to base assessments.

Two examples from the work of our group may serve to illustrate the need for independent assessment.

- When the NRPB (National Radiological Protection Board) fast reactor study was published, press comment was largely restricted to assertions of probabilities such as 1 : 1m, and of the worst case being 60,000 casualties. Having been given access, at Justice Parker's instruction, to the UKAEA computer programme, we were able to run the NRPB calculations (which were for a notional site) for a specific locality (we chose Kalkar in West Germany). We discovered that the NRPB had chosen not to present their own worst calculations—the results of one weather category which led to 600,000 casualties. Our site-specific study, having altered only the population data on the programme, produced over 900,000 casualties.

- Hinckley Point has already suffered a potentially severe "loss of coolant" incident. A pipe-break and simultaneous valve failure led to the loss of both primary and secondary cooling. Dr Franklin of the Nuclear Power Company, when asked at Oxford recently about the ascribed probabilities of these events, said he thought cooling had been restored almost immediately through the use of fire-hose fittings. This statement did not accord with that of the Energy Minister in a written parliamentary answer, where we learn that cooling was lost for three hours and that fire-hose fittings were not present on that mark of AGR.

The scale of concern may be judged from the following extract from the proceedings of a Symposium in Vienna in 1967: "Cave and Holmes of the CEGB gave a probability of failure for primary and secondary cooling of 1 : 100,000 per reactor lifetime per independent system. Furthermore they praised the inherent safety of the AGR (over the LWR), in a loss of coolant situation, in that the heat capacity of the boilers, etc., was such that there was a period of three to four hours before the fuel cans would melt."

In the light of this time period, the Energy Minister's comment that there was no danger of a release during the period of loss of cooling takes on a new meaning.

Our concern at this uncritical acceptance of safety assessment has heightened recently with the public debate on the risks of different types of energy production. The Rasmussen-type probabilities have now been factored in to nuclear safety statistics. Thus one severe accident killing, say, 10,000 people in so-many-thousand years is incorporated into a global deaths-per-Gigawatt-year in the same manner as mining deaths are fed into the coal generating option. This initial work by H. Inhaber of the Atomic Energy Board of Canada finds that the nuclear option is safer than either coal, oil or solar. Lord Rothschild used this study in a televised broadcast on risks of energy production.

But Inhaber's work assumes reactor accident frequencies which may or may not be borne out in practice. This has, unfortunately not inhibited its use in the industry's public relations The situation is more disquieting considering that the nuclear establishments have available to them the fruits of an IAEA sponsored research programme on the comparability of risks which clearly highlights the limitations of Inhaber's approach.

The selective use of the results of scientific research, often in an unrefereed form, raises important questions for the future structure of public debate. The problem will arise when considering the forthcoming FBR inquiry. It is our view that AGR and FBR fault analyses will have to be publicly presented and discussed before comparison of energy option risks can be meaningful. If critical experts are to be expected to produce safety analyses, then they will have to have access to official information, if not government support, for their research.

Finally, there is an area of research relevant to safety assessment that is continually neglected, namely the "social facts" relating to the nature of the dispute itself, the role of science, and of controversy. What groups are involved in the debate and what benefits or risks accrue to each (in the nature of contracts, jobs, risk of accident or pollution)? How is risk perceived and evaluated within these groups and what are the components of attitudes? What correlations are there to levels of knowledge of the technology? What procedures exist for debate, participation and information-exchange and how effective have these procedures been in the past?

The controversy itself may bring forth bitter and unresolvable conflict. Once more we find it disquieting that the UKAEA does not choose to publicise the results of further IAEA work in this field. The work of Pahner, Novotny, Stallen and Meertens points clearly to a realisation that the controversy has no resolution that people are divided by a basic evaluatory perception of technology and progress.

We believe that herein lies a fundamental question. The nuclear issue is important as a first testing ground for democratic flexibility. The institutions of industrial growth and technological progress realise that the call by the "alternative" camp for openness, reassessment and participation, however sincere in itself, exposes aspects of their technology which it feels a lay and mistrusting public may not accept. Thus there is a retreat into secrecy and, paradoxically, a massive public information programme. This in itself generates further opposition. We are not convinced that the UK government realises the full impact of this conflict.

Peter Taylor is co-director of the Political Ecology Research Group. This article is based on a talk he gave at a conference on the politics of fast breeders in London at the end of last year The conference proceedings are to be published by Macmillan.

The Piltdown hoax: *cui bono?*

SIR,—By far the most sensational feature of the Piltdown hoax, that has remained hidden from the public gaze for so long, is that it was planned and executed by eminent scientists against one of their own number.

Until recently there have been two main hypotheses regarding the identity of the perpetrator of the Piltdown hoax. That espoused by Weiner (*The Piltdown Hoax*, Oxford University Press, 1955), inferring the guilt of the amateur Dawson, is far the more acceptable as it absolves the academic world from any involvement. The other view is that Dawson was the scapegoat, and the hoax was part of a conspiracy on the part of scientists to delude the public into accepting the anti-religious idea of human evolution (M. Bowden, *Ape-men fact or fallacy?* Sovereign Publications, 1977). This thesis, of which there are hints in Langham's letter (18 January, page 170), even suggests that Smith Woodward "may have been a willing accomplice". Hence, Elliott Smith, who nailed his banner firmly to the Piltdown mast, could be imagined to have been the instigator.

Douglas (2 November, page 11) has provided a signal service by making us look afresh at the evidence and consider a "grudge against one of the principals" as a fruitful line of enquiry. The incident of the Sherborne horse's head, if nothing else, was a successful and deliberate demonstration by Sollas of Woodward's incompetence. In this context, it is indeed difficult to imagine Dawson being party to any conspiracy aimed at belittling his close friend of many years standing (from 1884 until his death in 1916). He may possibly have been persuaded to help "encourage the evidence", and it is difficult to avoid postulating some kind of direct involvement. The way in which the desperately wished for lower jaw was flicked up by Dawson's pick, so that it landed literally at Smith Woodward's feet, has such an air of theatre about it that one is bound to be suspicious of such a startling coincidence. When the search was on for the missing canine, Teilhard de Chardin sat down to rest on a heap of gravel that Dawson and Woodward had already sifted. They actually told him that there was no point in searching there, but within a few minutes of casual probing with his fingers the canine appeared, yet another startling coincidence. (This event might well place Teilhard de Chardin among the suspects). The subsequent sudden appearance of the "cricket bat", from the soil under the hedge where they usually lunched, was surely stretching credulity to breaking point. Everything that Smith Woodward wanted, turned up and, moreover, in the order in which he wanted it.

Every good hoax, to be effective, needs to carry certain hallmarks that allow it to be recognised as such by all and sundry, with the main exception of the victim for whom it was designed. Let us now look, not at Woodward's friends, but at his enemies. Douglas has already drawn our attention to the strong possibility of Sollas being involved. Sollas was Britain's leading expert on fossil man, who had just given his Presidential Address to the Geological Society on fossil man and had recently published *Ancient Hunters* (1911). Here was a man who had pioneered over many years the technique of serial sectioning, which enabled palaeontologists to examine the internal structures of fossils that otherwise would never have been accessible for study, a technique which Smith Woodward contemptuously dismissed as a "mere toy". And here was Smith Woodward with pretensions, but no expertise, announcing his ambition to discover the earliest man, and moreover, in Britain. Was this not as close to an invitation as one could imagine?

Weiner (4 January, page 10) draws attention to Oakley's letter to *The Times* (7 November 1978) regarding Sollas's possible use of potassium bichromate, but he seems to have missed my reply (*The Times*, 25 November) refuting Oakley. My letter also mentioned that Dr M A. C. Hinton was the likely source of the medieval orang utan lower jaw and that Hinton had stated that the hoax was initially planned and executed within the Natural History Museum. Unfortunately the short paragraph referring to Hinton's possible involvement was edited out of my original article in *Nature* (2 November, pages 11-13).

In the spring of 1912 Dawson brought the five Piltdown skull fragments to Smith Woodward, but to be certain of its import, it was vital to find the lower jaw. In 1910 Hinton was given the status of a Voluntary Worker in Smith Woodward's Department of Geology to work on fossil rodents. He managed somehow to offend Smith Woodward to such an extent that in 1912 he transferred to the Department of Zoology to continue his work there (eventually in 1936 becoming Keeper of Zoology and retiring in 1945). The available evidence suggests that the medieval orang utan lower jaw came from a box of unregistered material from the Everett Collection to which Hinton then had access. Hinton (*The Times*, 4 December 1953) stressed that the zoologists in the museum would have unhesitatingly referred the lower jaw and canine to a chimpanzee had the material come within the orbit of the Zoology Department! He claimed that in their eyes G. S. Miller's analysis settled the matter and relieved them of the necessity of expressing any opinion and thus arousing hostility within the museum. In retrospect, this epistle from Hinton takes on a new significance.

From the people that knew Hinton well, it is accepted that he must have been involved in the promulgation of the hoax and it is even claimed that he "virtually confessed" to this, prior to his death. Nevertheless, there was always the nagging suspicion that there was a more knowledgeable figure in the background; Douglas's suggestion at last provides the clue to his identity. Douglas asks "Did they [the people who exposed the fraud] ever try to find out if Smith Woodward had any particular enemies who might do such a thing? No. They did not" If a crime is committed against an individual, the first task, having ascertained that the deed has in fact been committed, is to determine if anyone had a strong motive. Such an approach would have pointed in the direction of the Natural History Museum and Oxford. Without wishing to be uncharitable, perhaps this is the reason the grudge theory was never followed up. This would explain the cameo of Sir Gavin de Beer "rolling on his settee, wringing his hands and crying 'What can I do? What can I do?'" as the evidence on Piltdown unfolded. It is not a scandal for an institution to have been duped by a hoax, but if it transpires that it has been initiated in the same institution, it certainly is.

Finally Weiner's accusation of Douglas besmirching Sollas's reputation cannot be left unanswered. Given the circumstances in the 1910-1912 period, given the personality of Smith Woodward, I wonder how many people would have resisted the temptation "to present somebody, who is claiming to be an expert in a field, with something everybody would know is so ludicrous that he would make an utter fool of himself and be shot down in flames". The conspirators misjudged the perspicacity of their colleagues, although Waterston, Lankester, Boule, Miller and Weidenreich doubted the association of ape jaw and human skull from the very beginning. Above all, however, Piltdown engendered such an enthusiastic nationalistic fervour, that the critical faculties of the scientific community seem to have been overwhelmed, and *this* surely was the tragedy of Piltdown.

Pion interferometry of nuclear collisions

from Miklos Gyulassy

THE measurement of the space-time dimensions of nuclear interaction regions formed during high energy (~1 GeV per nucleon) nuclear collisions obviously calls for rather novel techniques. That interaction region (which we call the nuclear fireball) may be roughly cigar-shaped with longitudinal and transverse dimensions ranging between 10^{-12} and 10^{-13} cm and expanding with relativistic speeds on a time scale of 10^{-23} to 10^{-22} s. In that tiny, short-lived fireball, nuclear matter may be compressed to very high densities (~10^{15} gm cm^{-3}) and heated to enormous temperatures (~10^{12} K).

The physics of nuclear systems under such extreme conditions is now the subject of a new branch of nuclear science known as relativistic nuclear collisions. Recent developments in this area have been reviewed by Goldhaber and Heckman (*A. Rev. Nucl. Part. Sci.* **28**, 161; 1978). One of the most exciting new developments has been the application of pion interferometry to deduce the space-time geometry of that nuclear fireball. The principles behind pion interferometry and the first experimental results are discussed below.

The basic idea goes back to Hanbury-Brown and Twiss (*Nature* **178**, 1046; 1956), who first used the technique of second order intensity interferometry to deduce stellar radii. They made a remarkable observation for the chaotic, incoherent light emitted by stars. While the average intensity (photon count) measured by two detectors A and B was the same, $\langle I_A \rangle = \langle I_B \rangle$, and independent of the separation R_{AB} between the detectors, the average coincidence rate, $\langle I_A I_B \rangle$, did depend on R_{AB}. For large separations $\langle I_A I_B \rangle \approx \langle I_A \rangle \quad \langle I_B \rangle = \langle I_A \rangle^2$, but for small separations, $\langle I_A I_B \rangle \gtrsim \langle I_A \rangle^2$. From the dependence of $\langle I_A I_B \rangle$ on R_{AB}, Hanbury-Brown and Twiss were able to measure stellar radii.

The reason for this variation of the coincidence rate as a function of R_{AB} is now well known and found in any modern quantum optics textbook. It originates from Bose-Einstein statistics required for integral spin particles such as photons. It is the interference between the two parts of the symmetrised wavefunctions, $1/\sqrt{2}\{\psi_1(x)\psi_2(y)+\psi_1(y)\psi_2(x)\}$ describing two identical bosons that leads to the intensity interference, Physically, the enhanced correlation at small R_{AB} follows from the tendency of bosons to congregate in the same state.

Not long after the discovery of the HBT effect in astrophysics, it was rediscovered in high-energy physics in measuring correlations between identical pions. In high-energy physics it is called the GGLP effect (*Phys. Rev.* **120**, 300; 1960). Pions ($\pi^-\pi^-$) are also bosons and are thus subject to the same symmetrisation requirement as are photons. Consequently, intensity interference must also occur for chaotic pion fields. For pions, intensity interferometry involves the comparison of the coincidence rate of identical pions with momenta $\mathbf{k}_1$ and $\mathbf{k}_2$ to the random rate of observing pions with $\mathbf{k}_1$ and $\mathbf{k}_2$. Bose-Einstein statistics lead to an enhancement of the coincidence rate over the random rate for small momentum differences. The correlation function, defined as the ratio of the coincidence to random rate, is thus larger than unity for small $|\mathbf{k}_1-\mathbf{k}_2|$. According to a theoretical analysis by Kopylov and Podgoretski (*Sov. J. Nucl. Phys.* **18**, 336; 1974), the dependence of the correlation function on $\mathbf{k}_1-\mathbf{k}_2$ in fact measures the space-time Fourier transform of the pion source density. The relation between the measured pion correlation function and the source density obtained by Kopylov has been the basis of a great many studies of the space-time dimensions of hadronic interaction regions (see for example Enzell *et al. Phys. Rev. Lett.* **38**, 873; 1977).

Most recently the pion correlation data from high-energy nuclear collisions were analysed by a University of California, Riverside group headed by R. T. Poe. The reaction studied was $Ar + Pb_3O_4 \rightarrow \pi^-\pi^- + X$ using an Ar beam with 1.8 GeV per nucleon kinetic energy (Fung *et al. Phys. Rev. Lett.* **41**, 1592; 1978). In such reactions often more than 100 charged particles (p, π^+, π^-) are observed with negative pion multiplicities up to 15. These are the remnants of the violent explosion of the nuclear fireball. Pion interferometry has given us the first glimpse of the dimension and lifetime of that fireball before its explosion. The group reported that the average radius, R_0, and the lifetime, τ_0, of the fireball were $R_0 = 3.3 \pm 0.9 \times 10^{-13}$ cm and $\tau_0 = 5 \pm (?) \times 10^{-24}$ s.

Although the statistics are as yet too few to determine the longitudinal and transverse dimensions of the fireball separately, the measured R_0 agrees well with our expectations. However, most important, this experiment demonstrated the feasibility of pion interferometry in nuclear collisions. The next generation of experiments with the Bevalac at the Lawrence Berkeley Laboratory are expected to increase the statistics greatly. We will then be able to resolve much more clearly the geometry of these fireballs.

The discussion up to now has been concerned with intensity interferometry when applied to chaotic boson fields. As recently emphasised by Fowler and Weiner (*Phys. Lett.* **70B**, 201; 1977) the intensity interference pattern also depends on the degree of coherence of that boson field. Laser fields, for example, exhibit no intensity interference. The effect of possible coherence on pion interferometry is a topic of current theoretical investigation.

A final comment that must be made is that final state interactions must also be considered in connection with future work on pion interferometry. Unlike photons, pions can interact with each other and the remnants of the exploding fireball. The effects of final state interactions (especially the long-range Coulomb forces) must be unfolded from the measured correlation data before accurate geometrical and dynamical information can be deduced from those correlations. Such studies are also now underway. □

Exons encode protein functional units

from C. C. F. Blake

An important contribution to relationship between protein structure and the newly discovered mosaic structure of eukaryotic genes, in which coding segments of DNA (exons) alternate with non-coding segments (intervening sequences or introns), is reported by Tonegawa and his colleagues in this week's *Nature* (Sakano *et al.* page 627). The protein chosen was the constant region of the immunoglobulin γ heavy chain. Sequence studies and crystallography have already shown that the constant region is composed of three homologous structural domains: the C_{H1}, C_{H2} and C_{H3} domains. Each domain is composed of about 110 amino acids, folded into almost identical tertiary structures made up from seven β-strands. The C_{H1} domain pairs with the C_L domain of light chains to form, together with paired V_H and V_L domains, the Fab parts of the γ-globulin molecule. The C_{H2} and C_{H3} domains pair with equivalent domains of a second heavy chain to form the F_c fragment, which is separated from the Fab fragment by a hinge region. Each of these structures has a well defined function: the paired C_{H3} domains act in cell surface interactions, the paired C_{H2} domains in complement fixation; the hinge probably transfers information from the Fab to the F_c fragment; the C_{H1} pair is the attachment point for the light chain; the V_H V_L pair forms the antigen binding site; and there is also an N-terminal signal peptide. Thus the immunoglobulin molecule is composed of six discrete structural/functional units whose relationship to the exon/intron mosaic in the coding region could be most illuminating.

The DNA was obtained from mouse MOPC 21 myeloma by complete digestion with *Eco*RI nuclease and the identification of a 6.8 kilobase segment that contained the required sequence by hybridisation with cDNA prepared from MOPC $21_{\gamma 1}$ mRNA. The segment was recombined with the EK2 vector, phage λgt WES, and cloned. After digestion of the clone the position of the γ_1 coding region in the 6.8 kb fragment was determined by electron microscopy of the R-loops formed between it and the γ_1-chain mRNA. This revealed three small R-loops separated by two intervening double-stranded DNA segments, suggesting the presence of three exons interrupted by two introns. A restriction enzyme cleavage map showed that this interpretation was correct, but that there was an additional very short exon located between exons 1 and 2, giving a final pattern of 4 exons separated by 3 introns. Sequence analysis of the intron–exon boundaries and comparison with the known amino acid sequence of the MOPC $21_{\gamma 1}$ chain, revealed that the exons represent, in sequence, the C_{H1} domain, the 14-residue hinge region, the C_{H2} domain, and the C_{H3} domain. There seem to be no introns within the individual sequences coding for these units.

The conclusion from this study, that each of the six known functional units in the γ-globulin heavy chain is coded by a separate exon is most exciting. So clear cut is the correspondence that one is tempted to conclude that the problem of exons has been solved along the lines proposed by Gilbert (*News and Views* **271**, 501; 1978) in which the presence of exons was seen as allowing new proteins to be constructed from parts of old ones. The results reported by Tonegawa are exactly in line with this hypothesis, and show that individual exons can define even very small functional units, like the 14-residue hinge region, and not just domains or folding units as I previously suggested (*News and Views* **273**, 267; 1978). In view of the precise correlation between exons and the functional units in the immunoglobulins, the presence of three exons in the β-globin gene, when the protein cannot readily be divided into individual units of either structural or functional significance seems at first very puzzling. However, closer examination shows that the central exon corresponds very closely to the protein fragment that defines the haem crevice, and contains nearly all the amino acid residues that interact with the haem. Tonegawa's work implies that exons may reveal unsuspected functional protein units—perhaps like the 'minimal globin' outlined above—even when the joins are not visible in the protein structure. The thought that the exon/intron mosaic may carry the frozen evolutionary history of proteins makes one look forward to see whether further determinations of exon–intron patterns of other proteins of known structure support this view, or point in a different direction.

RNA splicing and polynucleotide evolution

from D. Reanney

Information flow in cells, is defined by the 'central dogma' as

DNA→RNA→Protein

But although the central dogma accurately describes the flow of information in modern cells, it probably fails to reflect evolutionary perspective. Considered from the chronological viewpoint a more accurate representation of the central dogma might be

$$\begin{tikzcd} & \text{DNA} \\ \text{RNA} \arrow[ur] \arrow[dr] & \\ & \text{Protein} \end{tikzcd}$$

This rewriting of a basic tenet of biology has come from several lines of evidence which strongly reinforce the view of Crick (*J. molec. Biol.* **38**, 367; 1968) and others that RNA is the primary genetic material. It is worth re-emphasising that most key features of the translation of genetic information depend on Watson–Crick pairing between (partly) complementary RNAs. Translation is mediated by interactions between different RNAs—mRNA:tRNA; mRNA:rRNA; rRNA:tRNA and rRNA:rRNA. The same was probably true of primitive 'metabolism'. With respect to a metabolic fossil such as the ribodinucleotide NAD, for example, one may ask why is a nucleotide 'handle' a necessary part of a molecule whose active group is nicotinamide. I suggest that the first steps on the road to precellular metabolism were taken when electron-donating and electron-accepting reactions were coupled by means of molecules whose 'handles' were complementary in the Watson–Crick sense. For example

*U*DP-X (red)→UDP-X (ox)
where *U* is paired with *A*
N*A*D (ox)→NADH+H (red)

Here the 'genetic' monomers A and U are used to bring the two elements of the redox reaction into appropriate juxtaposition; this is effectively what an enzyme does. The addition of

---

D. Reanney is Senior Lecturer in the Department of Microbiology, La Trobe University, Australia.

further nucleoide 'handles' would enhance not only the efficiency of the mechanism but also increase its specificity. Reaction specificity is another enzymatic attribute; in terms of this thesis, aminoacyl-tRNAs are but one surviving set of examples of a family of oligonucleotides equipped with non-nucleotide active groups.

Perhaps the most compelling argument for a primary role for RNA in early evolution has come from the discovery of RNA processing. At first sight RNA:RNA splicing seems to remove RNA from early genetic events rather than bring it closer to them. This is because splicing has to date only been demonstrated in eukaryotes. However, the assumption that eukaryotic DNA represents a more advanced type of genetic organisation than bacterial has been suspect for some time (Reanney, *J. theor. Biol.* **48,** 243; 1974). The discovery of split genes has added a powerful buttress to the argument (for a recent, detailed discussion see Darnell *Science* **202,** 1257; 1978).

It is clear that Darnell sees DNA as retaining the genetic function in these early splicing systems. However, the points made by Darnell are consistent with a primary role for RNA both in information storage and information processing. Thus 'mosaic' RNAs produced by splicing are *strictu sensu* recombinant molecules in that they contain data drawn from different parts of the genome. But whereas classical DNA recombination requires the concerted action of a plethora of different proteins (DNA ligases, repair enzymes, denaturation proteins, exonucleases, and so on, splicing requires only two (known) functions—a cleaving and a ligating capacity. Also 'consensus' sequence targets for RNA processing enzymes are short (about six nucleotides (Catterall *et al. Nature* **275,** 510; 1978)) regions on single RNA strands whereas DNA recombination only occurs if two duplex DNAs of strongly matching nucleotide sequence are brought into register. Splicing thus has the virtue of economy which can in this context perhaps be equated with 'simplicity'. It seems logical therefore to suggest that RNA:RNA splicing is the primitive mode of genetic recombination.

One of the better characterised processing enzymes is RNase P. This molecule is a ribonucleoprotein containing about 80% RNA; as such it resembles an undoubtedly primitive structure—the ribosome. Stark *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75,** 3717; 1978) have raised the possibility that RNase P recognises target sequences by RNA: RNA pairing. Since known nucleotide-recognising proteins (such as the *lac* repressor) select their substrates by exploiting the stereospecificity of proteins, the presence of about 350 ribonucleotides in an RNA-cleaving enzyme suggests that the processing of RNA molecules had been fixed into cell chemistry before the takeover of catalytic functions by proteins had been completed. The fact that RNase P processes the products of one of the most ancient surviving genes—that for tRNA—is consistent with this view.

The example of RNase P holds out some tantalising clues as to the origin(s) of the splicing process, conceivably at a time when effectively coded proteins had still to develop. X-ray crystallography has confirmed that the skeletons of 'working' RNAs trace out complex paths through three-dimensional space. Let us assume that RNA: RNA splicing was (and is?) mediated by RNA units which potentiate the cleavage of longer molecules at splice points ('cutter' RNA) and join shorter RNAs ('linker' RNA). (Conceivably both activities could reside in one molecule). A cutter can recognise specific bases in substrate RNA only if these are unpaired; similarly a linker can only act as a ligating agent if bases in the two separate RNAs are unpaired at or near the point(s) where the molecules are to be joined. Since the number and position of appropriately oriented, unpaired nucleotides is determined by the three-dimensional architecture of the RNA it follows that topology must have had a key role in the selection of the splice site—something which seems to survive into the present day since all (known) sequences flanking splice sites are too short *per se* to provide the needed specificity. The (at first sight) puzzling absence of strong internal Watson–Crick pairing at most known splice sites (Catterall *et. al. op. cit.*) is explicable if nucleotides near the site are required to be unpaired in order to provide a recognition mechanism through base-pairing with an independent RNA.

The importance of topology can be illustrated by reference to a specific example of enzymatic interaction with an RNA of known, complex morphology—tRNA. One of the most common modifications to tRNA is methylation, carried out enzymatically using S-adenosyl methionine (SAM) as methyl donor. The function of the various methylase enzymes is to ensure that methyl groups are added at the correct site on the correct base. What is often overlooked is that it is the previous folding of the polynucleotide that determines to a large degree the availability of the bases. So by selectively shuffling base sequences so that sites to be methylated occur in loops it is possible for a low molecular weight agent such as SAM acting at random to achieve relatively specific results. If a useful 'enzymatic' RNA sequence is found among a pool of variants this can be selectively amplified by the autocatalytic ability of duplex RNA; the reproducibility of the modifications (on which such useful enzymatic ability might depend) being ensured by the particular folding mode of transcript RNA.

What are the advantages of RNA: RNA splicing to a very early genetic system? Perhaps the most important is that the 'complexity' of polynucleotides can be increased in a modular fashion as a result of ligation between independently formed oligomers. Further, at a time when the number of effectively self-replicating RNAs was a rate-limiting factor in evolution, processing has the enormous advantage that multiple mosaics can be run off from essentially the same template; new sequences also result from the successive processings of one transcript (the production of multiple mosaics from one RNA was probably inevitable at the time when splicing enzymes had not evolved the precision needed to avoid reading-frame shifts in protein synthesis). Thus processing can maximise the number of sequences exposed to the test of selection in a way and at a rate unachievable through the slow rewriting of existing sequences by genetic noise. The adaptive advantages claimed for splicing (see Gilbert *News and Views* **271,** 501; 1978; Reanney *ICN-UCLA Symp. Persistent Viruses,* 1978) seem to apply with greater force at earlier than at later stages of evolution.

The emphasis placed on 'enzymatic' aspects of RNA implies that, in the absence of sophisticated proteins, the production of mosaics through processing may well have been easier to negotiate than the production of unit mRNAs through punctuation. Excised intronic sequences could readily be used as primers to maintain the continuing replication and transcription of template polynucleotide, thus relegating to RNA yet another role now carried out or aided by proteins.

With the takeover of genetic function by DNA, 'illegitimate' recombination may have complemented the processing mechanism. It is noteworthy that IS*1* and elements of the *att* site of λ contain promotor-like sequences (Landy & Ross *Science* **197,** 1147; 1977). RNA polymerase seems to be directly involved in a *recA*-independent recombination pathway of ρ DNA (Ikeda & Kobayashi *Proc. natn. Acad. Sci. U.S.A.* **74,** 3932; 1977). Illegitimate DNA recombination may thus preserve a memory of the primary role of RNA in early genetic processes.

Since splicing and illegitimate recombination between them provide an enormous pool of 'experimental' polynucleotides one may ask why generalised recombination occurs across the biological spectrum I suggest that this type of recombination developed from the proofreading function which seems to be a universal correlate of DNA synthesis. The proteins needed for generalised recombination could easily have been recruited from the molecules used in the cut and patch mechanism(s) on which proofreading depends One of the most striking things about generalised recombination is its conservative character. No information is gained or lost and gene order is not disturbed Significantly, branch migration and strand isomerisation show up base mismatches as transient heteroduplex lesions. Since these lesions can be recognised and repaired, generalised recombination could be regarded as an extension of the proofreading function from which it evolved. Preferential correction to wild-type rather than mutant genotype can be achieved, at least in phage λ, by enzymatic recognition of base mismatches in non-methylated (that is, newly made) strands (Meselson & Radman cited in *Nature*, **268**, 490; 1977). Thus reciprocal recombination between equal-length DNAs may, in part, be a mechanism for minimising variation, not promoting it.

According to this view the sequence of events in the evolution of genetic recombination was first, RNA:RNA splicing; second, illegitimate recombination and third generalised recombination. Legitimate recombination now acts as a brake on change, continuing evolution being nourished by the earlier mechanisms. □

Short period fluctuations in the Earth's magnetic field

from Ken Games

Up to about 10 years ago, it was generally believed that the magnitude of the Earth's magnetic field varied with periods of approximately 8,000 years on a world wide scale Thus in 1968 Cox (*Science* **163**, 237; 1968) produced a graph of variation in the geomagnetic dipole moment which was obtained by averaging data over 500 year intervals (Fig. 1) In recent years, however, researchers are finding local changes in the magnitude of the magnetic field which have periods of as little as 200 years and which show a change in the total field strength of up to 100%. The questions which now have to be answered are: how confident are we in the magnetic measurements used to determine these changes, and, if these changes are real, what is causing them?

The commonest material used in field magnitude determination is pottery. The main technique used to 'unlock' the magnetic record held in the pottery is that developed by Thellier and Thellier (*Ann. Geophys* **15**, 285, 1959), although many modifications to this technique have since been made. The basic Thellier and Thellier method involves heating a sample to, say, 100 °C in zero magnetic field and allowing it to cool to room temperature The sample is then reheated to 100 °C in a known laboratory field B_{lab} and again cooled. The decrease in magnetic moment m_1 after the first heating represents the magnetisation acquired by the sample in the temperature interval R.T. – 100 °C when the sample was first fired in the ancient magnetic field B_{anc}, and the increase in magnetic moment m_2 after the second heating represents the magnetisation acquired in the laboratory field. Thus the simple equation

$$\frac{m_1}{m_2} = \frac{B_{anc}}{B_{lab}}$$

enables us to determine B_{anc}. This process is then repeated at steps of increasing temperatures such as 200, 300, 400 and 500 °C. If the value of B_{anc} obtained from each step is the same then the result is assumed to be a reliable one. Several possible sources of error in this method have been known and taken into account for a long time. For example, the laboratory heating can cause changes in the magnetic minerals of the sample. This tends to happen at high temperatures, and many of the modifications of the method have attempted to monitor such changes.

Recently, however, two serious possible sources of error have been discovered The first source was reported by Fox, Aitken and Gunn (*Geophys. J. Roy Astron Soc* **53**, 153; 1978) when they discovered a shape anisotropy effect. Thus it was found that the thermoremanent magnetisation (TRM) acquired by a disk-shaped sample (25 mm in diameter and 6 mm thick) along the plane of the disk was about 20% greater than that acquired perpendicular to the plane. This effect seems to be similar to the self-demagnetising effect exhibited by kilns as shown by Aitken and Hawley (*Archaeometry* **13**, 83; 1971)

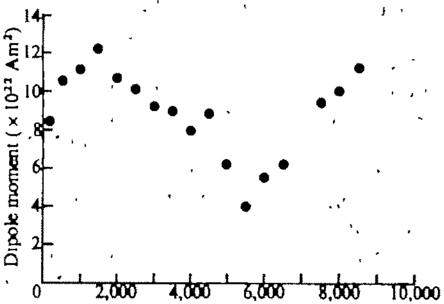

Fig. 1 Variations in geomagnetic dipole moment. Changes during the past 130 yr, as determined from observatory measurements, are shown by the slanting bar at the left. Other values were determined palaeomagnetically (Cox *op. cit.*)

The second source, reported by Rogers, Fox and Aitken (on page 644 of this issue of *Nature*) is another anisotropic problem, this time shown to exist on cylindrical samples 3 mm × 3 mm, which should therefore have no anisotropy due to shape. However, it was found that for samples whose cylindrical axis was perpendicular to the plane of the pottery, the TRM along the axis was up to 40% less than the TRM perpendicular to the axis. This is thought to be due to a preferential alignment of magnetic grains within the fabric of the pottery One would intuitively expect that this effect would be greater for wheel-made pottery than for hand-moulded pottery, but whether this is so or not, it obviously presents a problem in interpreting archaeomagnitudes which have been reported before this discovery. What is certain is that in future care should be taken to give the TRM in the same direction as the normal remanent magnetisation (NRM) was originally acquired, or at least to correct for the anisotropy effect. Even so, there is a further problem yet to be investigated This is the fact that when a sample first acquired its NRM it was part of a larger mass of ceramic, and no one really knows just what difference this makes compared with the acquisition of the TRM after it has been broken away from the larger mass.

One author who has made a correction for the fabric anisotropy is Walton (on page 643 of this issue). His results show a rapid rate of change in the magnitude of the magnetic field in Greece between 2000 BC and AD 400. As stated earlier, these are the sort of results now being found by several workers, and it becomes apparent if the diagram in Fig. 1 is compared with that of Walton, that by averaging over 500-yr intervals Cox has automatically lost the resolution which, given adequate precision of dating, could show the rapid short-period fluctuations now

---

K. P. Games is at the Oliver Lodge Laboratory, Liverpool University.

0028-0836/79/0273-0600$01.00

being seen. It is also clear that it becomes of vital importance to use material which is very accurately and reliably dated—preferably to within ±30 yr.. Where such dating controls exist, the magnetic results usually show the rapid short period fluctuations.

The major problem still to be answered, however, is what is causing these fluctuations, which can result in a change in magnitude of the magnetic field of up to a factor of 2 in a couple of hundred years. It is difficult to see how the main dipole field can change at such a rate, but before this can be discounted as a possibility we would need to have archaeomagnitudes for the same time period from many different locations, so that an accurate picture of the world-wide rate of change could be produced. The other obvious source of the fluctuations is the non-dipole field. If such non-dipole features did exist at various localities, then as they are so large they must be observable over large areas of the Earth's surface. Hence a study of archaeomagnitudes from areas separated by, say, 1,000 or 2,000 km should enable us to determine how these non-dipole features grew and decayed, and whether or not they showed the Westward drift, which is a feature of the present-day non-dipole field.

As far as the future is concerned, detailed curves of the magnitude of the Earth's magnetic field must be produced for many different areas if we are to understand the reason for the rapid fluctuations now being observed. The material used for this work must be well dated, and as Walton explains, the possibility of then using the curve produced for a given location as a dating tool would be of great help to archaeologists. However, as with all methods of archaeological dating, we must proceede slowly to ensure that the curves we use are as accurate as possible, and that as many sources of error as possible, such as the fabric anisotropy just discovered, are eliminated.

The juxtaglomerular complex: its possible control of multiple nephron functions

from Arthur C. Guyton and John E. Hall

THE discovery of a new secretory cell in the juxtaglomerular complex of the renal nephron is announced in this issue of *Nature* (page 655) by Ryan, Coghlan, and Scoggins. This cell, the granulated peripolar epithelial cell, contains large numbers of granules that are obviously secretory in nature, and it is located in the angle between the glomerular tuft and the outside wall of Bowman's capsule, at a place where its secretion passes directly into the glomerular filtrate as it is first formed at the glomerulus. The authors make the obvious observation that "it is almost inescapable that they [the cells] participate in juxtaglomerular complex [control] activity". But what is the function of these secretory cells?

The juxtaglomerular complex is an anatomical consortium of structures lying at the pole of the glomerulus. It consists of a short portion of the afferent arteriole immediately before it enters the glomerulus and similarly a short portion of the exiting efferent arteriole. And, very important, it also includes a small segment of the distal tubule that crosses the glomerular pole in the angle between the afferent and efferent arterioles and abuts against both these arterioles. This is an invariable structure of each nephron in all higher orders of animals. Obviously, this location of the complex is most propitious for it to act as a controller of nephron function, so much so that essentially every anatomist who has made contributions to its structure has referred to its possible control functions. These include Ruyter (*Ztschr. f. Zellorsch. u. mikr. Anat.* **2**, 242; 1925) who described its general structure, Goormaghtigh (*Comp. Rend. Soc. Biol., Paris* **124**, 293; 1937) who emphasised the importance of 'juxtaglomerular' myoepithelial cells in the arterial walls containing large numbers of secretory granules, McManus (*Q. Jl Micr. Sci.* **88**, 39; 1947) and Schloss (*Acta. Anat., Basel* **1**, 365; 1946) who further defined the interrelationships between the distal tubule and the vascular pole, Hartroft (*Circ. Res.* **12**, 525; 1963) who helped to determine that the secretory granules of the juxtaglomerular cells contain large quantities of renin or prerenin, and many others. In fact Schloss gave the juxtaglomerular complex the name '*der Regulationsapparat*'.

Yet, how much do we know about control of nephron function by the juxtaglomerular complex? The answer is that there has been very little proof of any control function, but on the other hand, large amounts of circumstantial evidence favour several different control functions. In 1964 (Guyton *et al. Circ. Res. (Suppl. 1)* **14**, 1; 1964), we summarised some of this circumstantial evidence and also presented a mathematical model of the manner in which feedback control signals from the distal tubule could 'autoregulate' both nephron blood flow and nephron glomerular filtration rate. Leyssac also suggested a similar mechanism (*Acta physiol. Scand.* **58**, 236; 1963). Since then, many renal physiologists have presented evidence for and against such a method for autoregulation of renal blood flow and glomerular filtration rate. After a long period in which it was disbelieved by most renal physiologists, sentiment seems to be shifting toward acceptance of such a mechanism, so much so that a new term has been coined to describe it, 'tubuloglomerular feedback'. However, there is still much disagreement over what chemical constituent or what physical factor in the distal tubular fluid is sensed to provide the feedback control of nephron blood flow and glomerular filtration.

Nephron function is also controlled by the renin–angiotensin system. At first it was thought that the renin–angiotensin system caused constriction of the afferent arterioles in response to excess sodium or chloride ions in the distal tubules (Thurau & Schnermann *Klin. Wochschr.* **43**, 410; 1965), in this way providing feedback control of the rate of flow of the sodium and chloride ions through the tubular system. However, with the advent of drugs that can block the renin–angiotensin system, we and others have been able to show that autoregulation of renal blood flow becomes better than ever when the renin–angiotensin system is blocked (Hall *et al. Am. J. Physiol.* **232**, F215; 1977). On the other hand, autoregulation of glomerular filtration is better when the renin–angiotensin system is functional. These studies have also allowed us to separate tubuloglomerular feedback into two separate components, one of which controls afferent arteriolar constriction and does not involve the renin system, yet has a strong influence on autoregulation of renal blood flow, but only a weak influence on the autoregulation of glomerular filtration. The second feedback mechanism does involve the renin system which controls the degree of vasoconstriction of the efferent arterioles. That is, when glomerular filtration is too low, feedback from the distal tubule to the juxtaglomerular cells causes renin secretion, formation of angiotensin, constriction of the efferent arteriole, elevation of glomerular pressure, and return of the glomerular filtration rate towards normal.

Thus, the efferent vasoconstrictor mechanism provides an additional quantitative dimension to glomerular filtration autoregulation, adding to the effect also provided by the afferent arteriolar mechanism.

So what control does the secretion from the newly defined peripolar cells exert. As this secretion enters directly

into the glomerular filtrate, one would suspect control of some aspect of tubular reabsorption. The obvious first question is its possible role in controlling sodium reabsorption, a subject that is still lost in a haze. But we can all think of many other nephron control functions that we would like to see it perform

Thus, the importance of the juxtaglomerular complex grows, not merely for control of a single function of the nephron but perhaps and probably as a controller of multiple functions. □

Trouble with time travel

from Paul Davies

SPECULATION about time travel has long been a source of inspiration to science fiction writers and philosophers, but anathema to physicists. Of course, time travel in a limited sense is known to be an observable fact. Ever since the inception of special relativity, with its celebrated time dilation and 'twins' effects, physicists have recognised that a sufficiently powerful rocket would enable an astronaut to travel into the future. By approaching close to the speed of light, a trip which for the astronaut occupies, say, one year, could return him to Earth to find that fifty years had elapsed there. Indeed, the disparity can theoretically be made as great as one pleases by approaching arbitrarily close to the speed of light The phenomenon is not just a conjecture. Time-travelling subatomic particles are routinely monitored in the laboratory, and the minute, but significant, time dislocations in jet aircraft, have been successfully measured. However, the trip is one way only: there is no going back into the past.

The more entertaining possibility of visiting one's own past is the one that causes physicists headaches, for it plays havoc wtih causality Suppose a time traveller kills his parents before his birth? Even signalling the past can cause horrendous paradoxes. Consider the machine that destroys itself at two o'clock if it receives a message from itself at one o'clock, sent backwards in time from three o'clock. If it blows up at two, no message goes out at three, so no explosion is ordered

It could be argued that a mass of contradictions can be avoided if one only allows a limited range of causally self-consistent loops, thus ruling out 'autocidal' machines and so on *ad hoc*. But there is no doubt that the world would be a safer place if some law of physics could be found that forbids travel into the past The trouble is that, not only do we not know of such a law, we actually do know of some circumstances where our existing theory predicts just such a possibility. The general theory of relativity, which allows space-time to be bent and distorted, describes situations in which world lines (tracks of matter through space-time) are bent right back round and can even 'close up' on themselves, that is, join up with their own past. Thus, a particle can find that its past is also its future—a collapse of causality that few are prepared to take seriously.

One situation in which general relativity seems to predict (if that is the correct word) causality violation is in the vicinity of rapidly rotating massive objects, a celebrated case being the inside of a spinning black hole. Another possibility occurs near a rotating massive cylinder (a more promising case for would-be temponauts). The experts have long regarded mathematical demonstrations of this sort as idealisations, and supposed that in reality some kind of instability would set in to prevent the causality violation occurring There is still a lack of any comprehensive theorems which will demonstrate that general relativity alone saves itself from its own causality-violating solutions, but in 1976, Frank Tipler of the University of California proved that time machines tend to go hand in hand with space-time singularities, also considered to be extremely unpalatable by physicists. So perhaps ridding the theory of singularities would also save causality.

A different possibility has recently been explored by an undergraduate student from Bristol University, now a postgraduate at King's College, London Writing in a recent issue of the *Journal of Physics* (Charlton, *J. Phys.* 11, 2207; 1978) he first investigates the topology of the two-dimensional surface which surrounds the region of spacetime in which particles possess closed timelike world lines, proving it is always a torus. He then goes on to discuss the behaviour of photons close to the time machine region. The result which he finds is that the angular momentum carried by the photon rises without limit as the conditions are approached for the existence of causality violation. In physical terms this means that any loss of radiation from the region will transport vast quantities of angular momentum away from the rotating body. The reaction back on the body itself will cause it to spin down, and hence retreat from the threat of causality violation. Thus, there seems to be an inbuilt mechanism to prevent real objects from rotating fast enough to allow time travel.

Just how general Charlton's mechanism will turn out to be is not yet clear, but it does go some way to confirm what has long been suspected—that travel into the past is purely a fiction. □

Lunar origin and palaeotides

from David W. Hughes

BEFORE the Apollo missions to the Moon there were three seriously held hypotheses for its origin. The earliest is just over a hundred years old George H. Darwin suggested in 1878 that in early times part of the Earth's crust broke away to produce the Moon, leaving the Pacific Ocean as a scar. This occurred when the Earth had already differentiated into a core and a mantle and was rotating with a period of ~ 4 h. This low spin period caused it to become oblate and unstable More recent additions to this hypothesis suggest that Mars and a myriad of smaller bodies broke away at the same time.

The second hypothesis proposes that the Moon was formed as an independent Solar System planet, further away from the Sun than Earth, and was captured by Earth about 4×10^9 yr ago.

Ring accretion is the basis of the third hypothesis. Earth once had a ring system that may have resembled that of Saturn, the planetesimals within the rings either being derived from Earth by silicate precipitation in a massive high temperature atmosphere or being the remnants of the original condensing planetesimal group that formed the Earth This ring coagulated after it had receded beyond the Roche limit.

Following N. M. Short (*Planetary Geology*, Prentice Hall, 1975) we can list some of the important lunar characteristics that the origin hypotheses have to explain The Moon is very close to being a homogeneous sphere; it has a lower density than Earth, indicating that it has lost iron; there is no water and fewer volatile and siderophile elements than both the Earth and chondritic meteorites, the Moon seems to be enriched in refractory elements, and obviously has a none too primitive composition; it was formed about 4.6×10^9 yr ago, the highland rocks being about 4.3×10^9 to 4.1×10^9 yr old, the mare basalts being about 3.7×10^9 yr old. It seems that the Moon was formed essentially at the same time as Earth and that the majority of the surface evolution took place in the

0028-0836/79/0277—0602$01.00

first 10^9 years; also there are indications that the Moon was once much closer to the Earth than it is at present.

Unfortunately none of the pre- or post-Apollo discoveries compels the unanimous acceptance or rejection of any of the three hypotheses listed above The authors of these hypotheses, to a man, have found something in the data that apparently supports their point of view. However, A J. Anderson (University of Uppsala, Sweden) is convinced that a detailed study of the figure of the Moon and the tidal forces acting on it in the past (the so-called palaeotides) indicate that the Moon could not have been formed in orbit about the Earth This would automatically rule out the ring accretion and fission hypotheses, leaving only capture. Anderson presents his case in a recent edition of *The Moon and The Planets* (**19**, 409; 1978).

The non-hydrostatic figure of the Moon arose from a distortion introduced by tidal forces some time in the past, a distortion which has been retained by the finite strength of the lunar interior. The gravity field can be charted using Doppler tracking techniques from the Orbiter spacecrafts and the Apollo command service modules that have circled the Moon. This technique led to the discovery of mascons, positive gravity anomalies that existed over certain circular lunar maria basins. These are probably thin concentrations of excess lava that have existed on the Moon for about 3.6×10^9 yr. Isostatic global readjustment has not occurred simply because the viscosity of the lunar lithosphere is of the order of 10^{27}–10^{28} poise, about five orders of magnitude greater than the Earth's

When the maria were formed by the filling of basins with low-viscosity molten lava the resulting maria surfaces would coincide with the gravitational equipotentials A careful analysis of the present-day figure of the maria surfaces gives the remnant static tidal gravity field acting at the time of solidification, and consequently the Earth–Moon distance at that time.

Anderson finds that the older lunar highlands have a smaller tidal ellipticity than the younger circular mascon maria. This is completely contrary to the supposition that the Moon was closer to the Earth when the highlands were formed than it was when the maria were formed. But we know that tidal friction does cause the Moon to recede slowly, in fact the time the Moon spends at a distance R from the Earth is proportional to R^n where n lies between 3.5 and 4.5. Anderson therefore concludes that the Moon was formed away from the Earth and was captured about 3.7×10^9 yr ago just before the time of mascon formation. There is a possibility that the lava flow which produced the mascons was actually caused by the capture. In producing this static tide solution Anderson has to assume spin-orbital coupling. This leads to the further conclusions that the mascon maria flows occurred when the Moon was between 8 and 10 Earth radii away from Earth and that before this the Moon was locked in a configuration with the Earth–Moon line about 15 degrees to the east of its present value. A remnant bulge on the lunar far side, revealed by the Apollo 16 laser altimeter, confirms the fact that just such a reorientation has occurred

So we are left with the lunar capture hypothesis, a hypothesis which unfortunately completely dissociates the origin of the Moon from the origin of the Earth and relegates the cause of their present companionship to a chance encounter during the dawn of the Solar System. If we look at other planetary satellites we can draw comfort from the fact that of the seven lunar-sized satellites, two of them (Moon and Triton) do not have orbital planes which coincide with the equatorial planes of the present planets. Considering all the satellites, about 38% are in non-equatorial orbits, in fact 19% are retrograde. It seems that satellite capture was a fairly common occurrence during the formation of the Solar System. ☐

Pathogenesis of animal trypanosomiasis

from F. E. G. Cox

ANIMAL trypanosomiasis, particularly in cattle, is a major constraint on meat production in Africa. Whether or not the presence of trypanosomiasis, which effectively prevents large scale cattle ranching throughout the tsetse fly belt, is a factor in the preservation of African soil against erosion (Ormerod *Science* **191**, 815; 1976) can be debated but there is little doubt that animals suffering from this disease are not productive and therefore constitute a considerable economic drain on the countries of Africa. Much is known about the symptoms of trypanosomiasis but little is understood of the pathogenesis of the disease and a recent meeting* brought together a number of scientists working on this and related problems.

The most important species of trypanosome causing animal trypanosomiasis are *Trypanosoma vivax*, *T. congolense* and *T. brucei* which infect cattle, sheep and goats as well as wild and laboratory animals. The pathogenic effects vary from parasite to parasite, host to host and even individual to individual. This is partly because the trypanosomes occupy different sites in the body, *T. congolense* and *T. vivax* are normally confined to the blood while *T brucei* is found in both blood and tissues, and partly because pathogenic changes may be caused by the trypanosomes themselves or by the hosts' efforts to rid themselves of their infections All three species undergo antigenic variation so in most animals there is little or no protective immunity while ineffective immune responses bring about a number of deleterious immunopathological changes.

M. Murray (ILRAD, Nairobi) suggests that the pathogenic changes during trypanosomiasis in cattle proceed in three phases; anaemia with high parasitaemia and enlarged spleen, anaemia with transient parasitaemia and variable spleen size and, in those animals that recover, anaemia without parasitaemia and the spleen returning to normal. However, dramatic changes occur within a matter of hours and many cattle die without showing major signs of disease (G. Losos, Veterinary Research Department, Muguga, Kenya) The inadequacy of the immune response is indicated by the fact that animals challenged a year after recovery usually go through the whole cycle again During infection, irreversible lesions occur and complement levels, for example, never return to normal (H. Tabel, University of Saskatchewan).

There are probably several causes of the characteristic anaemia of trypanosomiasis. There is little doubt that a haemolytic factor is involved and one possible candidate is a phospholipase associated with dying or dead trypanosomes (I. Tizard *et al.* University of Guelph). This is the first defined toxic product of a trypanosome to be implicated in the pathogenesis of trypanosomiasis and the long search for such substances, begun in the time of Landsteiner, is obviously well worth continuing There is also evidence that

---

*A Conference on Recent Advances in the Knowledge of Pathogenicity of Trypanosomes sponsored by the Canadian International Development Agency (CIDA) and International Development Research Centre (IDRC) and the International Laboratory for Research on Animal Diseases (ICRAD) was hosted by the Veterinary Research Department of the Kenya Agricultural Research Institute, Muguga and was held in Nairobi, Kenya, on 20–23 November, 1978

0028-0836/79/0277—0603$01.00

immunological responses initiated by the trypanosomes themselves are involved in red cell lysis (Tabel)

Following the initial infection, pathogenic changes occur so rapidly that it is almost impossible to unravel those that result directly from the presence of the parasites from those resulting from the hosts' attempts to compensate for damage caused by anaemia and immunological responses to parasite and possibly host antigens. Nevertheless, the disease has many of the characteristics of an inflammatory one and P F L Boreham (Imperial College, London) postulates that antibody–antigen complexes initiate a series of reactions leading to the activation of kallikrein and eventually increased capillary permeability on one hand and disseminated intravascular coagulation on the other These effects, and the anaemia, are only part of the whole pattern of pathogenesis and virtually every kind of cell (M G. Maxie & V E O. Valli, University of Guelph), tissue (W I. Morrison & M Murray, ILRAD, Nairobi) and organ (Valli) may be involved. The dynamics of the various changes can now be determined very accurately using a number of tracer and radioactive labelling techniques (J. D Dargie, FAO/IAEA, Vienna) and these techniques will become increasingly useful in the next stage of unravelling the various intertwined reactions.

No conference on trypanosomiasis could be complete without some consideration of the ways in which meat-producing animals can be kept in regions of endemic trypanosomiasis. The possibility of using cattle tolerant to trypanosomiasis is not an immediate one as carefully controlled studies have now shown that the reputed trypanotolerant breeds like the N'dama do suffer considerably from trypanosomiasis although not as much as Zebu (Murray, Dargie) but much more quantitative work is required on this subject. On the other hand, young cattle do not seem to suffer so severely from trypanosomiasis as do adults (B T. Wellde, Walter Reed Institute Washington) and eland that can be bred in captivity do seem to recover from infection (R Olubayo. Veterinary Research Laboratory, Kabete, Kenya). Perhaps we should acknowledge the supremacy of the tsetse fly at least temporarily and turn our attention to less popular breeds of cattle and alternative meat-producing animals which will eventually be able to live in Africa together with the tsetse fly and the trypanosomes but in the absence of clinical trypanosomiasis. ☐

Pacific quiet zone contracted

from Peter J. Smith

LARGE-amplitude linear magnetic anomalies have now been used to interpret vast areas of the Earth's ocean floor in terms of plate tectonic processes But there are still gaps; there are still difficulties in some areas, not least in the western Pacific. The late Mesozoic pattern of magnetic lineations in this region was first unravelled by Larson and Chace (*Geol. Soc Am. Bull.*, **83**, 3627; 1972) who traced seafloor spreading back to the early Cretaceous and later to 153 million years (see, for example, Larson & Hilde *J. geophys Res.*, **80**, 2586; 1975). But beyond that, in both temporal and geographical senses, there is a large zone of low-amplitude $(<100\gamma)$ anomalies, known as the Pacific Jurassic quiet zone (PJQZ), surrounding the Mariana Basin.

Whatever the cause of the PJQZ, its existence has impeded the resolution of the area's tectonic history and may have led to unnecessarily forced interpretations. For example, Hilde *et al* (*Tectonophys.*, **38**, 145; 1977) suggested that the Mariana Basin may be underlain by Cretaceous crust formed during the better-documented Cretaceous magnetically quiet period—a proposal which implies, of course, that the basin originated during a time of intraplate spreading about 100 million years ago In other words, by this interpretation, the magnetic anomalies in the western Pacific get older and older until they reach the PJQZ boundary at 153 million years, beyond which the lithosphere is younger

This is possible, but unlikely. Moreover, as Cande *et al.* now suggest (*Earth planet. Sci Lett.* **41**, 434; 1978), such contorted theorising is unnecessary. Cande and his colleagues show (from existing data) that in the PJQZ, immediately beyond the 153 million year line, the magnetic anomalies are apparently no different in character and lineation, but differ only in amplitude, from those on the younger side of the line. It is necessary to say 'apparently' here because it is just possible that the older alternating positive and negative anomalies are not the result of field reversal at all but of field magnitude fluctuations within a single polarity; and certainly the observed anomalies may be modelled successfully on either assumption. But just as there is no doubt that the anomalies younger than 153 million years are produced by a combination of seafloor spreading and geomagnetic field reversal, there is little reason to suspect that the older anomalies are not produced likewise Cande *et al.* have thus been able to extend the Mesozoic polarity-time scale, temporally, about 5 million years beyond the previous limit of 153 million years and geographically closer in towards the Mariana Basin from three different directions.

On this basis the field reversal rate during those 5 million years within the PJQZ was calculated to be once about every 100,000 years. But if the 153 million year boundary has no significance in terms of field reversal, seafloor spreading and the shape of the resultant magnetic anomalies, why is there a PJQZ at all? The first thing to be said about this is that the PJQZ boundary is not as sharp as it is sometimes imagined; there is no sudden change in anomaly amplitude at 153 million years. In fact, the amplitude begins to decrease somewhere around 140 million years and continues to do so fairly smoothly up to 155–160 million years. Or to rephrase this in forward time terms, from 160 to 140 million years ago the anomaly amplitude in the western Pacific increased fairly smoothly, actually by a factor of about four

This increase in amplitude could have been due to a real increase in the magnitude of the geomagnetic dipole moment. Alternatively, it could have been the result of a gradual decrease in the frequency of (undetected) short polarity events, the presence of which would give an apparent reduction in the amplitudes of the observed anomalies. On the basis of the small-scale magnetic detail observed in the profiles from the faster-spreading sections of the western Pacific, Cande and his colleagues conclude that the first of these explanations is the most likely Either way, the field of uncertainty in the western Pacific has been reduced, and in such a way as to suggest that further reduction may soon be possible ☐

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University

A hundred years ago

AT the last meeting of the French Geographical Society a letter was read from the Abbé Desgodins, dated Yerkalo, August 27, 1878, in which he states that, contrary to the common assertion which represents the sheep as the beast of burden most used in Thibet, this function belongs in preference to the yak (*Bos grussiens*); the the mule, ass, and horse are also made use of.

Laser isotope separation

V. S. Letokhov

Institute of Spectroscopy, USSR Academy of Science, Moscow, Podol'skii rayon, Troitzk, 142092, USSR

It is about 10 years since new methods of isotope separation by means of laser radiation were first proposed. In the past five years a lot of effort has been put into elaborating and realising these techniques. Now we are at the threshold of demonstrating the first pilot set-ups of laser isotope separation (LIS). In this review I will try to outline the basic ideas, methods and key experiments.

THE successful elaboration of LIS methods at the beginning of the 1970s became possible only because of the development of a variety of tunable lasers covering a wide spectral range from about 2,000 Å to 20 μm. Moreover, LIS methods pose stringent requirements for the parameters of tunable lasers and thus stimulate additional research into the development of highly efficient tunable lasers. (For more detailed reviews see refs 1-5.)

Ideas and various LIS methods

All LIS methods are based on a series of consecutive processes which start with the selective photo-excitation of an atom or a molecule of the chosen isotopic composition. Isotopically selective photoexcitation is possible because of the difference of frequencies and structure of spectral absorption lines of atoms and molecules of different isotopic composition[6,7]. Isotopic effects appear in optical atomic spectra due to the difference of masses, volumes and nuclear spins of different isotopes[8,9]. The difference in isotope mass which affects the frequency of vibrations and rotations of a molecule is essential for molecular spectra[10–12]. Spectral lines in a gas of low pressure (less than a few torr) are very narrow, so that a small isotopic shift is sufficient for selective excitation of the chosen isotope. However, there are some important exceptions (atomic spectra of alkaline and alkaline-earth elements, spectra of polyatomic molecules with heavy isotopes at room temperature) for which special methods of narrowing of spectral lines (atomic beams[13]) and of simplification of complex molecular spectra (cooling of molecules in a gas or in a supersonic jet[14–16]) are applied. Broadened spectral lines of molecules in a gas at a pressure of more than a few torr and in a condensed medium are not appropriate with rare exceptions (low temperature matrices[17]) for isotopically selective excitation.

The excitation of an atom (molecule) changes some of its physical and chemical properties (Fig. 1) noticeably. First, the excited atom (molecule) usually has a higher chemical reactivity than the unexcited one, as the acquired internal energy increases the probability of overcoming the energy barrier of a chemical reaction. The photochemical approach to isotope separation is based on the ability of selectively photoexcited atoms (molecules) to react chemically with a suitable partner at a rate considerably exceeding the rate of chemical reaction of unexcited atoms (molecules) of another isotopic composition. This approach is well known and was successfully used in the photoexcitation of electronic states of some atoms and molecules before lasers were invented[18–24].

Second, the excitation of an atom markedly decreases its ionisation energy and hence selectively excited atoms can be ionised by additional radiation of a suitable wavelength, leaving unexcited atoms of different isotopic composition untouched. This idea forms the basis of the atomic photoionisation approach to LIS.[25–27]

Third, the excitation of a molecule reduces its dissociation energy quite significantly and hence selectively excited molecules can be dissociated much more easily than unexcited molecules of another isotopic species. This mechanism is the basis of the first photodissociation methods of LIS developed[27–29].

These three main ideas are the basis of the fundamental actively developed trends (photochemistry, photoionisation and photodissociation) in LIS considered here. Several other less universal, but also interesting, methods of LIS use photopredissociation[30,31] and photoisomerisation[32] of some molecules, and photodeflection of the atomic trajectory at photon absorption due to the recoil effect[33]; other methods are also proposed and demonstrated.

Photoionisation methods

Selective photoionisation of atoms is the most universal photophysical method for selective separation of substances, particularly isotopes, at the atomic level. A feature common to all

schemes for selective ionisation, is the sequence of the two steps: (1) isotopically selective excitation and (2) ionisation of the excited atoms. Figure 2 shows the main schemes of selective atomic ionisation of special interest for LIS. The two-step photoionisation scheme[23–27] is the simplest. The three-step scheme may be useful for ionisation of atoms with a high ionisation potential using visible lasers. The photoionisation cross-section can be increased by tuning the frequency of the last-step radiation to that of a transition to an autoionisation state: either a spontaneous[34] or an electric field-induced[35] state. Finally, high Rydberg states can be ionised by IR radiation[36] or pulsed electric fields[35]. All these schemes have already been used for isotopically selective ionisation. Their advantages and disadvantages are not discussed here but detailed information is given in ref. 37.

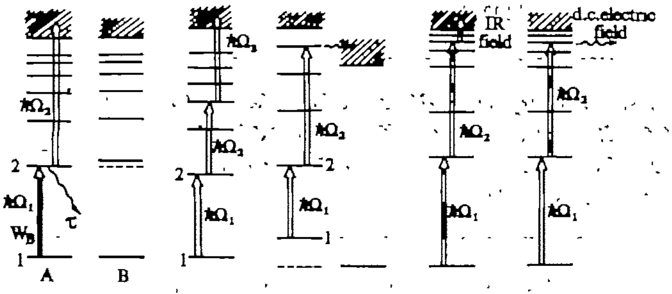

Fig. 2 Mechanisms of isotopically selective step-wise photoionisations of atoms by laser radiation; *a*, two-step photoionisation, *b*, three-step photoionisation; *c*, stepwise photoionisation through an autoionisation state; *d*, selective excitation of a Rydberg state and its photoionisation by IR laser radiation; *e*, selective excitation of a Rydberg state and its ionisation by electric field.

A great deal of attention has been paid to uranium isotope separation (some research programmes are described in refs 38–42). At low density of uranium vapour in an atomic beam (10^{10} cm^{-3}), a 70% isotope enrichment of ^{235}U uranium ions has been obtained as a result of selective two- or three-step ionisation of ^{235}U atoms by dye laser radiation. As the abundance of ^{235}U in natural uranium is only about 0.7%, such an enrichment corresponds to an isotope separation factor of about 100. The operating conditions of the LIS set-up at such low vapour density in the atomic beam are far from optimal and in order to obtain the necessary production capacity and high efficiency of the applied laser radiation the size of the equipment should be very large. Similar experiments at higher density of uranium vapour (10^{13} atoms cm^{-3}) have yielded 6% enriched ^{235}U (ref. 42). This indicates that this process is well adapted to produce light-water reactor fuel but less suitable for highly enriched uranium. The considerable technical problems of such a method of uranium LIS, for instance, the high chemical reactivity of uranium vapour at the high temperatures necessary to produce the required density should also be kept in mind. Therefore there are some problems in industrialising the atomic ionisation process of uranium LIS. But the suggestion that such a process will lead to the cheap production of highly enriched uranium in moderate-size laboratories, is somewhat exaggerated[43].

Besides the uranium isotope separation, which demands rather different economic technological conditions, laboratory experiments are being carried out on the selective ionisation of other isotopes, which are potentially useful in much smaller quantities, such as Ca (ref. 13), Rb (ref. 44), rare-earth[45], and probably transuranium elements. Effective ionisation of excited atoms at a moderate average intensity of the ionising laser radiation, on laboratory LIS set-ups presents a major problem in these cases. The ionisation schemes given in Fig. 2*a,b* cannot be practically applied here, and so greater attention must be paid to the ionisation scheme of highly excited atoms shown in Fig. 2*d,c*. The ionisation of high-lying states by an electrical field pulse[35,44,46] is the most simple and universally applied method. This method of stepwise ionisation has been reported in detail elsewhere[46–50] for various atoms.

The discovery of a long-lived (~1 ns) autoionisation state in the spectrum of Gd atoms[51] with its large transition cross-section of 10^{-15} cm^2 shows that such a scheme can sometimes compete with the scheme which uses the electrical pulse for ionisation of a highly excited atom.

The method of multi-step selective ionisation of atoms through the high-lying sharp quantum states in the vicinity (below or sometimes above) of the ionisation limit is quite suitable for LIS, at least on a laboratory scale.

Photodissociation methods

Various schemes of isotopically selective photodissociation of molecules through the excited and/or the ground electronic state are shown in Fig. 3. These were first proposed, experimentally realised and used for isotope separation at the Institute of Spectroscopy of the Academy of Sciences of the USSR. They are now widely used both for LIS and for potential applications in photochemistry, phototechnology of materials, and most recently, in photobiology.

All these schemes are based on primary isotopically selective excitation of vibrational states of molecules by IR laser radiation as long as the vibrational spectra have considerable isotopic shifts (especially for light elements). In the simplest case (Fig. 3*a*) the molecules excited to the first vibrational level can be dissociated by irradiation of an appropriate wavelength[28,29] following the excitation of the unstable electronic state. The first successful experiments on isotope separation using two-step (IR+UV) molecular photodissociation were carried out on molecules of ^{14}NH$_3$ and ^{15}NH$_3$ (refs 29, 52) and the corresponding experiments on molecules of ^{10}BCl$_3$ and ^{11}BCl$_3$ were carried out[53] later.

The disadvantage of such a method is the comparatively small redshift of the UV photodissociation absorption band after excitation of a molecule to the first vibrational level. This limits the isotopic selectivity of IR+UV dissociation. This disadvantage disappears when exciting higher vibrational levels due to the multi-step or multi-photon process (Fig. 3*b*). This has recently been shown in experiments[54] with ^{12}CF$_3$I and ^{13}CF$_3$I molecules using an IR CO$_2$ laser and UV excimer laser, where the dissociation selectivity has been found to be >100.

An impressive and productive discovery was the isotopically selective photodissociation of polyatomic molecules BCl$_3$[55], SF$_6$[56]) by intense IR CO$_2$ laser radiation. The discovery of this effect was preceded by studies[57–61] of the interaction of intense IR CO$_2$ laser pulses with molecular gases absorbing in the region of 10 μm. It was found that under relatively intense IR radiation during a short time (10^{-7}–10^{-9} s), a polyatomic molecule could pass through the vibrational levels reaching even the dissociation limit (Fig. 3*c*), without colliding with other molecules. The whole process of multiple absorption of IR photons begins

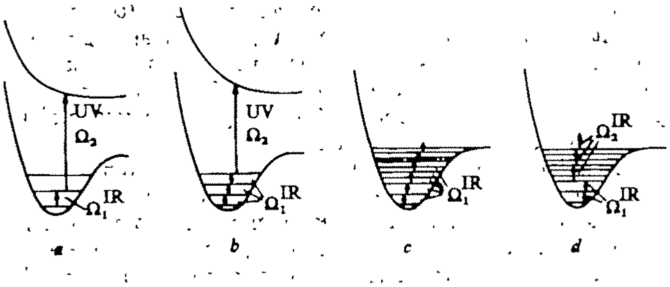

Fig. 3 Schemes of isotopically selective multi-step photodissociation of molecules by laser radiation through an excited electronic state (*a*, *b*) and the electronic ground state (*c*, *d*): *a*, two-step IR+UV photodissociation; *b*, multi-selective excitation of high vibrational levels and their photodissociation by UV radiation; *c*, multiple photon selective excitation and dissociation by a single frequency intense IR field; *d*, multiple photon selective excitation of vibrational levels by resonant IR field and their multi-photon dissociation by non-resonant intense IR field.

with a low vibrational transition where there is usually a marked isotopic shift (at least for isotopes of light and moderate masses). By choosing an appropriate IR-radiation frequency the dissociation of some isotopic molecules can be achieved. The case of isotopic SF_6 molecules is shown in Fig. 4. When the frequency of powerful pulsed CO_2 laser radiation with pulse energy of several J cm^{-2} is tuned to the absorption frequency of the chosen isotopic molecule, preferential photodecomposition takes place. This is demonstrated by the change of the isotopic composition (enrichment) of the undissociated SF_6 molecules and of products formed as a result of dissociation.

Much information about isotope separation by dissociation has been obtained using multiple photon absorption of IR radiation for a large number of polyatomic molecules, including BCl_3 (refs 55, 62, 63), SF_6 (refs 56, 64, 65), OsO_4 (ref. 66), CCl_4 (ref. 67), SiF_4 (ref. 63), $C_2F_2Cl_2$ (ref. 63), CH_3NO_2 (ref. 68), MoF_6 (ref. 69), $H_2Cl_2C_2$ (ref. 70), H_2CO (ref. 71), SeF_6 (ref. 72), CF_3I (refs 73, 74). The dissociation of SF_6 molecules, in particular, has been widely investigated. A detailed description of the method of multi-photon IR laser photochemistry is given in refs 4, 5, 75.

The abundance of vibrational–rotational transitions in a polyatomic molecule (which increases sharply after absorption of several IR photons) is the main reason for this ready absorption of many photons up to the dissociation limit. There is no such multiple absorption of IR photons in simple (two- or three-atomic) molecules where the number of possible vibrational–rotational transitions is limited. An excited polyatomic molecule absorbs IR photons by many different vibrations which leads to a strong excitation of a large number of (perhaps all) vibrational degrees of freedom. In this case the high vibrational temperature can be assigned to the excited molecules (thermal model[75,76]), and its dissociation can be described by the well known theories of monomolecular reactions[77].

An important modification of this method is the scheme shown in Fig. 3*d*, when dissociation is carried out by two pulses of IR radiation at different frequencies[78]. In this way it is possible to separate the functions of isotopically-selective excitation of a molecule and the dissociation of selectively excited molecules. For selective excitation of a molecule, radiation of a finely tuned frequency ω_1 and intensity is required. Dissociation of selectively excited molecules requires intense radiation of only roughly controllable frequency ω_2. In this case, isotopic selectivity of dissociation is enhanced as strong non-resonant radiation at frequency ω_2 does not perturb the resonant transition at frequency ω_1. This method is particularly important for isotope separation of heavy elements. Recent experiments[79] on OsO_4 molecules have shown that it is possible to obtain a separation selectivity of about 1.6 using two-frequency dissociation, provided all the parameters are chosen correctly; for one-frequency dissociation, however, when a natural mixture of isotopic molecules is irradiated, no isotopic selectivity is obtained.

Recent experiments[80,81] on multi-photon dissociation of UF_6 molecules by 16 μm radiation pulses of a CF_4-laser, that is at the frequency of the vibrational band ν_3 of UF_6, were carried out according to the simplest scheme of dissociation in a single frequency IR field (Fig. 3*c*). Dissociation characteristics (threshold energy, yield) resemble in many respects the corresponding characteristics for SF_6. The next obvious step is to obtain the required dissociation selectivity (about 4) using the more delicate schemes of dissociation shown in Fig. 3*b,d*. A more reliable way of increasing the UF_6 dissociation selectivity is to use dynamically cooled UF_6 to provide distinct resolution of vibrational–rotational absorption lines of $^{235}UF_6$ and $^{238}UF_6$ (ref. 83).

Photochemical methods

So far, the possibilities of photochemical isotope separation have been shown by using the excitation of atomic and molecular electronic states and of molecular vibrational levels. However, in spite of the optimism of the early research, the actual advances made seem much less impressive than for the photophysical (photoionisation and photodissociation) methods discussed above.

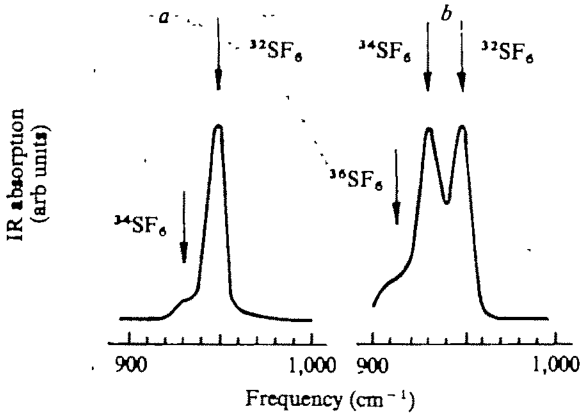

Fig. 4 The infrared spectra of SF_6 before (*a*) and after (*b*) irradiation by focused pulses of TEA CO_2 laser. The number of laser shots was chosen so as to equalise the concentrations of $^{34}SF_6$ and $^{36}SF_6$ (ref. 56).

The chemical reactions of electronically excited atoms and molecules have been studied for many years—especially before the application of lasers. The photochemical isotope separation of Hg excited by the 253.7-nm resonance line has been successfully demonstrated with a variety of reagents[18–24]. For example, Pertel and Gunning[23] were able to enrich ^{202}Hg from 30% of its natural abundance to 85%. The kinetics of the photochemical reactions of Hg are so complex that even the most extensive work does not yield a complete mechanism. Successful experiments on isotopic separation of nitrogen[84] (or resonance lamp for excitation of NO) and carbon[85] (iodine resonance lamp for excitation of CO) have subsequently been carried out. An enrichment factor of ~4–6 has been achieved.

Laser sources for photochemical isotope separation have many obvious advantages over incoherent sources. The broad tunability and high ultimate resolution of lasers give a comparatively free choice of absorption lines, while permitting the highest possible selectivity. This makes the process of photochemical separation of isotopes much easier. It is basically impossible to carry out photophysical experiments of LIS with the usual noncoherent sources of light, because their low radiation temperature means they cannot sufficiently populate the intermediate quantum states and hence cannot provide the effective multi-step process of excitation.

Several successful experiments on laser photochemical enrichment have been reported. The most interesting results have been obtained in experiments on photochemical separation of ^{35}Cl and ^{37}Cl through isotopically selective electron excitation of ICl molecules by cw dye laser radiation[86–88]. For example, in the case of selective photo-addition of ICl to acetylene, an enrichment factor of ^{37}Cl of 100 was obtained[88], in the photoproduct C_2H_2ICl. Both stable chlorine isotopes can be enriched to more than 97% purity in a single step, starting from natural samples. This is a most promising result in isotopically selective electronic photochemistry.

The rate of a chemical reaction may be substantially enhanced by vibrational excitation of the reactant molecules, and it was suggested as a method for LIS in 1963 (ref. 89). However, the first successful experiment was not until 10 years later[90] when ^{35}Cl was enriched by enhancing the reaction of Br atoms with vibrationally excited $H^{35}Cl$. An HCl-pulsed chemical laser was used to excite HCl from $\nu = 0$ to $\nu = 1$ and to $\nu = 2$. For equal pressures of Br and HCl a separation factor of 2 was observed. Recently, carbon isotopic enrichment was also observed in the reaction of vibrationally excited CH_3F molecules with bromine atoms[91]. Although the observed enrichment factor was small, this experiment is interesting from the point of view of using a cw IR laser for LIS.

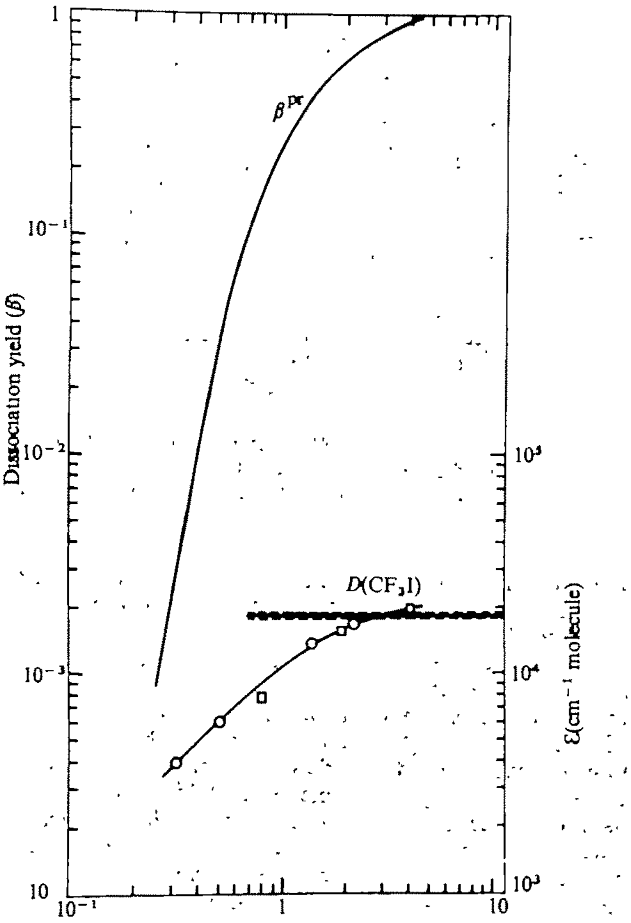

Fig. 5 The dependence of the average energy $\bar{\varepsilon}$ absorbed by CF_3I molecule (curve 1, right scale) and of the primary dissociation yield at 0.2 torr CF_3I (curve 2, left scale) on the energy of the CO_2 laser pulse[74].

Pumping of BCl_3 molecules in a mixture of BCl_3+H_2S (or D_2S) by a focused, pulsed CO_2 laser, which probably excites high vibrational levels, caused separation of boron isotopes[92]. Clearly this experiment is intermediate between single-photon IR photochemistry in a weak field[89–91] and multiple photon IR photochemistry in an intense field[55,56].

Potential advantages of LIS

The laser method of isotope separation has several potential advantages over the more traditional methods (see ref. 93).

(1) High selectivity of elementary processes of separation. The separation selectivity on one stage α in most traditional methods is very small: $\alpha - 1 \ll 1$. Therefore, many stages of separation N are needed to obtain a high enrichment factor $K = \alpha^N \gg 1$. Laser methods provide $\alpha \gg 1$, which reduces the number of separation stages in most cases to only one or two.

(2) Possibility of extracting the desired isotope leaving other isotopes untouched. When the element has a few isotopes with intermediate masses, we can extract only the desired isotope using a tunable laser leaving other isotopes untouched. This is of particular importance when enriching rare and/or intermediate isotopes.

(3) Low energy consumption. LIS methods consume $\sim 10^2$–10^3 eV per separated atom (at 1–10% laser efficiency). Energy consumption per separated atom in most traditional methods is 10–10^4 times higher.

(4) Short starting time. Steady-state operating conditions for most laser methods are achieved immediately. The starting period for traditional methods can be at least several months.

(5) Possibility of running remote separation process using only laser radiation. The absence of traditional separating elements in laser methods leads to minimal contact of the enrichment material with the equipment surfaces, and hence to minimal contamination. This is particularly important for the separation of radioactive isotopes and for the management of radioactive waste of nuclear reactors.

(6) Universality. The efficiency of most traditional methods depends on the mass of the product enriched. Most laser methods can be used with almost equal efficiency for isotope separation of any element, whether light or heavy.

Experiments on a practical scale

However, not all laboratory-scale LIS methods are promising for industrial isotope separation. For industrial scaling the method should have at least two features: first, generation of laser radiation at a power level ranging from 1 kW to 1 MW (depending on the required productivity of the separation set-up). Second, laser equipment which is economical and sufficiently reliable during use.

These two requirements limit the number of LIS experiments that can be carried out on an industrial scale using existing lasers. From this point of view the most promising method is based on isotopically selective dissociation of polyatomic molecules in an intense IR field. The simplest and inexpensive gas flow TEA CO_2 lasers, with total efficiency of 5–10% and average power of up to 1 kW may be used. Initial experiments[94] on isotope separation with a pulsed CO_2 laser of average power (up to 1 kW) and high repetition rate (up to 180 Hz) have shown that comparatively high isotopic selectivity of dissociation can be obtained in these conditions.

Furthermore recent experiments[74,95] with CF_3I show that the following theoretical parameters of multi-photon isotopically selective dissociation can be realised: (1) minimum energy consumption equal to the dissociation energy of the weakest molecular bond (2 eV); (2) ultimate (almost 100%) dissociation yield of molecules in the irradiated volume at moderate energy flux of IR radiation; (3) high selectivity of dissociation >30) at comparatively high (5–10 torr) total pressure of gas; (4) significant extraction (about 50%) of the chosen rare isotope (^{13}C) without substantial decomposition (<2%) of the remaining molecules ($^{12}CF_3I$); (5) elimination of secondary photochemical processes which could destroy the high selectivity of primary dissociation. The key characteristics of multi-photon dissociation of CF_3I molecules, which are most important for carbon isotopic separation on a practical scale, are shown in Fig. 5, which shows the dependence of the primary dissociation yield of CF_3I molecules on the energy of the CO_2-laser pulse, as well as dependence of the average energy $\bar{\varepsilon}$ absorbed by the CF_3I molecule on the radiation energy. Clearly when the absorbed energy $\bar{\varepsilon}$ is greater than the dissociation energy D, almost all the CF_3I molecules are dissociated.

These results show the potential of the development of an installation for isotope separation based on a CO_2 laser. The simplicity and technological advantages of the LIS method will ensure its early industrial application.

Isotopes for nuclear energy

The isotopic enrichment of ^{235}U for power generation in nuclear reactors is the most economically important objective of LIS. World fuel requirements for nuclear reactors between now and the year 2000 are estimated to be $\sim$6 M tons of U_3O_8. Enrichment cost estimates for processing this ore amount to $\sim$150 billion US $ (refs 3, 96). An efficient laser enrichment scheme could cut these costs dramatically. Several laboratories are therefore experimenting with various schemes for LIS of uranium. As mentioned above, both the atomic process of uranium LIS[38–42] based on photoionisation and the molecular process based on photodissociation of UF_6 molecules[80–83] are being investigated very extensively.

Large quantities of D_2O are needed for heavy water nuclear reactors, which can use natural uranium fuel. The current world

production capacity is $>10^3$ ton yr^{-1}. The 800 tons of D_2O required for a 1 GW power reactor cost ~\$100 m and account for 15–20% of the total capital cost. Canadian engineers estimate that they will need more than 4×10^3 ton yr^{-1} for their reactors[97]. This means that new effective methods of hydrogen isotope separation must be found. However, it should be kept in mind that as the present production costs per atom of D are 1,000 times less than those for ^{235}U, it will be much more difficult to develop an economically viable process for D. The very low content of deuterium (1/5,000) in natural water demands rather high separation selectivity (~1,000) for economical LIS, that is several hundred times more than for uranium. Nevertheless, the possibility of hydrogen LIS by photopredissociation of HDCO using tunable UV laser radiation[97–99], and by multi-photon dissociation of polyatomic molecules by CO_2 IR laser radiation[100] is under investigation.

In the future we must also consider applying LIS methods to produce monoisotopic materials of isotopes with low-neutron capture cross-section for instance titanium isotope separation[101].

Conclusion

It would be difficult to compare in detail the different methods of laser isotope separation without considering specific isotopes or classes of isotopes. Comparison of the methods under development with those already existing is especially complicated. Laser methods are clearly better for separating isotopes that cannot be satisfactorily separated by existing methods, that is less abundant isotopes and the transuranium elements. Major technological progress in the separation of many stable isotopes in comparatively moderate quantities seems to be imminent. In the case of isotopes needed in large quantities for nuclear energy (uranium, deuterium), the situation is still somewhat uncertain. When comparing separation methods for specific isotopes we must keep in mind the level of existing laser technology. In all cases the development of large scale LIS is limited by the energy of present lasers. We need average laser powers within 10^3–10^4 W to produce only 1 ton yr^{-1}. In fact, progress in laser technology may change the situation rather drastically. An accurate prediction of the most feasible method of future large-scale laser separation of isotopes cannot be made with certainty given the present state of laser technology.

It is appropriate to emphasise that the selective photophysical and photochemical methods for laser isotope separation will find fundamental and practical application well outside the isotope separation problem. With laser radiation it is possible to use various photoprocesses (separation, chemical reactions, detection of atoms, molecules and molecular bonds) selectively in substances at atomic–molecular level with respect to various chemical elements, isotopes, nuclear isomers, molecular stereoisomers, *ortho-* and *para*-molecules, and so on[102–104]. We are essentially dealing with a new approach to the technology of materials at the atomic and molecular level when one can use laser radiation to manipulate atoms and molecules of a particular type directly—one can collect macroscopic amounts of matter 'atom by atom' and 'molecule by molecule'.

Besides selective chemical reactions and selective separation of substances at the atomic–molecular level, the process of selective detection of atoms, molecules and molecular bonds is very important. The various processes of selective laser photophysics and photochemistry are summarised in Fig. 6. Isotopically selective photophysical and photochemical processes are currently progressing very rapidly; these and their less evident applications are reviewed in ref. 104. Selective laser photoprocesses open new possibilities to related subjects, such as nuclear physics, spectroscopy, molecular biology, chemical technology and biochemistry. Some of these processes, such as laser identification of nucleotide sequences in DNA, and laser selective biochemical processes are becoming as important as isotope separation by lasers.

VLBI observations of hot spots in the lobes of distant radio sources

V. K. Kapahi* & R. T. Schilizzi

Netherlands Foundation for Radio Astronomy, Dwingeloo, The Netherlands

In a VLBI experiment, using the Westerbork synthesis radio telescope as a total power array and the Effelsberg 100-m dish, 'hot spots' with sizes ≲0.15" have been detected in the lobes of several 3CR radio sources of high redshift. The individual lobes of double sources and the hot spots within them may have been smaller at earlier epochs.

MOST powerful extragalactic radio sources with normal radio spectra consist of two extended lobes of emission more or less symmetrically disposed with respect to the parent galaxy or quasar. Often there is also a weak compact component coincident with the optical object. In several cases high resolution observations have indicated the presence of one or more regions of enhanced surface brightness, usually near the outer edges of the radio lobes. It is generally agreed that such 'hot spots' represent regions where radio-emitting electrons are accelerated and supplied to the extended regions of the radio lobes, and several different theories have been put forward to

explain their origin (for example, regions where beams of relativistic particles or low-frequency electromagnetic waves impinge on the intergalactic medium[1]; regions of plasma turbulence[2]; or supermassive objects ejected from the nucleus[3,4]). Detailed studies of hot spots are clearly important for an understanding of the evolution of radio sources.

Previous investigations of the statistical properties of hot spots in 3CR sources have been carried out using the techniques of aperture synthesis and of interplanetary scintillations (IPS). From synthesis observations at 5 GHz it has been reported[5] that the fractional source intensity contributed by hot spots correlates well with total source luminosity at 178 MHz, such that hot spots account for nearly all the emission in the most luminous sources. Observations of IPS at 81.5 MHz indicate[6] that the physical sizes of hot spots may increase with increasing source luminosity. But because of the strong correlation between luminosity and redshift in the 3CR sample, the properties of hot spots noted above correlate as well with redshift as with luminosity, and if the physical sizes of hot spots do not change with redshift the IPS results can also be interpreted to imply[7] a value of q_0, the deceleration parameter, in the range $0.5<q_0<2$. However, the properties ascribed to hot spots in sources at low and high redshifts may not always refer to similar physical features in their brightness distributions[8]. This is particularly true if the individual lobes of radio sources were physically smaller at earlier epochs. As the lobes of many radio sources at high redshifts ($z\gtrsim 0.5$) are often only 1 or 2 arcs in angular extent the existing aperture synthesis and IPS observations cannot indicate whether the observed components are true hot spots without any extended lobes around them or whether they have finer structure in them attributable to hot spots. Angular resolution considerably better than 1 arc s is therefore necessary to answer this important question.

We report here observations of the lobes of high luminosity 3CR sources carried out with a very-long-baseline interferometer (VLBI) system using the Westerbork synthesis array and the Effelsberg 100-m antenna. Compact components containing significant fractions of the total flux densities in sizes ≤ 0.15 arc s have been detected in the lobes of several radio sources of large redshift. These compact components have luminosities comparable to those of hot spots in nearby sources of similar total luminosity. There is, however, some indication that the physical sizes of these hot spots may have been smaller at earlier epochs, contrary to the inference drawn from the IPS results.

The source sample

A total of 35 radio sources was observed. This included 27 quasars: all those (except 3C191 and 3C207) in the 3CR sample of 200[9] that have (1) redshift $z>0.5$; (2) radio spectral index $\alpha<-0.5$ (defined as $S\propto\nu^{\alpha}$) throughout the frequency range of 80–5,000 MHz; and (3) no known low-frequency cut-off down to 38 MHz. The other eight sources observed were galaxies satisfying the above criteria, with the redshift estimated in most cases from the optical magnitudes. The sources have a luminosity $\geq 9\times10^{26}$ $\mathrm{WHz^{-1}\,sr^{-1}}$ at 178 MHz and nearly all of them are known to be standard double sources with component separations >1 arc s.

The interferometer system

The Effelsberg 100-m telescope and the 1.6-km Westerbork synthesis radio telescope used in total power mode formed the elements of the VLB interferometer for these observations at 1,417 MHz (see Table 1). The observations took place between 15.00 UT on 31 March and 15.00 UT on 2 April in 1978. The polarisation was linear in PA 0° on the sky.

Total power operation at Westerbork was achieved by coherently adding the signals from the Y dipoles of the 14 telescopes in the array after IF conversion to baseband. The added baseband signal was fed directly to the format unit of the VLBI recording terminal. A full description of the adding system is given elsewhere[10]. Steering of the telescope in delay and fringe rate (after phase offsets for the individual telescopes had been determined) was carried out in the last IF stage—the normal mode of operation for the Westerbork telescope. The fringe stopping centre, the delay centre, and the centre of the fan beam were identical on the sky. The orientation and half-power width of the fan beam are functions of the hour angle and declination of the source; at zenith on the meridian the beam width is 22 arc s east–west and 22 arc min north–south.

Table 1 Elements of the interferometer

	Antenna diameter (m)	System temperature at zenith (K)	Sensitivity (K Jy^{-1})
Effelsberg	100	75	1.5
Westerbork	93*	85	1.4

*Equivalent diameter; the Westerbork array has 14 dishes each of diameter 25 m.

Up to four short observations, each of ~10 m duration were made for each source at different hour angles within the ±6 h range at Westerbork. Observations of calibrators were interspersed at regular intervals throughout the period. In cases where the width and orientation of the Westerbork fan beam encompassed both lobes of the source, a single observation of the whole source was made. In other cases observations of each lobe were made independently.

The Effelsberg–Westerbork interferometer is 1.26 Mλ in length at the observing frequency, giving a fringe spacing of ~0.16 arc s. The length of the baseline changes very little with hour angle, but the orientation changes considerably, allowing one to say whether any particular source is non-circular in structure.

The recording of the signals was carried out with the standard Mk IIC VLBI system with a bandwidth of 2 MHz and the subsequent cross correlations and data reduction were done at the Max Planck Institute for Radio Astronomy. A hydrogen maser oscillator at Effelsberg and a rubidium oscillator at Westerbork provided the time and frequency standards.

Calibration of the data

The correlated flux density scale was calibrated using the sources NRAO140, 4C39.25, OQ208, 3C345 and 3C454.3. Table 3 lists the calibrator sources, the number of times they were observed, the total flux density as measured at Effelsberg during the observations and the flux density in compact components. In NRAO140 and OQ208 the compact components supply the total flux density. Measurements of the larger scale structure in 3C345 and 3C454.3 by Davies *et al.*[11] were used to remove the contribution of these steep-spectrum resolved components to the total flux density. Available spectral information on 4C39.25 was used to remove the contribution of a steep-spectrum component. The calibration factor for all five sources has an r.m.s. scatter of ~6%. Removing OQ208 reduces the r.m.s. scatter to ~2%; this implies that the measured flux for OQ208 may be too low. The measured r.m.s. scatter in amplitude from one scan to another for the individual calibrators is ~4%.

Checks on the calibrator sources indicated that there was no loss in fringe amplitude due to phase drifts in the oscillators (primarily the rubidium) on time scales of 10 m. Consequently,

Table 2 Geocentric coordinates of the observatories

Observatory	X (km)	Y (km)	Z (km)
Effelsberg	4,033.778	−486.995	4,900.529
Westerbork	3,828.674	−443 226	5,064.916

The X-axis points to latitude 0°, longitude 0°; the Y axis to latitude 0°, longitude 90°; and the Z axis to latitude 90°

each observation on the extended sources was integrated coherently for the duration of the observation, typically 10 m. The r.m.s. noise in correlated flux density for a 10 m coherent integration was observed to be 3 to 4 mJy, allowing reliable detections of compact components as weak as 15 to 20 mJy.

The X and Y components of the baseline were determined by least-squares fitting to the fringe rates for the calibrators, and a crude estimate of the Z component was made from the delay function corresponding to the 2 MHz recorded bandwidth. The X, Y, Z parameters of the individual telescopes are given in Table 2. The r.m.s. scatter in the fringe rates of the calibrators about zero residual fringe rate is ±1 mHz assuming the best fit baseline. This means that the pointing of the beam centre is known to that accuracy in the fringe rate variable. This is sufficient to distinguish, in many of the sources observed, between a compact component at the centre of the beam and one in an outer lobe.

The width and orientation of the Westerbork beam were calculated for each observation. In cases where components were detected away from the beam centre their flux densities were scaled according to their positions in the beam.

Correlated flux density from hot spots and nuclear components

The correlated flux density for each observation was determined from the fringe frequency spectrum obtained by transforming all the data for that observation. A comparison of the residual fringe frequency for each significant peak in the spectrum with the expected values for components in the individual lobes and at the location of the optical object enabled unambiguous identification of the observed VLBI components in most sources in which the lobes are separated by $\gtrsim 10$ arc s.

Correlated flux density exceeding a signal-to-noise ratio of 5 was detected in all the sources observed except 3C41 for which only a single 10 m observation was available. The results for sources in which at least one hot spot is likely to have been detected in the outer lobes are presented in Table 4a. The observed components have been identified in Table 4 by the letters A, B or N which refer respectively to the western lobe, the eastern lobe and the nuclear component associated with the optical object. Other relevant information listed in Table 4 is the optical identification, the redshift, the angular separation between the outer lobes, θ_{AB} (taken from ref. 12 and references therein), the measured total flux density at 21 cm and the flux density in the nuclear component at 6 cm as measured by the Cambridge 5 km telescope. A blank in column 6 implies that a nuclear component was not detected at 6 cm and a question mark implies that flux density in the nuclear component cannot be determined unambiguously. The number of different hour angles at which the VLBI observations were made is given in column 7 and the maximum correlated flux density for each component is listed in column 8. A more detailed table giving the measurements at each observed U, V point will be published elsewhere. The errors quoted in column 8 are a quadratic combination of 4% of the total flux density and the r.m.s. noise for that observation.

Table 3 The calibrators

Source	No. of scans	Measured total flux density (21 cm)* (Jy)	Unresolved flux density (Jy)
NRAO 140	2	3.66	3.66
4C39.25	2	2.53	2.05
OQ208	5	0.81	0.81
3C345	2	7.39	6.77
3C454.3	1	10.86	10.23

*For an assumed sensitivity of 1.51 ± 0.06 K Jy^{-1}. This value was derived from the measured antenna temperatures at Effelsberg for all the 3CR sources in the sample and using the total flux densities in Bridle et al.[26].

Sources for which the observed VLBI components are likely to be associated with nuclear components are listed in Table 4b. As can be seen from Table 4a and b the correlated flux density measured by us in the nuclear components at 21 cm is in general less than or only slightly more than that measured at 5 GHz with the Cambridge 5-km telescope. This agrees with the generally accepted result that most nuclear components have flat or inverted radio spectra at these frequencies. We also find that the variation in correlated flux density with hour angle for the nuclear components is in general small, implying that these components are unresolved with the present baseline.

In a few sources, mainly those for which the overall radio structure is not well determined, it is not possible to make unambiguous identifications of the observed VLBI components with known features in their brightness distributions. In the case of 3C43 and 3C454 the correlated flux density shows little variation with hour angle and corresponds to ~26% and ~16% of the total flux at 21 cm, respectively. The overall sizes of the sources are <1 arc s and the total spectra are straight between 38 MHz and 5 GHz with no sign of a flattening at high frequencies[13]. The observed VLBI components in these sources are therefore unlikely to be associated with flat spectrum nuclear components.

In the case of 3C186 only the northern component (A) of the 100 arc s double[14] was observed. This component lies close to the QSO and could itself be double with a component separation of 1.8 arc s (ref. 15). It is uncertain whether the weaker southern lobe is physically related to the QSO. The maximum observed correlated flux density is ~22% of the total at 21 cm and is unlikely to arise in a flat spectrum nuclear component as there is no observed flattening of the total spectrum at high frequencies[13].

The overall size of 3C216 is <1 arc s and the total spectrum which seems to flatten out at frequencies above 1.4 GHz (ref. 13) is consistent with all the correlated flux arising in a flat spectrum nuclear component.

3C245 ($\theta_{AB} = 5''$) has a D2 type structure[16]; the component B being coincident with the QSO[12]. The correlated flux density corresponds to ~47% of the total and could be associated with component B.

A map of 3C380 at 15 GHz (ref. 17) shows this source to be a double with a component separation of ~1.2 arc s, the stronger component possibly coinciding with the QSO. The VLBI component seems to be partly resolved and could be associated with the nuclear component.

Comparison with Cygnus A

It is interesting to compare the properties of hot spots in sources of large redshift with those in the well observed source Cygnus A, which is a relatively close radio galaxy ($z = 0.056$) with an intrinsic luminosity similar to that of the QSOs observed here. Aperture synthesis observations at 5 GHz indicate[18] the presence of four hot spots in Cygnus A with angular sizes between ~1 and 2 arc s. From the available spectral information it is estimated that at 1.4 GHz the hot spots together should account for about 19% of the source flux density, most of which is contributed by two most prominent hot spots numbered A (~7%) in the Np lobe and D(~10%) in the Sf lobe[18]. These spots have physical sizes between about 2 and 3 kpc. Higher resolution observations at 15 GHz (ref. 19) indicate little significant structure on a more compact scale.

From the present VLBI observations it is not possible to estimate the exact shapes of the hot spots or the fractional source flux density which they contain. As the length of the projected baseline does not change significantly over the hour angle range of these observations, the interferometer is sensitive to similar angular scales in most sources. At the mean projected baseline of $1.2 \times 10^6\,\lambda$ the normalised fringe visibilities of gaussian structures with half-intensity diameters of 0.05, 0.1 and 0.15 arc s would be about 0.74, 0.30 and 0.07, respectively. The

maximum correlated fluxes listed in Table 4 are therefore in most cases likely to be lower limits to the flux densities contained in hot spots while the angular diameters of the hot spots are likely to be ≤ 0.15 arc s, which corresponds to ≤ 1.3 kpc at $z = 1$ (for $H = 50\ \mathrm{km\ s^{-1}\ Mpc^{-1}}$ and the Einstein–de Sitter world model), typical of the sources observed.

It is clear from a histogram of the normalised maximum visibility (γ_{max}) for all the sources observed here (Fig. 1*a*) that in over one-third of them the hot spots are responsible for at least 5% of the source flux density, and in this respect are not very different from those in Cygnus A. The physical sizes of these hot spots are, however, likely to be smaller than those of Cygnus A. Hot spots of size >2 kpc at $z > 0.5$ would, in fact, have been completely resolved out in the present experiment. It is therefore possible that hot spots similar to those in Cygnus A are even more common in high redshift sources than is apparent from the present number of detections.

In view of the limited U, V coverage of the observations it is important to ask if the observed visibilities could arise from highly non-gaussian brightness distributions such as uniform disks or linear structures with sizes >0.15 arc s. A circular disk in our case would have a secondary maximum in the visibility curve for a diameter of 0.3 arc s with $\gamma \sim 0.13$. As seven sources have $\gamma_{max} > 0.13$, such distributions are unlikely to be true in general. Higher visibilities at the secondary maximum are possible for linear brightness distributions but the values of γ would be strongly dependent on the hour angle of observation due to projection effects. Only in three of the 13 sources with $\gamma_{max} > 0.05$ was the ratio of γ_{max} to γ_{min} found to be >2 and only in one case >3. As the sources were observed typically at three different position angles differing by over 90° on the sky, such highly elongated components seem to be unlikely unless their maximum dimensions are appreciably smaller than the fringe separation of the interferometer.

The minimum equipartition energy requirements in the hot spots of Cygnus A have been estimated[18] to be of the order of 3×10^{57} erg. It was also shown by Hargrave and Ryle[18] that for inferred equipartition magnetic field of $\sim 3 \times 10^{-4}$ G the radiation lifetime of 5 GHz electrons is only $\sim 5 \times 10^{4}$ yr and that continuing acceleration of electrons must therefore take place in the hots spots and the particles must diffuse out of them rather quickly. These arguments are also valid for the hot spots seen in more distant sources. As the total luminosities of many of the hot spots reported here are comparable with those in Cygnus A, the magnetic field should scale as $V^{-2/7}$, whereas the minimum total energy and the electron lifetimes should scale as $V^{3/7}$, where V is the volume of the hot spots. Because the volumes of the hot spots reported here could be more than 10 times smaller than Cygnus A the electron lifetimes at radio frequencies would be even smaller than in the case of Cygnus A.

Cosmological implications

There is considerable evidence from the observed angular size–redshift relationship for QSOs (see ref. 20) and the angular size–flux density relationship[21,22] that the lobe separations of double radio sources were smaller at earlier epochs. It is important to know if such evolutionary effects may also be present in the sizes of individual lobes of radio sources and of hot

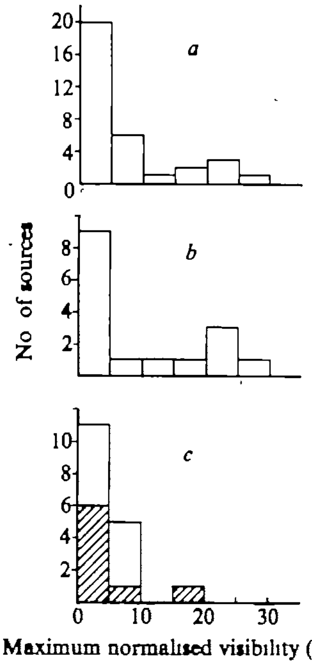

Fig. 1 The distribution of maximum observed correlated flux densities from hot spots, normalised with respect to the total source flux densities, in: *a*, all the sources; *b*, sources with $z > 1$ and *c*, sources with $z < 1$. Sources in which hot spots were not detected have been included in the first bins (0 to 5%). 3C216 and 3C380 have not been included in the histograms and galaxies are shown hatched.

spots within them. A plot of individual lobe sizes with redshift for the 3CR sources shows[8] that at high redshifts ($z > 0.5$) most sources have lobe sizes of only 1–2 arc s which is considerably smaller than expected in reasonable world models if the lobes had similar physical sizes to those at lower redshifts. Our detection of compact hot spots similar in intensity to those in Cygnus A in many high redshift sources implies that the component sizes measured by the Cambridge 5 km telescope for these sources refer to the lobes and not to the hot spots within them. It is therefore likely that the physical sizes of individual lobes of double radio sources undergo similar evolutionary effects with epoch as the lobe separations.

The detection of hot spots of size $\lesssim 0.15$ arc s in high-luminosity sources also suggests that the strong correlation between the fractional flux in hot spots and total source luminosity suggested by Jenkins and McEllin[5] for the 3CR sources with Class II[23] radio structure, suffers from insufficient resolution of the synthesis observations. For this correlation Jenkins and McEllin defined hot spots as regions with a size <15 kpc, which corresponds to an angular size <2 arc s for redshifts $\gtrsim 0.5$. As most radio sources at $z < 0.3$ have measured lobe sizes > 15 kpc and those at $z > 0.5$ have lobes <15 kpc (see ref. 8) the 2 arc s resolution of the synthesis observations is insufficient to distinguish the contribution of hot spots from that of the more extended lobes at higher redshifts (or higher luminosities). But due to the criterion used to define hot spots nearly all the source flux density is considered to arise in hot spots. This could be responsible for much of the observed correlation. Because of the very different angular resolutions it is difficult to compare the fractional flux in hotspots derived from synthesis observations of nearby sources with that detected by VLBI in the present high redshift sample. However, it is interesting that the fractional flux in hotspots at 5 GHz for the 10 sources in the table of Jenkins and McEllin[5] with $z < 0.1$ varies between 5 and 38%, with an average value of 14%, not significantly different from the VLBI visibilities seen in the high redshift sources.

Table 5 Comparison of VLBI and IPS results

	VLBI		IPS	
Source	$\gamma_{\max}$	$\gamma_{\min}$	R	ψ (arc s)
3C43	0.28	0.24	0.51	0.26
3C181	0.22	0.10	0.39	0.47
3C186	0.22	0.09	0.51	0.32
3C196	0.04	0.01	0.33	0.70
3C254	0.06	0.05	0.33	0.64
3C268.4	0.24	0.14	0.51	0.50
3C270.1	0.11	0.05	0.24	0.14
3C280.1	0.02	<0.02	0.45	0.70

If the physical sizes of hot spots in Cygnus A are typical of low redshift sources, as is indicated by IPS observations[6], then the present detection of hot spots with sizes <1 kpc in several of the high redshift sources suggests that the hot spot sizes may also have been smaller at earlier epochs. Some further support for such a possibility may be seen within the present source sample if the sources are divided into two groups depending on whether these have redshifts greater than or less than 1, as shown in Fig. 1*b*, *c*. Although the sample is small the values of $\gamma_{\max}$ seem to be higher in the $z > 1$ sample, as might be expected if the hot spots were more compact at higher redshifts. The observations are, however, also consistent with a weak correlation between the fractional flux in hot spots and redshift.

The possible evolutionary effect indicated by the present observations is contrary to the conclusions of Hewish *et al.*[7] based on IPS observations. Their plot of the inferred angular diameter of hot spots for a sample of 23 strongly scintillating 3CR sources against redshift indicated a strong deficit of sources with diameters <0.3 arc s at redshifts >0.7. This was interpreted by them to imply either that $0.5 < q_0 < 2.0$, or if q_0 is to be smaller, the linear size of hot spots must increase with redshift. But the present VLBI measurements make it doubtful if the angular diameters derived from IPS for high redshift sources refer to true hot spots. This may be seen from a comparison of the VLBI and IPS observations for the eight sources that seem to be common to the two samples at $z > 0.7$ (the IPS data are from ref. 6). Table 6 shows the parameters R and ψ (which are measures of the fractional flux density and the angular diameter of the scintillating component respectively) derived from IPS, together with the values of $\gamma_{\max}$ and $\gamma_{\min}$ in hot spots observed by VLBI.

Based on a new determination of the spectrum of electron density fluctuations in the solar wind, Readhead *et al.*[27] have recently pointed out that the published values of R and ψ should be reduced by ~40% and ~25%, respectively. The revised values have been used in Table 5. The values of ψ quoted in Table 5 have been further reduced by ~20% to convert the e^{-1} full widths used to define the size in ref. 6 to full widths at halfpower. In six of the eight sources, hot spots with angular diameters $\lesssim 0.15$ arc s contain at least 6–28% of the source flux density. The diameters derived from IPS for these sources, on the other hand, are generally >0.3 arc s. The angular diameters of the individual lobes as determined directly from synthesis observations with the Cambridge 5-km telescope are in most cases less than or of the order of 2 arc s. As all structures smaller than about 2 arc s contribute to IPS at 81.5 MHz, the diameters inferred from IPS are likely to be suitably weighted means of the hot spot and lobe sizes. The importance of such a blending of source components in interpreting the IPS results was pointed out earlier by Swarup and Bhandari[24], but it was noted by Hewish and Readhead[25] that the estimated values of R for sources of large z are considerably higher than would be expected if blending were important. The downwards revision by 40% in the values of R, however, makes them consistent with the blending hypothesis.

The present VLBI observations together with the overall source structures determined by aperture synthesis thus suggest that the individual lobes of double sources and perhaps also the hot spots within them were more compact at earlier epochs. Because of the tight correlation between redshift and luminosity in the 3CR sample it is not, however, possible to rule out the dependence of component sizes on absolute luminosity rather than on cosmological epoch. Observations of much weaker samples to see lower luminosity sources at high redshifts are needed to decide between the two possibilities. High-resolution mapping of compact structures in the radio lobes may also throw light on the physical nature of the evolutionary mechanism.

We thank A. van Ardenne for his work on the Westerbork array and for assistance with the observations, also J. D. Bregman, H. W. van Someren Gréve, J. E. Noordam, J. G. Robertson, R. Porcas, I. I. K. Pauliny-Toth, B. J. Geldzahler and K. W. Weiler for help and advice. The Rb standard at Westerbork was lent by the van Swinden Laboratory in Delft for which we thank R. Kaarls and G. de Jong. The Westerbork telescope is operated by the Netherlands Foundation for Radio Astronomy with the financial support of the Netherlands Organization for the Advancement of Pure Research (Z.W.O.).

Isotopes of tellurium, xenon and krypton in Allende meteorite retain record of nucleosynthesis

R. V. Ballad, L. L. Oliver, R. G. Downing & O. K. Manuel

Department of Chemistry, University of Missouri, Rolla, Missouri 65401

Various mixtures of r-, p- and s-nucleosynthesis products have been observed in the isotopes of tellurium, xenon and krypton extracted from mineral separates of the Allende meteorite. The presence of several isotopically distinct components in these high Z elements and the close association of isotopically normal low Z elements with particular isotopes of the high Z elements suggest that our Solar System may have formed directly from the debris of a single precursor star, approximately concentric with the present Sun.

THE enrichment of heavy xenon isotopes in carbonaceous chondrites is always accompanied by an enrichment of the light, fission-shielded isotopes. It has been suggested that this anomalous xenon might represent a mixture of r- and p-products added to the Solar System from a nearby supernova[1]—previously the excess heavy isotopes were widely regarded as fission products, designated CCF as an acronym for carbonaceous chondrite fission[2]. More recent reports of nucleogenetic anomalies in the isotopic compositions of several other elements in meteorites[3–10] and identification[11] of the decay product of extinct ^{26}Al have resulted in three different models of element synthesis shortly before condensation: (1) The anomalous elements and short-lived isotopes might have been generated in remote nucleosynthesis events, such as supernovae[12,13] or red giant stars[14,15], and then trapped in grains which were subsequently incorporated into the early solar nebula. In such a case the short-lived isotopes themselves would not necessarily survive until the grains entered the solar nebula, but the more refractory dust grains might survive conditions in the nebula and be incorporated into meteorites with alien nucleosynthesis products and the decay products of short-lived isotopes. (2) The anomalous elements and short-lived isotopes might have been generated in a nearby supernova[16]. If the shock wave from this supernova caused collapse of the presolar nebula, then the nucleosynthesis event is directly related to the birth of the Solar System and occurred about 4.6×10^9 yr ago. (3) The Solar System might have formed directly from the debris of a single supernova[17–19]. In this case the anomalous elements and short-lived isotopes were made by the same nucleosynthesis events which produced other elements in the Solar System, and the present Solar System retains the chemical characteristics of the supernova: The Sun accumulated on the supernova core, iron meteorites and cores of the terrestrial planets were formed primarily from elements synthesised in the hot stellar interior, and the outer planets and the carbon phase of chondrites were condensed from elements of the cooler outer layers, the only region which contained low-Z elements.

Two recent reviews[20,21] suggest that model (2), a nearby supernova, has gained favour as a reasonable working hypothesis. However, the results of analyses on noble gases trapped in the metal phase of iron meteorites[22] and in gas-rich xenoliths[23] from the Earth's mantle have been interpreted as supporting model (3). Other tests were suggested for model (3), including its prediction that the acid-resistant carbon which contains anomalous xenon should also contain isotopically anomalous components of other high-Z elements[22]. Subsequently, Arden[6] has reported large isotopic anomalies of uranium in acid-resistant minerals of several chondrites, but it was uncertain whether these were generated by stellar nuclear reactions or by chemical fractionation of the precursor elements of ^{235}U and ^{238}U. The present study was therefore undertaken to test the prediction of model (3) at tellurium ($Z=52$), an element with an atomic number near that of xenon ($Z=54$) and with eight natural isotopes that are only inefficiently produced by fission.

Srinivasan followed procedures developed elsewhere[24–27] to isolate the following acid-resistant fractions from a crushed sample of bulk Allende weighing 11.66 g. (*a*) Residue A: Etch-

ing bulk Allende in HCl and HF acids for a 6-week period produced residues weighing 0.53% of the bulk sample. Previous studies[24–27] on Allende residues suggest that carbon, chromite, spinel and an ill-defined mineral Q are the main constituents of residue A. (*b*) Residue B: Etching residue A in concentrated HNO_3 dissolved Q (refs 26, 27), leaving a residue weighing 0.42% of the bulk Allende sample. (*c*) Residue C: Refluxing residue B in a mixture of concentrated acids, H_3PO_4 and H_2SO_4, for 2 h dissolved[28] the chromite and spinel (and perhaps part of the carbon) to produce residue C, weighing 0.19% of the bulk sample. (*d*) Dissolution of C: Refluxing residue C for 1 h in a mixture of concentrated acids, H_3PO_4 and H_2SO_4, plus CrO_3, dissolved residue C.

Nucleosynthetic products in xenon and krypton

A high sensitivity noble gas mass spectrometer was used to determine the isotopic compositions of xenon and krypton released by stepwise heating of a 3.1-mg aliquot of residue B, labelled B-1, and a 1.7-mg aliquot of residue C, labelled C-2. Procedures for extraction and analysis of noble gases were as described previously[22]. The isotopic compositions of xenon and krypton in these residues are presented in Tables 1 and 2, respectively. The xenon in both residues displays the now familiar pattern of enrichment in the light and heavy isotopes.

The part (chromite, spinel and perhaps some carbon) of residue B which dissolved (54% by weight) in producing residue C is referred to collectively as spinels in Tables 1 and 2. The concentrations and isotopic structures of gases in these spinels were calculated from differences in the isotopic compositions and total gas contents of residues B and C. Superficially the isotopic composition of xenon and krypton in Allende spinels is similar to that reported recently in the high temperature fractions of Murchison residues which were etched in alkaline oxidants to remove organic polymers[15]. It was reported that X-ray diffraction of the severely etched Murchison residues showed mainly chromite and minor spinels—minerals which probably constitute the bulk of our Allende spinels. As was observed in the high temperature fractions of these Murchison residues[15], the xenon in Allende spinels is enriched in ^{130}Xe and depleted in ^{136}Xe, and the krypton in these spinels seems to be enriched in ^{82}Kr and depleted in ^{83}Kr. However, the isotopic composition of Kr in our spinels cannot be distinguished from bulk krypton in carbonaceous chondrites or in air, within the limits of experimental error. A detailed examination of the xenon spectrum in Allende's spinels is instructive in evaluating the model proposed to explain the high temperature xenon in Murchison's spinel—s products trapped in presolar dust grains that were ejected from red giant stars[14,15].

The isotopic spectra of xenon in Allende's carbon and spinels are shown in Fig. 1, normalised to xenon in average carbonaceous chondrites (AVCC) in the following manner.

$$g^{i}_{132} = ({}^{i}Xe/{}^{132}Xe)_{sample}/({}^{i}Xe/{}^{132}Xe)_{AVCC} \qquad (1)$$

Since the *in situ* decay product of ^{129}I may comprise part of the

* See Table 1 footnote for method used to calculate amount of each isotope in spinels

^{129}Xe abundance, this isotope is not used to define the general anomaly pattern of isotopes trapped in Allende's spinels and carbon. Abundances of the other xenon isotopes in carbon and spinels display opposite anomaly patterns. We suggest that these mineral fractions trapped different components of AVCC xenon, that is, carbon is enriched in r and p products and spinels are enriched in s products of the nucleosynthesis reactions which collectively produced the isotopes of bulk xenon in carbonaceous chondrites. It seems highly unlikely that the carbon and spinel fractions are both interstellar grains, or that either the carbon or the spinels forming in the primitive nebula were selectively exposed to alien xenon from nearby supernovae or red giant stars. There are other indications that noble gases in Allende do not represent alien nucleosynthesis products. Allende's carbon contains helium and neon with normal planetary isotopic compositions[29], and the carbon itself has a normal value of ^{12}C/^{13}C (ref. 30). The ^{82}Kr/^{130}Xe ratio in Allende's spinels is 2.6, which is close to the value of ^{82}Kr/^{130}Xe = 1.8 in bulk Allende[26] and about a factor of 10 higher than the value that Srinivasan and Anders[15] report for this ratio in the gas component from red giant stars.

Variations in the abundance of the lightest and heaviest xenon isotopes in gas released by stepwise heating of Allende's acid-etched residues are shown graphically in Fig. 2. Xenon isotopes released from the carbon (C-2) and spinel/carbon (B-1) fractions define different correlation lines. These do not agree with the correlation shown by Lewis *et al.*[26,27] for other etched residues of Allende (dashed line in Fig. 2), nor do they pass through the composition of AVCC or 'trapped' (ref. 26) xenon. Since ^{132}Xe may be produced by both r- and s-processes[31], it is preferable to normalise the xenon spectra to a pure s-product, ^{130}Xe.

As shown in Fig. 3*A*, this method of normalisation permits us to compare trends in isotopic ratios with trends expected from the addition of pure s-, r- and p-nucleosynthesis products to AVCC xenon. It can be seen in Fig. 3*B* that xenon isotopic ratios from stepwise heating of our two Allende residues do not follow the trend reported earlier[26,27] (dashed line in Fig. 3*A*), but it can be seen in Fig. 3*C* that ratios for the total xenon in these residues seem to do so. Isotopic ratios of the total xenon in other etched residues of Allende[26,27] also lie along the dashed line shown in Fig. 3*A*, as expected by mixing only two components. But isotopic ratios of xenon released by stepwise heating of individual residues from Allende and Murchison, as shown in Fig. 3*D*, *E* and *F*, cannot be explained by a simple binary mixture. Kuroda[32] also notes that a simple binary mixture fails to explain isotopic ratios of xenon released by stepwise heating of bulk carbonaceous chondrites. Although the spectra in Fig. 3 confirm the positive correlation between enrichments of light and heavy xenon isotopes[1], and the spectra in Fig. 1 suggest that bulk AVCC xenon may be represented as a mixture of one s-enriched component with one s-depleted component, differences in the slopes of the correlation lines in Fig. 3 indicate that the r and p products of chondritic xenon were not completely mixed before trapping. Since the r and p processes occur in the supernova explosion[31], to explain these xenon spectra as a consequence of injections from a nearby supernova[1,16] would require the preservation of heterogeneities within the supernova material itself as the alien xenon was transferred into the solar nebula and then trapped on a matrix of isotopically normal carbon.

Variations in the isotopic composition of krypton (Table 2) provide additional evidence for nucleogenetic effects in the residues of Allende. Since the anomalies in krypton are relatively small and others[15,33] have recently discussed the evidence for s- and r-products in krypton extracted from acid-etched minerals of carbonaceous chondrites, a detailed discussion on the krypton anomalies shown in Table 2 is not warranted.

Nucleosynthetic products in tellurium

If Allende's carbon itself formed in the outer layers of a supernova, then other heavy elements trapped in the carbon would be expected to show enrichments of r- and p-products similar to those observed in xenon. To test this, the abundance of six stable isotopes, ^{i}Te, i = 120, 122, 124, 126, 128 and 130, was determined in Allende's residues by neutron activation and γ-ray spectrometry on the (n, γ) product ${}^{i+1}$Te. For these analyses a 32-mg aliquot of residue B, labelled B-3, was irradiated for 95 h at a flux of 6×10^{14} neutrons cm^{-2} s^{-1}. Monitors of tellurium, uranium, osmium and ruthenium were irradiated with the sample. Carriers of tellurium, iodine (to carry fissiogenic ^{133}I), osmium and ruthenium were added to the irradiated sample during etching to isolate the activation products from fractions of the residues rich in spinels and carbon, respectively. Standard radiochemical procedures were used to recover tellurium[34–38] and iodine[39], and to recover and separate osmium and ruthenium[35,40–45]. The only special reagent, potassium chlormilexathiocyanate, was prepared as described by Morgan[45] and

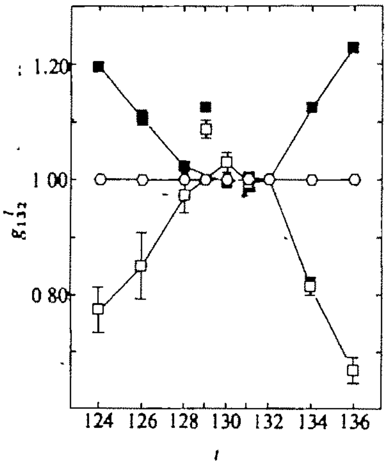

Fig. 1 Isotopic compositions of xenon in Allende's spinels (□) and carbon (■) normalised to AVCC xenon (⬡) in the manner given by equation (1). Since ^{129}Xe may contain the *in situ* decay product of ^{129}I, it is not used to define the isotopic abundance pattern of trapped xenon. Carbon is enriched in r and p products of xenon, spinels are depleted in these, and bulk AVCC xenon has an intermediate abundance pattern for the eight nonradiogenic isotopes of xenon.

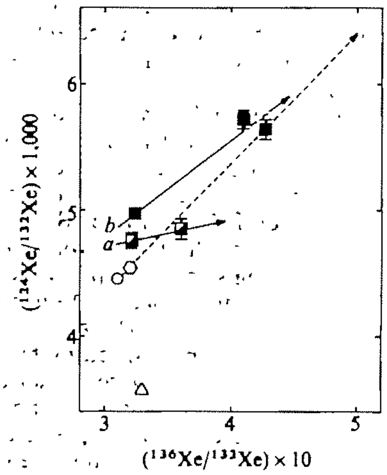

Fig. 2 Variations in abundances of the lightest and heaviest isotopes of xenon released by stepwise heating of Allende's residues. Xenon isotopes released from the mixed residue of carbon and spinels (◪) lie along line *a*, xenon isotopes from the carbon residue (■) lie along line *b*, and xenon isotopes in other residues of Allende are reported[26,27] to lie along the dashed line connecting 'fission-free' or 'trapped' xenon (○) and 'strange' xenon generated by fission and mass fractionation. ⬡, AVCC; △, air.

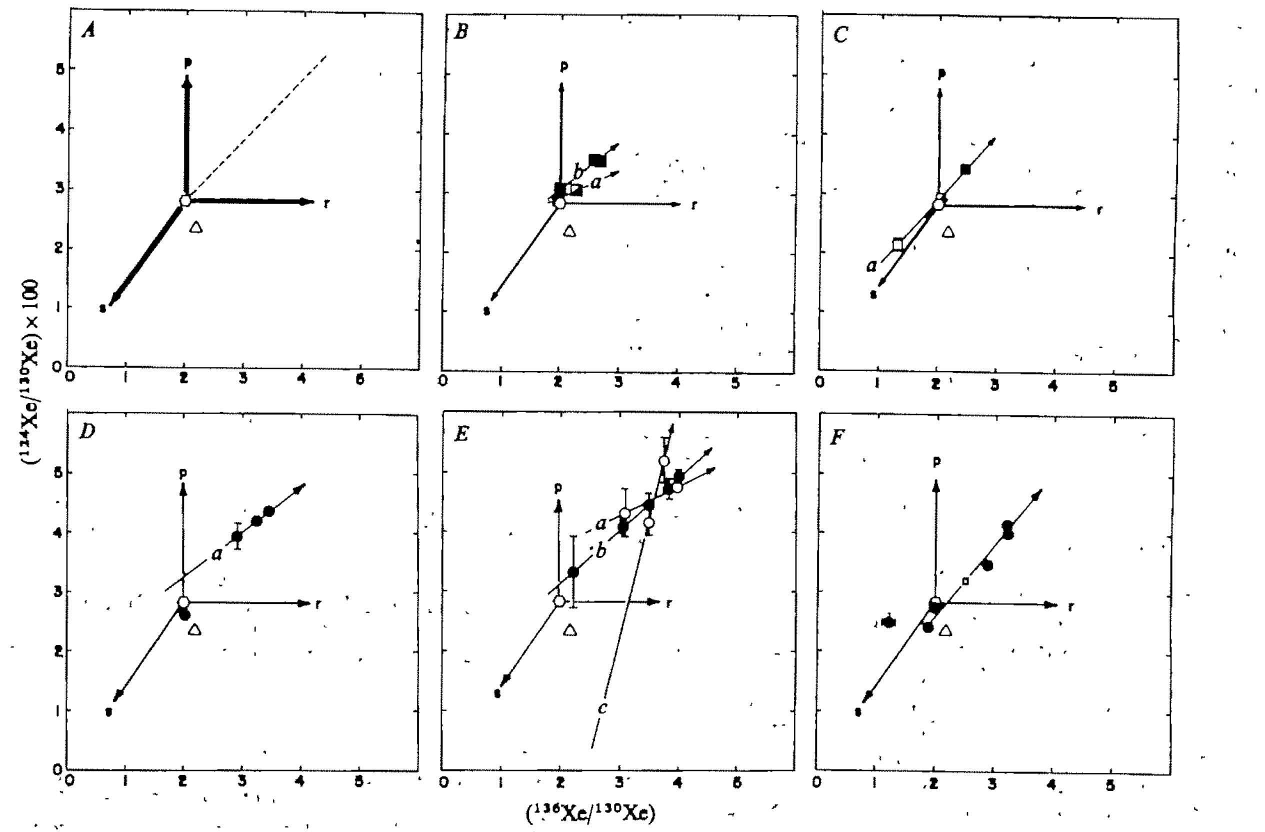

Fig. 3 Ratios among three xenon isotopes produced by the r, p and s processes of nucleosynthesis. *A*, A comparison of trends expected by the addition to AVCC xenon of pure nucleogenetic components from the r, p and s processes (dark arrows) with trends reported from earlier analyses[26,27] on Allende residues (dashed line); *B*, trends observed in this study for xenon released by stepwise heating of Allende's carbon (C-2) (line *b*) and carbon plus spinels (B-1) (line *a*); *C*, trends observed in this study for total xenon in Allende residues: *a* is B-1, C-2 mixing line; *D*, the trend observed in an earlier study[26] on xenon released by stepwise heating of one Allende residue (●), *a* is 3CS2; *E* trends observed in another study[27] on xenon released by stepwise heating of three Allende residues (○, ●) 4C57 (*a*), 4C56 (*b*) and 3CS59 (*c*); *F*, trends observed[15] in xenon released by stepwise heating of a Murchison residue (●) (*a*, ICIO). Other symbols are defined in Figs 1 and 2. All error limits greater than the size of the symbols are shown, except for the two temperature fractions of Murchison (Fig. 3*F*) with low values of ^{124}Xe/^{130}Xe. Error limits were not reported[15] on the latter. △, Air; ⬡, AVCC.

used in the precipitation of osmium and ruthenium. Attempts to measure the isotopic compositions of osmium and ruthenium were abandoned after our results showed that these elements are highly enriched on the residues, apparently as a result of their insolubility in the etching acids[46], and display no large isotopic anomalies.

A Ge(Li) detector and a thin-crystal, intrinsic Ge detector were used with a 1,024-channel analyser to determine the activity of each tellurium isotope relative to the activity of ^{129}Te in the samples and in the monitors. The latter were prepared from purified TeO_2 (lot 766061, Fisher Scientific). Possible interferences which might produce $^{i+1}$Te from neutron-induced reactions on other elements in the samples are (1) neutron-induced fission of uranium to produce ^{131}Te and ^{129}Te, (2) the (n, p) reaction on iodine and the (n, α) reactions on xenon, and (3) the (n, γ) reaction on ^{124}Sn followed by two successive β decays. Our results indicate a ^{128}Te concentration of 16 p.p.m. in the carbon and 21 p.p.m. in spinels, corresponding to total tellurium content of 51 and 67 p.p.m., respectively, if all other isotopes were present in the proportion observed for terrestrial tellurium. The activity of fission-produced ^{133}I and ^{132}Te in each residue and in the uranium monitor indicate that interference from neutron-induced fission of uranium produces 1.1% of the ^{131}Te activity and 0.5% of the ^{129}Te activity in the irradiated carbon, and fission interference produces 0.9% of the ^{131}Te and 0.4% of ^{129}Te activities in the irradiated spinels. The results of our tellurium and xenon analyses (Table 1) yield atomic ratios of Te/Xe ≈ 5×10^4 in carbon and Te/Xe ≈ 1.5×10^5 in spinels. From the amounts of radiogenic ^{129}Xe in these residues (Table 1) and an assumed value of $^{129}I/^{127}I = 10^{-4}$ for trapped iodine[47], we calculate atomic ratios of Te/I ≈ 130 in carbon and Te/I ≈ 480 in the spinels. The ^{127}I (n, p) reaction and the $^{124-134}$Xe (n, α) reactions have Q values of about 0.1 MeV and 2.5–6.3 MeV, and they are inhibited by Coulomb barriers of about 8 MeV and 14 MeV, respectively. Thus, each of the interference reactions listed under item (2) requires neutron energies above 8 MeV. All of the relevant cross-sections for (n, p) and (n, α) reactions are not known, but typically these are only a few millibarns for 14 MeV neutrons on target elements with $Z \approx 50$–60 (ref. 48). In the position where our samples were irradiated, the flux of neutrons above 8 MeV is about 1×10^{-3} of the thermal flux. From the atomic ratios given above and assuming cross-sections of 1,000 mb for each (n, p) and (n, α) reaction, we estimate upper limits for interference on any tellurium isotope to be 0.03% from the (n, p) reaction and 1×10^{-4}% from the most favourable (n, α) reaction. Concentrations of tin, the target element for interference from above item (3), were not measured in our Allende residues. In other Allende residues prepared in a similar manner, the highest concentration of germanium, a neighbour of tin in the Group IV A elements, is reported[46] to be 37 p.p.m. If our Residue B (carbon + spinels) contained 37 p.p.m. germanium, we calculate lower limits on the atomic ratios of Te/Sn ≫ 11 in carbon and Te/Sn ≫ 18 in the spinels, assuming a solar value for the Sn/Ge ratio[49] and assuming that the mineral fraction being considered, carbon or spinels, each contain all of the germanium of Residue B. The ^{125}Sn produced by neutron-capture on natural ^{124}Sn must undergo two β-decays before becoming an interference at ^{125}Te. An intermediate decay product, ^{125}Sb ($t_{1/2} = 2.73$ yr), acts to shield ^{125}Te from most of the ^{125}Sn decays, and we calculate an upper limit of 0.1% for the interference at ^{125}Te from the ^{125}Sn (n, γ, β, β) reaction. Interference from he (n, 2n) reaction on ${}^{i+2}$Te is expected to be negligible; for these reactions, $Q \gg 8$ MeV.

The results of counting data accumulated from 5 February 1978 to 28 May 1978 are shown in Table 3, corrected for the fission interference discussed above. It should be stressed that we measured only relative abundances of tellurium isotopes in the monitors and in the samples. The maximum variation that Smithers and Krouse[50] observed in isotope ratios in six natural tellurides and two commercial tellurium salts corresponds to a fractionation of only 0.05% per mass unit, variations which could not be detected by the techniques used in this study. We therefore assume that the tellurium in our monitors has normal values for isotope ratios, and that the activity of each isotope, ${}^{i+1}$Te, is iroportional to the abundance of the stable (n, γ) target isotope, ^{i}Te. Thus, the activities shown in Table 3 can be expressed in an analogous manner to that given for xenon isotopes in equation (1).

$$g'_{128} = ({}^{i}\mathrm{Te}/{}^{128}\mathrm{Te})_{\mathrm{sample}}/({}^{i}\mathrm{Te}/{}^{128}\mathrm{Te})_{\mathrm{standard}} \qquad (2)$$

The results of our analyses on tellurium isotopes in Allende residues are shown graphically in Fig. 4. As ^{126}Te may contain a radiogenic decay product from *in situ* decay of a precursor isotope produced in the r-process, ^{126}Sn ($t_{1/2} \sim 10^5$ yr) (ref. 51), the abundance of ^{126}Te is not used to define the general anomaly pattern of tellurium isotopes trapped in these residues. No data are available on the isotopic composition of tellurium in average carbonaceous chondrites, AVCC tellurium. Therefore, the patterns of isotopic anomalies shown in Fig. 4*A* (carbon) and Fig. 4*B* (spinels), where the isotopic ratios are normalised to the terrestrial tellurium standard, are not analogous to the patterns shown in Fig. 1 for xenon in these same residues. The xenon spectra in Fig. 1 are normalised to an AVCC xenon standard.

In spite of differences in reference standards used in Figs 1 and 4, the following observations may be significant: (1) The nonradiogenic isotopes of tellurium and xenon in Allende's carbon, as shown in Fig. 1 and Fig. 4*A*, produce remarkably similar anomaly patterns. Both elements are enriched in the heaviest isotopes, ^{130}Te and ^{136}Xe, and in the lightest isotopes, ^{120}Te and ^{124}Xe. These isotopes are produced on a very short time scale by the r and p processes in supernova explosions[31,32]. (2) The spinel-rich fraction of these minerals (Figs 1 and 4*B*) is enriched in the intermediate mass isotopes of each element, ^{130}Xe and ^{124}Te. These isotopes are generated over long periods of stellar evolution by the s process[14,31]. (3) The existence of isotopically anomalous tellurium in Allende cannot be explained by a single AVCC-type tellurium, since the isotopic spectrum of tellurium in carbon is obviously different from that in the spinels. (4) The spinel-rich fraction of Allende residues is enriched in ^{130}Te (Fig. 4*B*) but not in ^{136}Xe (Fig. 1). This apparent discrepancy between the abundances of r products in tellurium and xenon may indicate that etching the Allende residues has separated the r and p products of tellurium, just as stepwise gas extraction separated the r and p products of xenon (Fig. 3). Or this may be due to differences in the reference standards for the xenon and tellurium spectra, that is, it is possible that AVCC tellurium is systematically enriched in ^{130}Te relative to terrestrial tellurium.

Nucleogenetic heterogeneities in element abundances

In using the results of this study to evaluate the merits of models suggested for element synthesis shortly before condensation[17–19], it is imperative to consider the constraints imposed by earlier analyses[26] on noble gases in Allende's residues. These measurements revealed elemental abundances of helium and neon which correlate linearly with abundances of the r products in xenon[17–19], as shown in Fig. 5, and the correlations yield zero values of helium and neon at ^{136}Xe/^{132}Xe = 0.32±0.01. This value of ^{136}Xe/^{132}Xe contains the range of isotopic ratios for planetary xenon in air, carbonaceous chondrites and ureilites. It is now widely accepted that variations of the ^{136}Xe/^{132}Xe ratio in carbonaceous chondrites may be nucleogenetic[1,5,9,12–23,33], and that stellar evolution selectively depletes low-Z elements from the hotter stellar interior[31]. It can be concluded that normal, planetary xenon was synthesised in the hot stellar interior and that the inertness of noble gases made it possible for these elements to preserve a record of both elemental and isotopic heterogeneities which existed before condensation. Most other elements formed compounds which were chemically segregated into different minerals of planetary solids. Small variations in the isotopic compositions of normal planetary xenon, as seen in bulk ureilites[53,54], carbonaceous chondrites[55], and air[56], are identified in Fig. 5 at values of ^{136}Xe/^{132}Xe = 0.313, 0.322 and 0.330, respectively. Correlation coefficients between the elemental and isotopic ratios shown in Fig. 5 are between 99.2% and 99.9%. It has been reported[26] that a plot of ^{124}Xe/^{130}Xe against ^{136}Xe/^{130}Xe for xenon in these same residues rave a correlation coefficient of 98%.

We did not determine helium and neon in our study but have used the trends shown in Fig. 5 in interpreting our results, since the results of other studies on noble gases in residues of Allende[27,33,57] and Murchison[58] confirm these correlations.

Table 3 Ratios of γ-ray intensities detected from activated tellurium isotopes

Isotopes	Carbon-terrestrial	Spinels terrestrial	Carbon spinels	γ-Energies detected (MeV)	Half-life observed
^{121}Te	106.9±2.6	102.3±1.9	105.4±1.4	0.573	20–30 d
^{123}Te	104.3±2.5	100.1±2.4	103.7±2.2	0.159	120 d
^{125}Te	97.6±0.5	102.4±0.6	95.4±0.5	0.035*	58 d
^{127}Te	105.1±4.1	100.4±3.9	103.4±3.6	0.418	110 d
^{129}Te	≡100.0	≡100.0	≡100.0	0.696, 0.027*	34 d
^{131}Te	111.4±4.0	117.5±3.4	94.8±1.7	0.775, 0.850	30 h

* Counted with intrinsic Ge detector

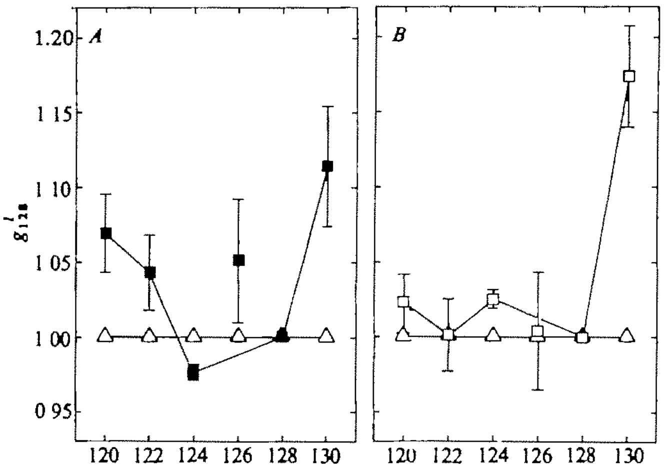

Fig. 4 Isotopic compositions of tellurium in Allende's carbon (■) and spinels (□) normalised to that in the tellurium monitor (△) in the manner indicated by equation (2). Since ^{126}Te may contain the *in situ* decay product of ^{126}Sn, it is not used to define the isotopic abundance pattern of trapped tellurium. *A*, The anomaly pattern of tellurium isotopes in carbon resembles that observed for xenon isotopes (Fig. 1) in carbon; *B*, the anomaly pattern of tellurium isotopes in spinels reveals an enrichment of the s product, ^{124}Te, and the r product, ^{130}Te.

These correlations are also seen in bulk noble gases of meteorites. Most carbonaceous chondrites contain helium and neon, and stepwise heating[1] or chemical etching experiments[26] on carbonaceous chondrites reveal the presence of an anomalous xenon component with ^{136}Xe/^{132}Xe>0.32. However, Marti and Wilkening[59] report that the stepwise release of gases from the Kenna ureilite revealed the presence of a single xenon component with ^{136}Xe/^{132}Xe$=0.312$, but they found no evidence of trapped helium or neon although the ureilite contained large amounts of heavy noble gases.

Conclusions

The presence of isotopically anomalous tellurium in Allende provides additional evidence for the suggestion that isotopically anomalous components in xenon in carbonaceous chondrites are nucleogenetic[1,5,9,12–23,33] rather than fission products[2,26,27,46,58]. The following observations are difficult to explain by alien grains carrying nucleosynthetic products from supernovae[12,13] or red giant stars[14,15]: (1) The carbon grains have a normal value of ^{12}C/^{13}C (ref. 30), (2) the carbon contains anomalous xenon, krypton and tellurium and normal helium and neon[29], (3) isotopic ratios of xenon enriched in s products lie on the correlation line defined by isotopic ratios of xenon enriched in r and p products (Fig. 3*A*, *C*), and (4) there was no helium or neon in the primitive noble gas component which contained normal, planetary xenon (Fig. 5 and ref. 59). Trapping of alien nucleosynthetic elements from a nearby supernova[1,16] onto a matrix of isotopically normal material can explain observations (1) and (2), but not observations (3) and (4). The observation that r and p products from the supernova event are not mixed (Fig. 2, Fig. 3*B*, *D–F*, Fig. 4) also requires that the injected material remain heterogeneous as it was transferred from the supernova to the solar system. Even if this occurred, it seems highly unlikely that the abundance pattern of xenon isotopes from supernovae[1,16] and red giant stars[14,15] would be mirror images and that these two alien forms of xenon would be fortuitously trapped in meteorites in which the bulk xenon isotopes display an intermediate abundance pattern (Fig. 1).

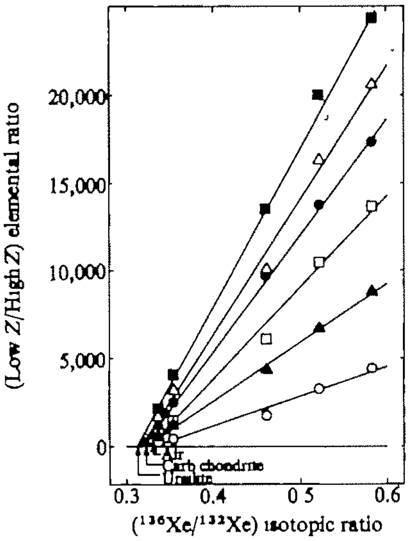

Fig. 5 Correlations between values of the isotopic ratio, ^{136}Xe/^{132}Xe, and elemental ratios of (low-*Z*/high-*Z*) noble gases in residues of Allende[26]. Measured values of elemental ratios are multiplied by constants so that all six ratios can be shown together. Values of (^{20}Ne/^{132}Xe)×60 are depicted by (■), (^{4}He/^{132}Xe)×0.25 by (△), (^{20}Ne/^{36}Ar)×4,000 by (●), (^{20}Ne/^{84}Kr)×25 by (□), (^{4}He/^{36}Ar)×10 by (▲), and (^{4}He/^{84}Kr)×0.04 by (○). The correlations yield zero values for the elemental abundances of helium and neon at a value of ^{136}Xe/^{132}Xe$=0.32\pm0.01$. This corresponds to the ^{136}Xe/^{132}Xe ratio of bulk xenon in air, carbonaceous chondrites, and ureilites, as shown at ^{136}Xe/^{132}Xe$=$ 0.330, 0.322 and 0.313, respectively.

The isotopically anomalous components of tellurium, xenon and krypton observed in this study can be understood as remnants of the different nucleosynthesis processes which collectively produced the chemical elements of the Solar System. The opposite anomaly patterns of xenon (Fig. 1), the incompletely mixed r and p products in xenon (Fig. 2, Fig. 3) and in tellurium (Fig. 4), the association of isotopically anomalous high-*Z* elements with isotopically normal low-*Z* elements, and the absence of helium and neon in the noble gas component with normal, planetary xenon (Fig. 5, ref. 59) are consistent with the suggestion that our Solar System formed directly from the debris of a single supernova[17–19].

We thank Drs B. Srinivasan for sample preparation and assistance with noble gas analysis, David McKown and Phillip Hopke for use of their counters and Elbert King for the sample of Allende. This research was supported by the USNSF, NSF-EAR78-09251.

DNA sequences and structural homologies of the replication origins of lambdoid bacteriophages

R. Grosschedl & G. Hobom
Institut für Biologie III, Universität Freiburg, FRG

*The DNA sequences for the origins of replication of the lambdoid bacteriophages φ80, 434, φ21, and λ*imm*21 (identical to φ21) have been determined and compared to the λ structure. Two presumptive elaborate binding sites for two initiator proteins have been identified in their outer sections, while a replicational primer start site seems to be located in their centres.*

BACTERIOPHAGE λ initiates DNA replication bidirectionally from a unique site on its circularised genome. This site has been located at approximately 80% of the linear DNA molecule measured from the left end[1,2]. A group of *cis*-dominant, replication-defective λ phages (λ *ori*$^-$) has been isolated[3,4], and four such mutations have now been characterised by DNA sequence analysis[5,6]. All are located within the λ *O* gene[7], immediately to the left of an *Eco*RI restriction site at 81% λ (ref. 8). While the segment of λ DNA covered by the *ori*$^-$ mutants (comprising 63 base pairs, ref. 5) gives a lower limit for the λ origin sequence, a 202 base pair upper, functional limit has been observed in hybrid plasmid cloning studies[9].

The lambdoid phages 434, φ21, and φ80 are genetically very similar, and can exchange functionally corresponding though not necessarily identical (or heteroduplexing) segments of their genomes with λ or with each other[10–12]. Heteroduplexing DNA segments can also be observed in electron microscope analysis of pairs of lambdoid phage DNAs[13–15]. In particular, the regions surrounding the origins of replication, although located at somewhat different positions within the various phage DNAs, form heteroduplexes among the subgroup λ, 434 and φ21, whereas the corresponding region of φ80 DNA seems to be different, and heteroduplexes with λ only in a right-hand section of that region. Genetic observations[16] also indicate exchangeability of the analogous gene *O* products among λ, 434 and φ21, while the φ80 *O* function is not exchangeable with any of the others. The φ80 *O* protein is also different in size[17]. The products of the various *P* genes located to the right of the *O* genes can, however, be exchanged among all members of this group (even if only asymmetrically in one case[17]), although functional differences can still be detected[18].

While the origin of replication constitutes at least part of the replicator structure as proposed by the replicon hypothesis[19], the phage coded proteins O and P seem to fulfill the role of specific initiator proteins also predicted by this model. And the specific binding of the phage's own initiator protein(s) to its replicator structure seems to determine at least in part the individuality of these phage replicons, as being distinct from the cellular genome. In addition, besides the requirement for a supercoiled, circular DNA substrate[20], initiation of λ replication has been shown to depend on local transcription at or near the origin of replication (transcriptional activation)[21–24]. When initiated, λ DNA synthesis requires most of the proteins that are essential parts of the *Escherichia coli* replication machinery, including *dna*B, *dna*G, and *dna*E (polymerase III)[18].

Detection (in a colE1–λ hybrid plasmid system) of a second, unconnected replicator element located within the *c*II gene has led us to redefine the λ (lambdoid) origin of replication as a signal structure that constitutes (only) the start site for a replicational primer synthesis, most probably catalysed by *dna*G coded primase[9]. DNA strand separation is a prerequisite for daughter strand DNA (or RNA) synthesis, and by definition the origin of replication in a preceding step must also be the origin of strand separation during initiation; strand separation also seems to be required for the action of primase[25]. We assume, therefore, that facilitation of local DNA strand separation, and hence exposure of a promoter-analogous primase binding site[26,27], will be a basic property of the origin of replication. In addition, it may possibly also be involved in attachment of the DNA replicon to a structurally organised replication site (replisome), and in protection of the nascent replicational primer 5′-end (for discussion see ref. 28).

To look more closely at the lambdoid origin of replication we have sequenced the 434, φ21 and φ80 origin segments and compared them to λ (ref. 6). On the basis of this analysis, the λ (lambdoid) origin of replication can be deduced from structural considerations to consist of 156 base pairs, extending in both directions from its 63 base pair minimum, and included within the 202 base pair maximum size as mentioned above.

Aligning lambdoid origin DNA sequences in parallel

The various origins of replication were sequenced using the dimethylsulphate/hydrazine technique[29] (Figs 1 and 2). The 434 and φ21 sequences are almost identical with λ, but the φ80 DNA sequence differs from the others for most of its length. All four DNA sequences, however, are identical or at least nearly identical (see boxes in Fig. 3) in several stretches within the functional limits of the λ (φ21) origin[9]. The largest of these stretches is 31 base pairs long with only two internal λ/φ80 non-homologies (one is also found in φ21 DNA), and includes the *Eco*RI cleavage site common to all of them. The coding frame for this part of the *O* gene sequence also seems to be the same. With the φ80 DNA sequence clearly diverging from the other lambdoid DNA sequences to the left of position λ:1,099/φ80:1,100 and to the right of position λ:1,169/φ80:1,170, we regard the 31 base pair identical stretch to be a fixed point around which all the origin sequences can be aligned both structurally and functionally.

Against this background, λ/φ80 DNA homologies provide positive evidence for functionally important segments within the origin of replication structure, which can be cross-checked against defective λ *ori*$^-$ mutant[5,6] or other partial deletion[9] sequences. The sequence deviations within the λ/434/φ21 group are considered to point to positions of minor functional importance. Although some of the sequence deviations between φ80 DNA and the other lambdoid phages may similarly point to positions of minor importance, others should indicate specific alterations to serve analogous, but phage-specific functions.

When the DNA sequences of the lambdoid origins of replication are aligned in parallel they display a surprisingly complex, but analogous order of symmetry elements. Taking other characteristic features into account, three distinct regions with very little overlap (Fig. 3) can be identified. Besides these three sections there are two short external tail segments, which differ

0028–0836/79/0277—0621$01.00

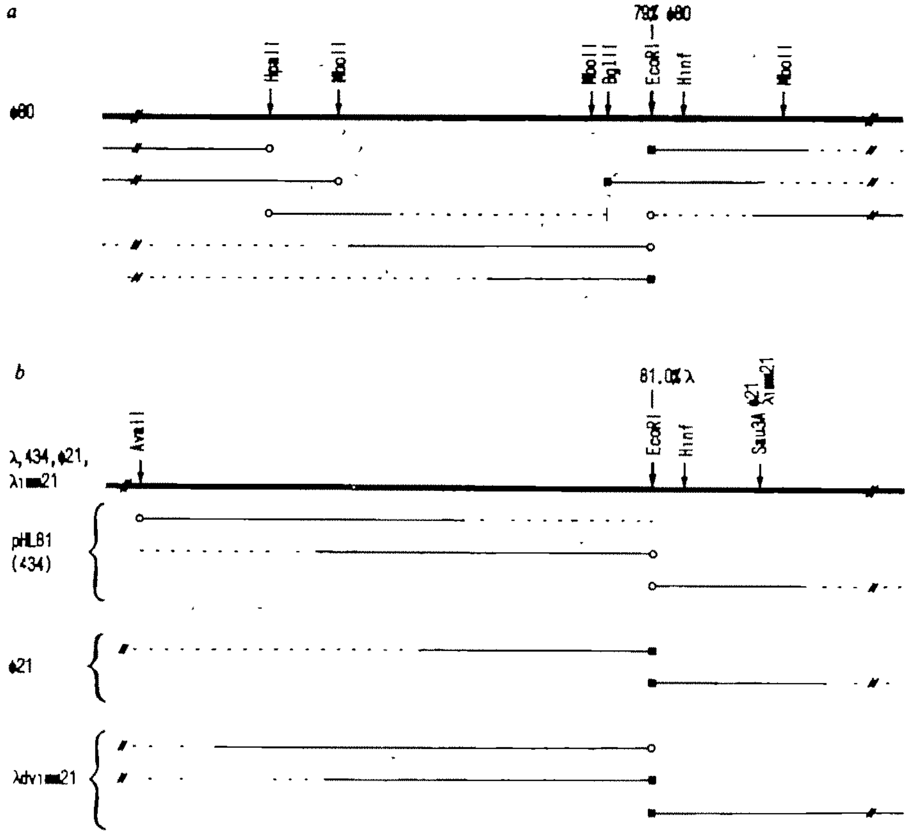

Fig. 1 Physical maps and schematic protocols for the sequence analysis of the ori regions of lambdoid phage DNAs. *a*, Sequence analysis of the *ori*-region of phage φ80 DNA. *b*, Sequence analysis of the *ori*-region of other lambdoid phages. Sequencing was performed with plasmid pHL81 DNA[9], carrying the *ori*-region of phage 434, φ21 DNA, and plasmid λdv*imm*21AB5 DNA[36], carrying the *ori*-region of phage λ *imm*21. Double-stranded DNAs are indicated by double lines, with positions of restriction endonuclease cleavage sites indicated by vertical arrows. Single lines drawn below represent single strands of restriction fragments used for sequencing, each carrying one end labelled. An open circle indicates a labelled 5′-end, and a line extending to the right of the circle, for example, represents the *l*-strand of a fragment used for sequence determination, in 5′- to 3′-direction. A 3′-end labelled is marked by a square. The solid part of each line indicates the portion of the fragment for which unambiguous sequence information could be obtained. A vertical bar shows the secondary restriction site used for cleavage of one of the labelled fragments, while other secondary cleavage sites used lie outside of the region shown. Terminally labelled single strands if obtained by strand separation (for example, the *Ava*II–*Eco*R1 fragment of pHL81–DNA) are not explicitly designated in the drawing

in sequence for λ and φ80 and which do not include such structural symmetries; they probably do not belong to the origin of replication proper. An 8 out of 9 base pair identical sequence in the left tail segment may be coding for an essential element in the O protein structure, because it is read in the same frame: Ser-Glu/Ala-Trp. Only one half of an (additional) inverted repeat sequence is retained within the λ right tail sequence, the second half is located beyond the 202 base pair maximal origin boundaries—this may even be used as an argument against the remaining tail segment's being of any importance.

Conserved length of unique composition in the central region

The central (B) section (λ 1,099–1,135) of the lambdoid origins of replication consists of a stretch of DNA sequence which is uniquely rich in A in the *l*-strand, and in T in the *r*-strand, including an uninterrupted sequence of 15A + 3G in the λ origin DNA, as first observed by F. Blattner and colleagues[5]. While this general characteristic is clearly seen in the φ80 origin DNA, the φ80 sequence is of slightly less extreme composition. There appear to be three segments of identical or nearly identical DNA sequences in a section B λ/φ80 comparison (see boxes in Fig. 3) which may be indicative of their functional importance, but the intervening groups of nucleotides are also rather similar and are identical in length, except for the deletion of one base pair in the φ80 DNA (corresponding to λ : 1,136) at the junction between the origin B and C segments.

In contrast to the flanking regions A and C, the central section of the origin of replication does not contain any inverted repeat sequences with the potential for being folded into single stranded hairpin structures; instead it very characteristically does contain DNA mirror sequences (true palindromes). One of them, in the λ-DNA group, extends over 28 base pairs with a single (λ, φ21) deviation only (considerably disrupted, however, in 434 DNA). It is immediately followed to the left by a second one of 12 base pairs (1 deviation). As a result of several nucleotide exchanges, the very long DNA mirror sequence is not prominent in the φ80 origin of replication DNA; it is in part 'suppressed' by another, perfect 15 base pair mirror sequence, which asymmetrically overlaps with the first. Since an asymmetric DNA composition of the kind observed in section B would contribute to forming such mirror DNA sequences, they can still be maintained to be accidental, and their part in the overall origin function—if any—remains uncertain.

Segments of double-stranded DNA sequence of the composition observed for section B should have very low melting points as a result of their high A–T contents. According to reference data[30] the T_m can be calculated for the λ and φ80 section B DNAs to be about 78.5 °C and 79 °C, respectively (in 1 × SSC; 12 °C below λ DNA average). Specialised sections of such sequence, when their strands become separated in an RNA polymerase catalysed transcriptional activation reaction (see below), should transiently be converted into a rigid, open helical conformation, due to the purine stacking interactions in their separated *l*-strands.

Specific sequences exposed in (protein coated) single-stranded templates are known to be required for binding and initiating primer RNA synthesis by *dna*G coded primase, and the same sequences, if present in double-stranded DNA, will not be recognised by this enzyme[25]. In a λ–colE1 hybrid plasmid genetic analysis a replicational primer synthesis has been observed to be initiated within the origin of replication boundaries in an asymmetric, only right to left orientation, and to be insensitive to an inserted transcriptional terminator[9]. λ replicational primer synthesis, therefore, seems to be catalysed not by RNA polymerase, but most probably by primase, already known to be involved in initiation of DNA replication in other systems[23,24]. The central section of the origin, which coincidentally has a very low melting point, and contains the DNA sequences analogous to the G4 origin[26,27], also in a right to left orientation, seems, therefore, to be the most obvious choice for an initiation site for the λ primer synthesis observed *in vivo*. This is confirmed by the fact that the RNA polymerase is not bound to various φ80 DNA fragments carrying the origin of replication, in a filter binding assay (in 125 mM KCl, 10 mm $MgCl_2$, 20 mM Tris HCl (*p*H 8.0) at 37 °C, with competition by poly(rI) (ref. 31, results not shown). The overall rifampicin sensitivity of λ replication[18,23,24,32] may then have to be attributed to the preceding RNA polymerase catalysed transcriptional activation of the origin structure, usually in a left to right direction across its location.

Asymmetric oligo dA : dT segments have also been observed in other, unrelated double-stranded origins of replication[33], and A-rich sequences for single-stranded phage DNA origins[26,27]. Comparison between their sequences may lead to the identification of a promoter-equivalent primase signal structure.

Two λ origin-defective mutants, in which different parts of section B are deleted (λ *r*99 : 1,098–1,109; λ *r*96 : 1,116–1,130) have been sequenced to date[5]. Both of them show a completely defective mutant character.

Two overlapping DNA hairpin loops in the right-hand section

The origin section C shows two different characteristic organisational features which are both contained in the same stretch of the DNA. One is the exceptional, 31 base pair sequence, which is identical (with two exceptions) for all four phage DNAs. Second, this section contains two almost perfect inverted repeat sequences which overlap asymmetrically. On DNA strand separation the inverted repeat sequences could give rise to two different kinds of DNA hairpin structures (see Fig. 4). These 33 base pairs at the origin of replication (λ : 1,136–ϕ80 : 1,168) therefore apparently have to fulfill triple functions. First they code for 10 amino acids of the gene *O* product, and second and third, they act as parts of the longer and the shorter DNA hairpin loops. DNA segments with multiple functions have also in other cases been shown to be highly conserved throughout evolution[34].

Because the section C sequences are almost identical in all four phages, any candidate initiator protein(s) binding to them must also be identical or at least exchangeable among all four phages. These should, therefore, be the phage P proteins, or one of the host initiators, such as the *dna*B protein (or a complex of both).

If the λ origin of replication is cut within section C at the *Eco*RI restriction site and is fused onto various foreign, *Eco*RI terminated fragments, the overall replicational activity (in the presence of the O protein) will drop to 3–5% of its original value, as observed in the λ–colE1 hybrid plasmid system[9]. This indicates that section C is an integral part of the overall λ replicator structure. The functional leakiness of the deletion variants may be due to either the activity of the remaining fraction of section C DNA, or else may indicate a potentiating rather than a basic function for section C.

DNA cloverleaf structure in the left-hand section

Section A of the lambdoid origins of replication displays the largest number of symmetry elements (Fig. 3). These are organised in the form of direct repeats, which consist internally of an inverted repeat substructure. Also, the direct repeats are very regularly spaced within the section A sequence, and therefore higher orders of symmetry involving several such elements can be considered. All such considerations of structural symmetry originate from the multiple repetitions of a basic sequence 'theme' (boxed in Fig. 3), alternating in direct and inverted orientations. While the λ and ϕ80 linear section A DNA sequences differ from each other, they are organised in a clearly analogous manner with the total and very complex arrays of symmetry elements present in nearly identical arrangements. The sequence 'themes' basic to all of these analogous configurations, however, are different, even in length: λ, 434, ϕ21: GAGGGAT; ϕ80: CGGGAA.

If DNA strand separation is accepted as likely to occur at the origin of DNA replication, any one of the section A inverted sequence repetitions could be folded into a single-stranded DNA hairpin structure, and therefore several 'activated' structural arrangements are possible for a segment of such complex organisation. A collection of potential secondary structures is represented in essence by the arrows drawn in Fig. 3. However, the only one of these potential activated structures which involves all the symmetry elements at the same time, and also makes use of their regular spacing along the DNA of this section, is a DNA cloverleaf arrangement (Fig. 5). Identical superstructures can be drawn for ϕ80 and for λ, in spite of the differences between their individual elements. When folded into such higher order of symmetry arrays, the repeated sequences of either six or seven nucleotides form the individual branches and stems of the cloverleaf structures. Quite consistently, it is also

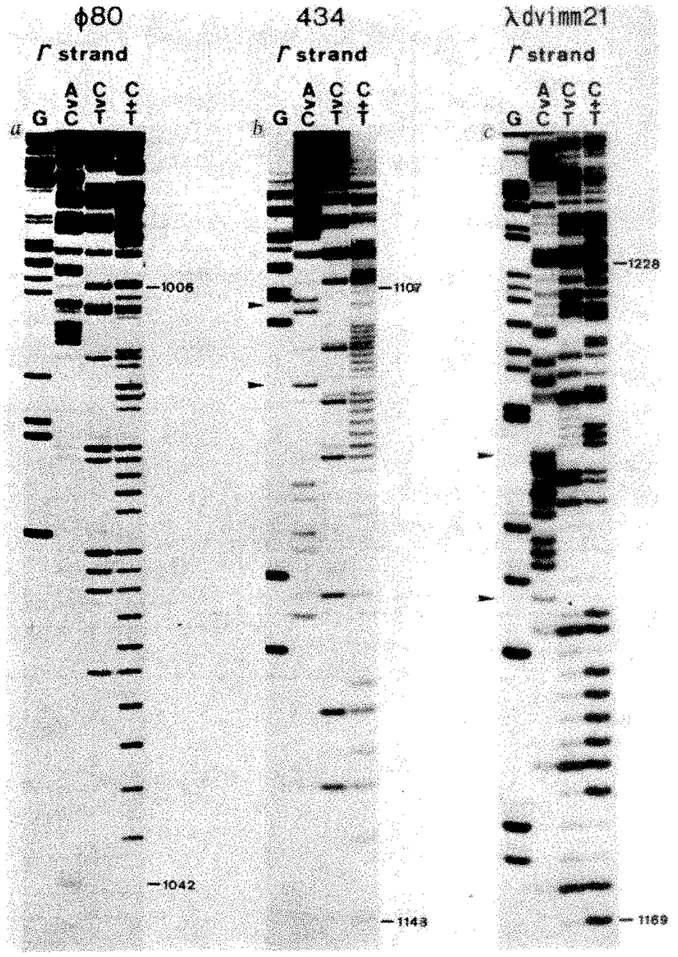

Fig. 2 Autoradiographic patterns of DNA sequencing gels after electrophoretic separation of the chemical degradation products of various origin DNA restriction fragments. The lanes designated by G, A > C, C > T, and C + T display the products of the corresponding reactions. DNA fragments derived from the various origin of replication regions as observed in preceding restriction mapping have been terminally labelled with ^{32}P-phosphate at either their 5′-ends by using polynucleotide kinase and [γ-^{32}P] ATP (ref. 29) (*a*–*b*) or at their 3′-ends by DNA polymerase I and [α-^{32}P]dATP (refs 37, 38)(*c*). For DNA sequencing the dimethylsulphate/hydrazine technique[29] has been used throughout this work. The numbers to the right of each gel refer to the corresponding nucleotide positions in the *l*-strand DNA sequences shown in Fig. 3, while arrows to the left (in *b* and *c*) indicate some of the sequence deviations in the *ori* regions of pHL81(that is, phage 434) DNA (*b*), and λdv*imm*21AB5 DNA (*c*), with respect to the homologous λ DNA sequence[6]. The deviations in the *ori* region of λdv*imm*21AB5 DNA could also be observed in ϕ21 DNA (compare legend to Fig. 3). *a*, Sequence pattern obtained from the 5′-labelled *Mbo*II fragment 338–1,046 derived from ϕ80 DNA, which was recut by *Hae*III at position 892. *b*, Sequence pattern from the 5′-labelled *Eco*RI fragment of pHL81 DNA (434 DNA) 624–1,146, recut by *Bgl*II at position 792. *c*, Sequence pattern from the *Eco*RI-linearised, and at position 1,146 3′-labelled λdv*imm*21AB5 DNA, recut by *Taq*I at position 1,466. The degradation products were loaded on 40 × 22 × 0.2 cm gels (*a* and *b*) or 90 × 16 × 0.2 cm gels (*c*) of 20% polyacrylamide/7 M urea, and were electrophoresed for 6 h at 1,000 V (*a* and *b*), or for 24 h at 2,000 V (*c*).

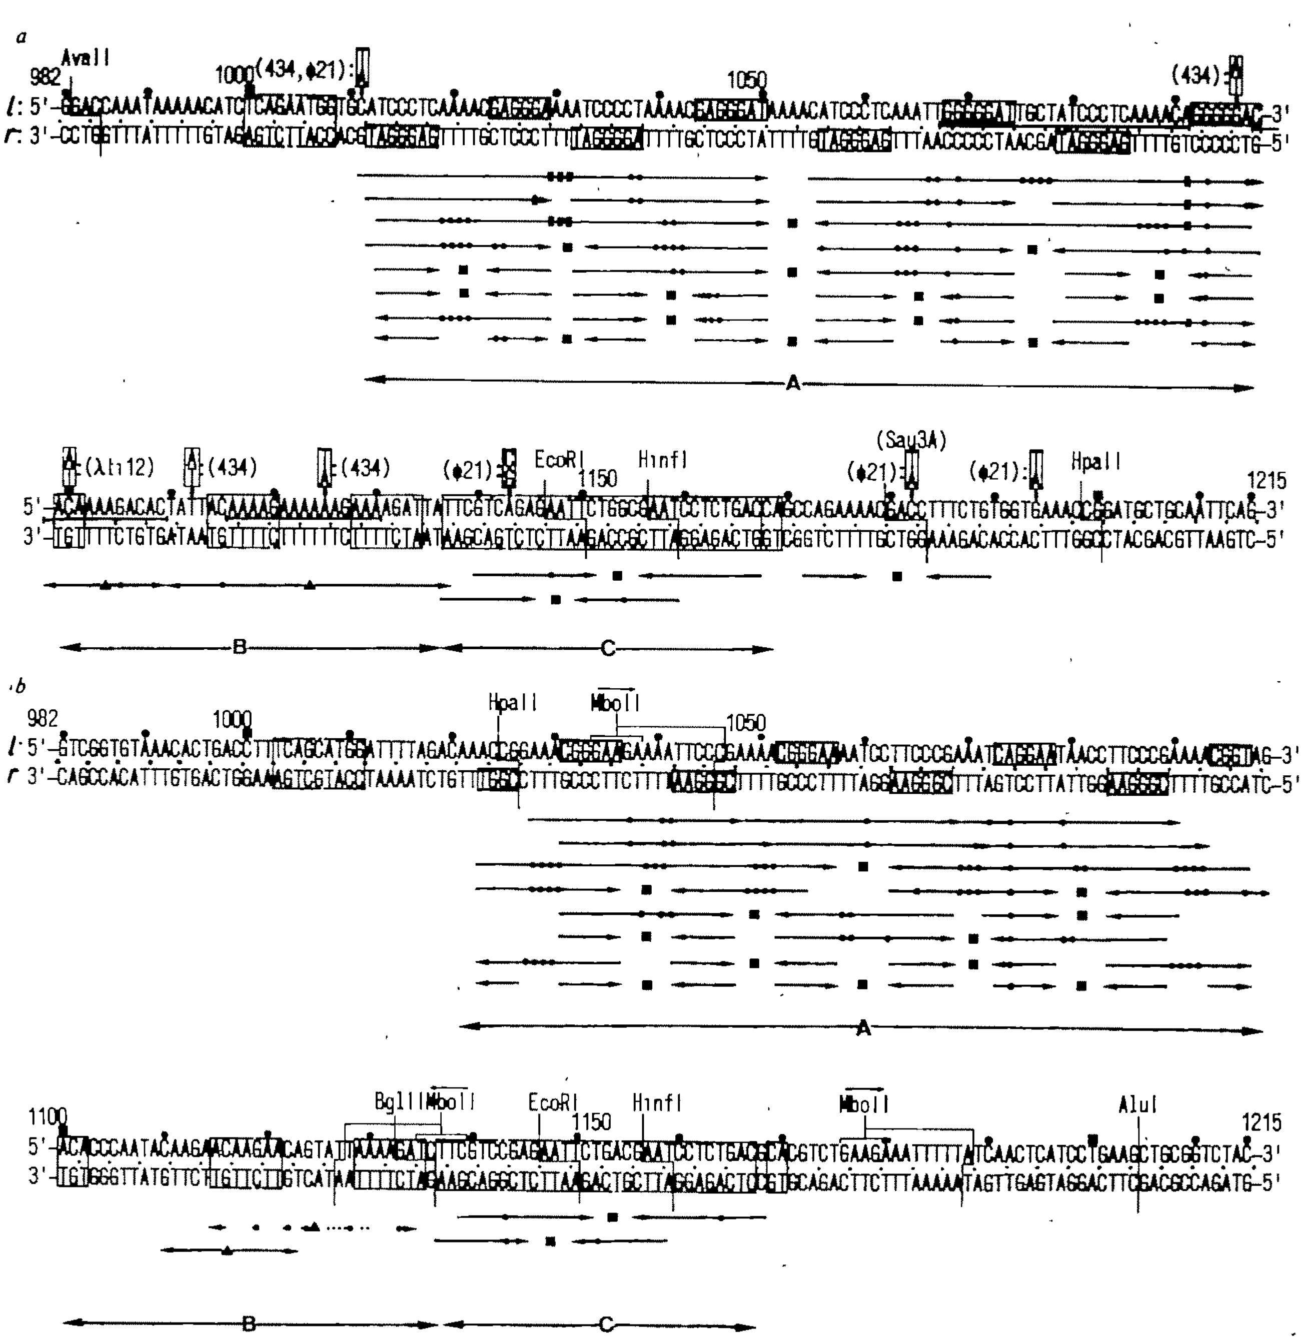

Fig. 3 DNA sequences of the λ (*a*) and φ80 (*b*) origins of replication in the λ (φ21) minimisation boundaries (982–1,182) (ref 9). The nucleotide positions in all four phage DNAs are normalised, for 1,146 to indicate the first nucleotide (G) of the common *Eco*RI cleavage site located within their origin of replication sequences This is equivalent to position 1 indicating the first nucleotide transcribed into the p_R promoted mRNA, in λ DNA[37]. Nucleotide exchanges observed for the homologous 434 and φ21 DNA in an otherwise identical sequence are indicated above the λ sequence, the position 1,100 transversion determined for the λ *ti*12 mutation[6] has also been included. Selected restriction endonuclease cleavage sites are referred to in their standard abbreviations. The *O* gene reading frames are marked by dots between the two lines showing the DNA sequences for both complementary strands, and the nucleotide segments deleted in three λ *ori*⁻ deletion mutants[3] are also indicated (———)· reading from left to right, λ *r*93, λ *r*99 and λ *r*96. Double strand boxes mark segments of λ/φ80 DNA homology, single strand boxes point out multiply repeated sequence 'themes' present in the left sections The symmetry elements observed in the origin DNAs are indicated below the sequences. Direct repeats have been marked by repetitive arrows, inverted repeats by two arrows pointing towards their inversion centre (square), the arrows indicating a mirror DNA sequence have been orientated away from its centre (triangle). G · T/A · C symmetry deviations in inverted repeats have been indicated by one dot (in the *l*-strand purine location), A G/T · C mismatches by two dots (in both locations), vertical bars in *a* mark positions of nucleotides inserted or deleted over a perfect match. In the left parts, the lower-most arrangements of symmetry elements correspond to the activated DNA cloverleaf structures presented in Fig. 5 Three structurally different sections of the origin sequences as deduced from the distribution of symmetry elements are indicated at the bottom (A, B, C). In comparing the origin DNA sequences of λ, φ21 and hybrid λ *imm*21 DNAs (plasmid λdv*imm*21AB5 (ref. 36), and phage λ *imm*21 (ref. 11)) we observed that the hybrid λ *imm*21 DNA in this region consists of φ21 rather than λ DNA. This has been concluded from the presence of the exchanged φ21 nucleotides instead of the λ specific nucleotides at every divergent position analysed. 1,011, 1,143, 1,182, 1,194 (and 1,233, not shown) The nucleotide exchange C→T at position 1,182 results in an additional *Sau*3A recognition site not present in λ DNA, which has been used in our origin minimisation cloning studies[9] Therefore, the origin limits as indicated are actually those of φ21 DNA, which however should also apply to the nearly identical λ DNA Restriction analyses of φ21 and λ *imm*21/λdv*imm*21 DNAs in comparison with the λ DNA *O* and *P* gene sequences (ref. 6 and E Schwarz, unpublished) resulted in recognition of a number of restriction sites present in both φ21 and λ *imm*21 DNA, but not present in λ DNA, up to at least the centre of the *P* gene. Only to the right of the *P* gene is the λ *imm*21 DNA like λ DNA (not shown). λ *imm*21 and φ21 DNA have also been sequenced and compared to λ DNA in the *oop* and p_0 promoter regions[6], and in this segment, to the right of the 'λ *imm*21 boundary' at position 595 (ref 37) all three DNAs are identical for at least 117 base pairs From these results we wish to conclude that the recombination event leading to λ *imm*21—(ref. 11) took place near the right rather than the left end of the *oop-O-P* homologous section of λ compared with φ21 DNA. While position 595 now may have to be called a 'virtual boundary' with respect to the λ *imm*21 creation event, it can still be expected to mark the effective boundary of non-homology compared with homology in a phage λ *imm*21/λ recombination or DNA heteroduplex analysis.

the most complex cloverleaf configuration, which results in the smallest number of hairpin mismatches (Fig. 3). This is particularly obvious for the altogether smaller (77 base pair compared with 85 base pair), and most perfect $\phi 80$ DNA cloverleaf, which in all of its three hairpin branches only contains a single A · C/G · T (*l*-strand/*r*-strand) mismatch, due to an aberrant A:T instead of G:C in position 1,074.

The potential λ, 434, and $\phi 21$ DNA cloverleaf structures have their branches and stems expanded over the $\phi 80$ DNA cloverleaf size by one hairpin base pair each. Although this should add to their stability, they do include an increased number of mismatches (three within the branches, one or two within the stem, all of the G · T/A · C type, and some other deviations concerning the left branch). Some of these aberrations may result from amino acid sequence requirements in that part of the O protein structure, for which the origin DNA sequence is coding in addition to its fulfilling DNA replicator functions.

Besides yielding nearly perfect cloverleaf branches only the origin cloverleaf model also succeeds in placing all the four regular, significantly A-rich intervening sequences into a specific, symmetrical arrangement of their own ('connecting stretches', $\phi 80$: AAAA, λ : AAAAN, with few deviations only). Stacked A_4 groups in between the cloverleaf branches are supposed to aid in lining up the protein-complexed individual cloverleaf elements for tetramerisation. The three more variant intervening groups which generally consist of A-rich, pentanucleotide sequences, through cloverleaf folding become located into symmetrical positions of their own too, and form the single-stranded top loop sequences of the individual branches. Both groups are necessary parts of the overall cloverleaf structure, in addition to the cloverleaf branches proper. Obviously, the cloverleaf stems because of their external connections have to deviate somewhat from a regular cloverleaf branch configuration. They are still close enough in their structural arrangements, however, to qualify for a fourth branch of the section A DNA cloverleaves (more fully in the λ case).

An additional point favouring the hypothesis of a higher order DNA cloverleaf structure is that it can be built from small, individual hairpin loops used as building blocks, which are then converted into a large superstructure, through a secondary, symmetrical rearrangement (of protein subunits bound to them). In our model to explain the mechanism of transcriptional activation of the origin of replication we expect RNA polymerase to act as a DNA strand separation agent which is able to catalyse the formation of such hairpin loops within the non-coding strand, while both strands during transcription are being separated internally in the enzyme molecule[28]. Only rather short DNA hairpin loops, however, are likely to be accommodated by the enzyme molecule in such a mechanism, and activated origin structures using larger-sized individual DNA-hairpin configurations[5] (which in the middle also would contain rather weak sections, see Fig. 3) seem to be disfavoured in this kind of an activation reaction, while a stepwise formation of individually activated cloverleaf branches would be possible.

We interpret an activated section A origin cloverleaf structure to represent the single-stranded (tetramer) DNA binding site for one of the proteins active in initiation of phage DNA replication. As judged from their analogous, but individual DNA structural designs, the initiator proteins binding to the $\phi 80$ or λ DNA cloverleaves should also be analogous, but different and non-exchangeable between the two phages (exchangeable, however, within the group of λ, 434, and $\phi 21$). The obvious choices for proteins of such specificity have to be the O proteins of all these four phages, or more precisely their N-terminal domains[17]. The design of the DNA cloverleaf structures seems to predict their binding of four identical O protein subunits, each of which may capture one of the RNA polymerase activated cloverleaf branches (as indicated in Fig. 5 in a rather general way). The DNA bound protein tetramer in turn is expected to aid in stabilising the overall DNA–protein conformation through protein–protein interactions. With an activation complex (sections A–C) first installed in the non-coding, A-rich *l*-strand, the complementary *r*-strand would stay single-stranded, and therefore would have a chance of also being converted into protein-complexed secondary structures, even without a special activation mechanism of its own. While a cloverleaf activated state structure of the origin section A DNA (on its own) would be clearly less stable than its double-stranded ground-state conformation, the energy to be contributed by a cloverleaf DNA–initiator protein binding reaction, in order to compensate for the formation of single-stranded sections within this structure, has been calculated to amount to not inaccessible values for the protein subunit–cloverleaf branch interaction compared with other protein–DNA binding reactions.

One of the origin defective mutants, λ *r*93, has been shown to delete 24 base pairs (1,068–1,091) of the section A DNA (ref. 5), which if projected upon the λ cloverleaf model would correlate with exactly its right branch and lower right connecting stretch removed. The observation of a slight degree of replicational leakiness for λ *r*93 (ref. 4), conceivably might not be in disagreement with a four-branch cloverleaf model, assuming a very low rate of activity for a crippled, strained three-branch cloverleaf that might be formed in that λ *ori*⁻ mutant. The

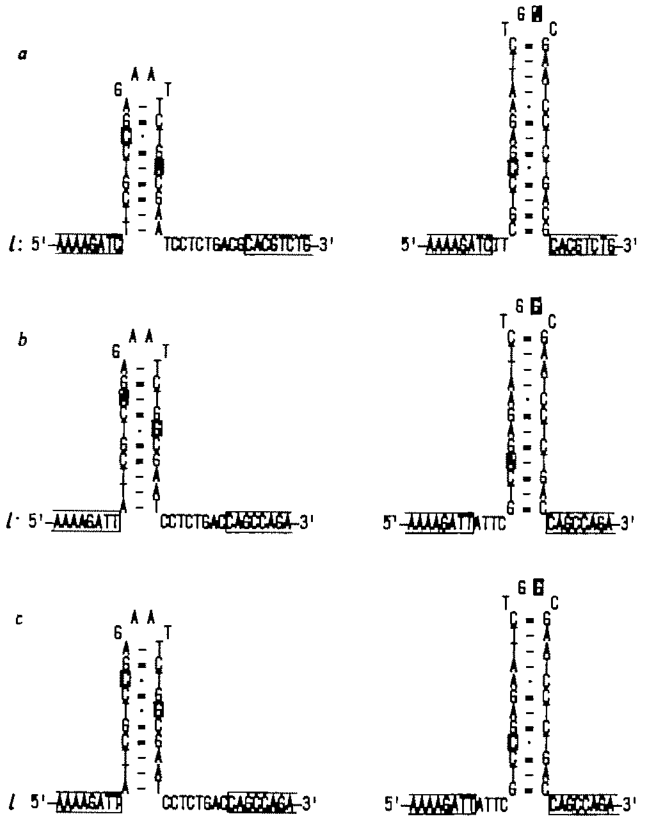

Fig. 4 Potential *l*-strand hairpin loop structures observed in the origin section C DNA sequences of $\phi 80$ (*a*), λ; 434 (*b*) and $\phi 21$ (*c*). The smaller section C DNA hairpin loops (left) are asymmetrically overlapping with the larger section C hairpin loops (right). Left and right external boxes indicate the boundaries of section B, and right tail neighbouring DNA segments, respectively; internal boxes mark the only two positions of single nucleotide exchanges among the various phage DNAs. The left end of the smaller hairpin loop coincides exactly ($\phi 80$: 1,137) or nearly exactly (λ : 1,136; the corresponding base pair, however, is deleted in $\phi 80$) with the left end of the common, identical 31 base pair segment, while the right end of the larger hairpin loop again coincides exactly (λ. 1,167) or nearly exactly ($\phi 80$·1,168) with the right end of the 31 base pair segment. We regard a structurally arranged potential for two rather than one, asymmetrically overlapping, both nearly perfect DNA hairpin loops (within a sequence also coding for a protein), and coincident with a stable, landmark section of general lambdoid origin homology, to be highly significant. And since both the DNA hairpin structures therefore may be of functional importance for the origin DNA C section, we are led to assume that this part of the structure may be shuttling between two different conformations of an activated DNA single-stranded state (and the ground state of double-stranded DNA structure). It has been possible to isolate an *SrI*⁰ mutation for the *Eco*RI recognition sequence at 81.0% (ref. 39); the nucleotide exchange(s) involved are, however, not yet known

Fig. 5 Model proposed for the activated state structures of the ϕ80 (*a*), and λ, 434 and ϕ21 (*b*) origin of replication DNAs Only the restriction cleavage sites limiting the λ (ϕ21) origin in its maximum functional size are indicated; for inverted repeat and DNA mirror sequence symbols see Fig. 3 Segments of ϕ80/λ DNA homology are marked by boxes, segments of ϕ80/G4 and of λ/G4 DNA homologies in the central origin sections are indicated by lines above the *l*-strand sequences, with dots pointing out mismatch positions (G4, 170–172, 175–180, and 183–202 (ref. 26)). Four subunits of the (O) proteins supposed to be binding to the origin cloverleaf DNA structures have been indicated in a rather general way. Mismatches in the section A cloverleaf branches, and in the section C (larger) hairpin stems are marked by dots.

analysis of a λ *r*93 pseudorevertant DNA has shown the deleted section A sequence not to be re-installed[35], and therefore proves the λ *r*93 defect not to be due to the loss of the indicated segments as such, but to the disruption of an origin superstructure, of which these section A sequences are a constituent part. In replication-defective λ *ti*12 (ref. 3) a transversion at position 1,100 (ref. 6) points out the only single nucleotide so far known to be of functional importance. Quite consistently, in constructing the two different DNA cloverleaves, the constant ACA group surrounding this position had to be placed into an identical situation with respect to both structures, as in fact both of the cloverleaves are located almost exactly in register with respect to the central sections, or to the section C DNA hairpins (36 compared with 35 base pairs for the smaller, 39 compared with 37 base pairs distance for the larger section C hairpins).

It is certainly obvious that our model for the activated, single-stranded functional structure of the lambdoid origin of replication as deduced from DNA sequences and from genetic studies[9], needs to be studied further biochemically, both *in vivo* and *in vitro*. However, sandwiching of a primase recognition site which is kept in a single-stranded, rigid conformation by two different initiator proteins, which in turn are complexed to two adjacent, elaborate DNA binding sites, seems to be able to explain both the basic structural as well as functional designs of such replicator signal elements.

We thank J. Gross for computer programming. G. Schlingmann for technical assistance, and H. Klump, H. Kössel, M. Lusky, H. Schaller, G. Scherer, and E. Schwarz for valuable discussions, and for criticising the manuscript. This work has been supported by the Deutsche Forschungsgemeinschaft.

Domains and the hinge region of an immunoglobulin heavy chain are encoded in separate DNA segments

Hitoshi Sakano, John H. Rogers*, Konrad Hüppi, Christine Brack, André Traunecker, Richard Maki, Randolph Wall* & Susumu Tonegawa

Basel Institute for Immunology, 487 Grenzacherstrasse, Postfach, CH-4005 Basel, Switzerland and *Molecular Biology Institute and Department of Microbiology and Immunology, School of Medicine, University of California, Los Angeles, California 90024

A 6.8-kilobase DNA fragment containing the sequence coding for the constant region of the mouse immunoglobulin γ_1 heavy chain was cloned from total cellular DNA. Electron microscopic and nucleotide sequencing studies showed that the three protein domains and the hinge region are encoded in separate DNA segments.

SOME higher cell genes consist of informational DNA interspersed with silent sequences. Eukaryotic cistrons are often transciption units containing alternate regions to be excised from the primary transcript, introns, and to be left in the mature messenger RNA for expression, exons[1]. The first indication of such a mosaic gene structure was obtained in the 28S ribosomal RNA gene of *Drosophila melanogaster*[2,3]. This observation was followed by discoveries of an intron within the RNA leader regions of the human adenovirus late genes[4,5]. Introns were also found in the protein-encoding regions of mouse immunoglobulin λ-chain genes[1,6], rabbit and mouse β-globin genes[7,8], hen ovalbumin genes[9,10], and in yeast tRNA genes[11,12]. More examples are accumulating. These studies show that introns are widespread in higher cells and their viruses, but the functions and origin of introns remain unclear.

Both light and heavy chains of immunoglobulin molecules consist of two functionally differentiated regions: the amino terminal variable (V) region and the carboxyl terminal constant (C) region. The V region recognises and binds antigens while the C region exerts various effector functions such as interaction with cell surface membrane and complement. Amino acid sequence studies have shown that both light and heavy chains consist of homology units[13,14]. For instance, the C region of a γ-class heavy chain contains three homology regions, CH1, CH2 and CH3, each of which is similar in size (about 110 residues) and homologous to the C region of a light chain[15]. Furthermore, the V regions of both light and heavy chains may also be related to the C region based on the arrangement of intrachain disulphide bonds and their size, and the presence of a

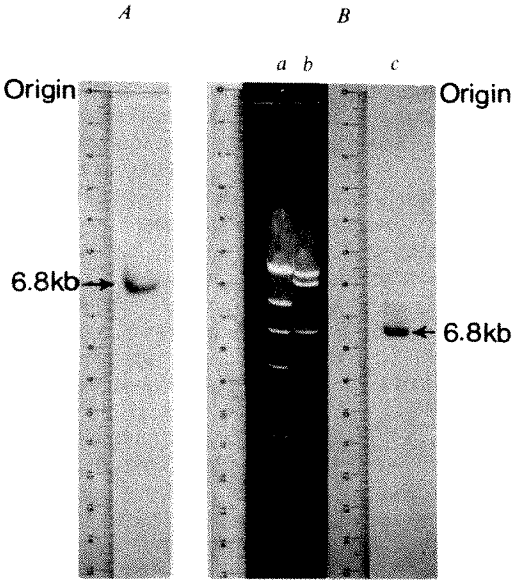

Fig. 1 Southern hybridisation of pH21-1 cDNA to myeloma MOPC 21 or cloned IgCγ_1-1 DNA. *A*, 2 mg of high molecular weight DNA extracted from myeloma MOPC 21 was digested to completion with *Eco*R1 and separated on 0.8% horizontal agarose gel slab (20×40×1 cm) in TA buffer (40 mM Tris-HCl, 5 mM Na-acetate, 1 mM EDTA, *p*H 7.9) at a constant current of 50 mA for 4 days. To detect the γ_1 gene-positive DNA fragments, a 0.5-cm wide section of the gel was cut out from the centre in parallel with the direction of electrophoresis, and was blotted onto a nitrocellulose filter (Schleicher-Schuell, BA85) for 3 h as described by Southern[20]. The filter was incubated at 65 °C for 12 h in the presence of 2×10^7 c.p.m. of denatured, nick-translated pH21-1 cDNA (specific activity 2×10^8 c.p.m. per μg) as described elsewhere[19]. The figure shows an autoradiogram of the filter after 6 h of exposure. The molecular size of the γ_1 gene-positive band was estimated from its relative electrophoretic mobility to *Hin*dIII fragments of phage λ DNA. For the cloning, DNA was recovered from the preparative slab gel as follows. Hydroxyapatite (Bio Rad, DNA grade) washed with TA buffer was mixed with an equal volume of 0.8% melted agarose (in TA buffer) and the mixture was poured into the 0.5-cm wide vertical slot in the centre of the gel slab and into a parallel slot of 0.5-cm width located near one edge of the gel. The gel slab was rotated 90° and electrophoresis was continued at 150 mA for 4 days to let DNA fragments migrate into and bind to the embedded hydroxyapatite. Hydroxyapatite containing γ_1 gene-positive DNA fragments was identified from the autoradiogram of the Southern gel blot, and a 0.5-cm thick slice of the hydroxyapatite cake in this region was cut out. The slice was suspended in 1 ml of saturated KI solution and heated at 65°C for 15 min to melt the agarose. The hydroxyapatite was collected by centrifugation and was washed with 3 ml of 10 mM KPO_4 buffer (*p*H 6.9). The DNA was eluted from the hydroxyapatite with 0.5 ml of 0.6 M KPO_4 (*p*H 6.9) buffer and the hydroxyapatite was removed by centrifugation. The DNA was dialysed against 10 mM Tris-HCl *p*H 7.9 containing 1 mM EDTA and was concentrated by ethanol precipitation. *B*, 0.5 μg of cloned Ig Cγ_1-1 DNA was digested with *Eco*RI, separated in a 1% agarose gel and stained with 0.5% ethidium bromide (lane *b*). DNAs were transferred onto nitrocellulose filter and hybridised with 2×10^6 c.p.m. of nick-translated pH 21-1 cDNA (2×10^8 c.p.m. per μg) (lane *c*). *Hin*dIII-digested phage λ DNA (0.5 μg) was separated in the same gel as a size marker (lane *a*). The third largest *Hin*dIII-λ fragment is 6.6 kilobases long.

weak homology between these regions[13,15]. These studies suggested two important points on the structure and evolution of immunoglobulin molecules. First, homology regions may have similar three-dimensional structures, each consisting of a compact globular domain. This hypothesis was directly confirmed by X-ray crystallography[16,17]. Second, the presence of the internal homology suggested that both light and heavy chain genes evolved by duplication of a primordial gene that codes for a polypeptide chain with a size of a single homology unit[13]. Our previous studies on λ and κ light chain genes demonstrated that the V and C domains are encoded in separate exons[6,18,19]. We here report that the three C region domains of mouse γ_1 heavy chain as well as the chain-linking hinge region between the CH1 and CH2 domains are encoded in separate DNA segments.

Identification and cloning of an *Eco*R1 fragment carrying a Cγ_1 gene

High molecular weight total cellular DNA extracted from MOPC 21 myeloma was digested to completion with *Eco*R1 and the resulting DNA fragments were analysed by the Southern gel blotting technique[20] using as the hybridisation probe a nick-translated cDNA clone (pH21-1) prepared from MOPC 21γ_1 chain mRNA. As shown in Fig. 1*A*, we detected a single band of 6.8 kilobases that hybridised with the cDNA probe. Rogers *et al.* sequenced the γ_1 cDNA and found that it contains sequences coding for part of the Cγ_1 region that extends from amino acid residue 287 to 439[21]. We conclude that the 6.8-kilobase *Eco*R1 fragment contains at least part of the Cγ_1 DNA sequence.

DNA fragments in the 6.8-kilobase fraction were recovered from the preparative agarose gel and were ligated with the isolated DNA arms of an EK-2 vector, phage λgt WES[22]. The recombinant DNAs were packaged *in vitro* into phage coats[23] and plaques were screened by *in situ* hybridisation using the nick-translated Cγ_1 cDNA clone as probe[24]. Screening of about 2×10^5 independently arising plaques lead to the identification of eight positive clones. When digested with *Eco*R1, DNA from the eight phage clones gave, in addition to the left and the right DNA arms of the vector, a 6.8-kilobase DNA fragment that hybridised with the Cγ_1 cDNA probe. The results of one of the eight phage clones, IgCγ_1-1, are shown in Fig. 1*B*.

Table 1 Length measurements of R-loop molecules

Segment	Length (kilobases)	*N*
A	3.29±0.13	48
B	1.92±0.12	68
R1	0.28±0.05	64
R2	0.34±0.05	53
R3	0.42±0.08	60
I1	0.51±0.09	45
I2	0.18±0.03	14
I1a	0.37±0.06	29

The R-loops R1–R3 were measured in double-stranded molecules, in which the intervening sequence I_1 was stretched out or seen as an intron-loop, and I_2 was seen only in stretched out molecules (Fig. 2*b*). In the single-strended DNA–mRNA hybrids the intron I_{1a} is shortened because of the annealing of the hinge coding region. I_{1b} is not measurable, but probably is about 100 base pairs long. The hinge region must be within 140 base pairs from the 5′ end of the R2 coding region. Values are given ±s.d. *N*, numbers of measured molecules. Measurements of R-loop molecules were made with a Numonics digitiser and the data analysed with a Hewlett Packard HP9825 calculator.

The Cγ_1 gene is split

The position of the Cγ_1-coding region in the 6.8-kilobase DNA fragment of the IgCγ_1-1 clone was determined by electron microscopy. R-loop molecules were formed between the cloned DNA and a γ_1 chain mRNA purified from MOPC 21 myeloma cells[25]. Figure 2 shows the various R-loop structures observed. Most of the molecules have three small R-loops, R1, R2 and R3, that are separated by two double-stranded intervening DNA segments (I1 and I2) (Fig. 2*a*). In all molecules a short RNA tail could be observed at the largest R-loop (R3), and in some molecules a longer RNA tail extends also from the shorter R-loop (R1).

The sites of R-loops and intervening DNA segments are summarised in Table 1. The intervening DNA segment between R2 and R3 (I2) is very short and cannot be visualised as a clear double-stranded loop, rather it appears as a little knob separating the two R-loops. The length of the two intervening DNA segments can best be measured in those hybrids where several mRNA fragments have annealed to the same DNA fragment (Fig. 2*b*, *c*). The lengths of R1 (280 base pairs) and R2 (340 base pairs) roughly correspond to the size of a DNA segment coding for a single domain (100–120 residues) of an immunoglobulin chain, while the length of R3 (420 base pairs) is slightly larger. We interpret the various parts of the observed R-loop structure in the following way. R1 and R2 correspond to the DNA segments coding for the CH1 and CH2 domains, respectively, while R3 probably encodes the CH3 domain and the presumed 3′-untranslated region of γ_1 chain mRNA. This interpretation is supported by the length and the location of the two RNA tails observed in the intact R-loop structure (Fig. 2*a*). The short (~200 bases) and the long (~400 bases) RNA tails can be interpreted to represent the poly A and the V-coding sequence at the 3′- and the 5′-end of the mRNA.

Correlation between exons and the domain- and hinge-coding DNA segments

In order to confirm the interpretation of the R-loop structure described above, we constructed a restriction enzyme cleavage map of the IgCγ_1-1 clone and determined the nucleotide sequences of the relevant regions (Fig. 3*b*, *c*).

In determining the nucleotide sequences we first concentrated on the five regions (indicated in Fig. 3*c* as I, II, IV, V, and VI) that cover the ends of the three major exons. In so doing we discovered that coding at the right end (see Fig. 3*c* for orientation) of exon 1 and the left end of exon 2 leaves about 13 amino acid residues around the hinge region (Fig. 3*d*) unaccounted for. DNA sequencing revealed an additional exon (exon H) that codes for this cysteine-rich region within the 0.5-kilobase DNA segment separating R1 from R2. Electron micrographs of single-stranded DNA-mRNA hybrids (Fig. 2*d*, *e*) are consistent with the presence of exon H. When γ_1 mRNA was hybridised to denatured IgCγ_1-1 DNA, it annealed to the hinge region, thus forming another short intron I1b that is similar in size and appearance to I2. We thus call the four protein-encoding DNA segments exon 1, H, 2 and 3, and the three non-coding intervening DNA segments intron B, C and D as indicated in Fig. 3*c*. We also call the non-coding DNA segment to the left of exon 1 intron A because we anticipate the presence of another short exon further upstream (that is, towards the left in Fig. 3) that codes for the V–C junction region (J region)[18] in analogy to the structure of a λ light chain gene.

The DNA sequences in the six regions (I–VI) indicated in Fig. 3*c* are shown in Fig. 4. Also shown in Fig. 4 are part of the amino acid sequences of MOPC 21γ_1 chain as determined by Adetugbo[26], and the nucleotide sequences predicted from the amino acid sequence. Coding in exon 1 begins with Ala at residue 121 and ends in Val at residue 215. Coding in exon H starts with the Val and ends in Val at residue 228. Coding in exon 2 starts with the Val codon and ends in Gly at residue 335. Finally, coding in exon 3 starts with the Gly residue. The entire

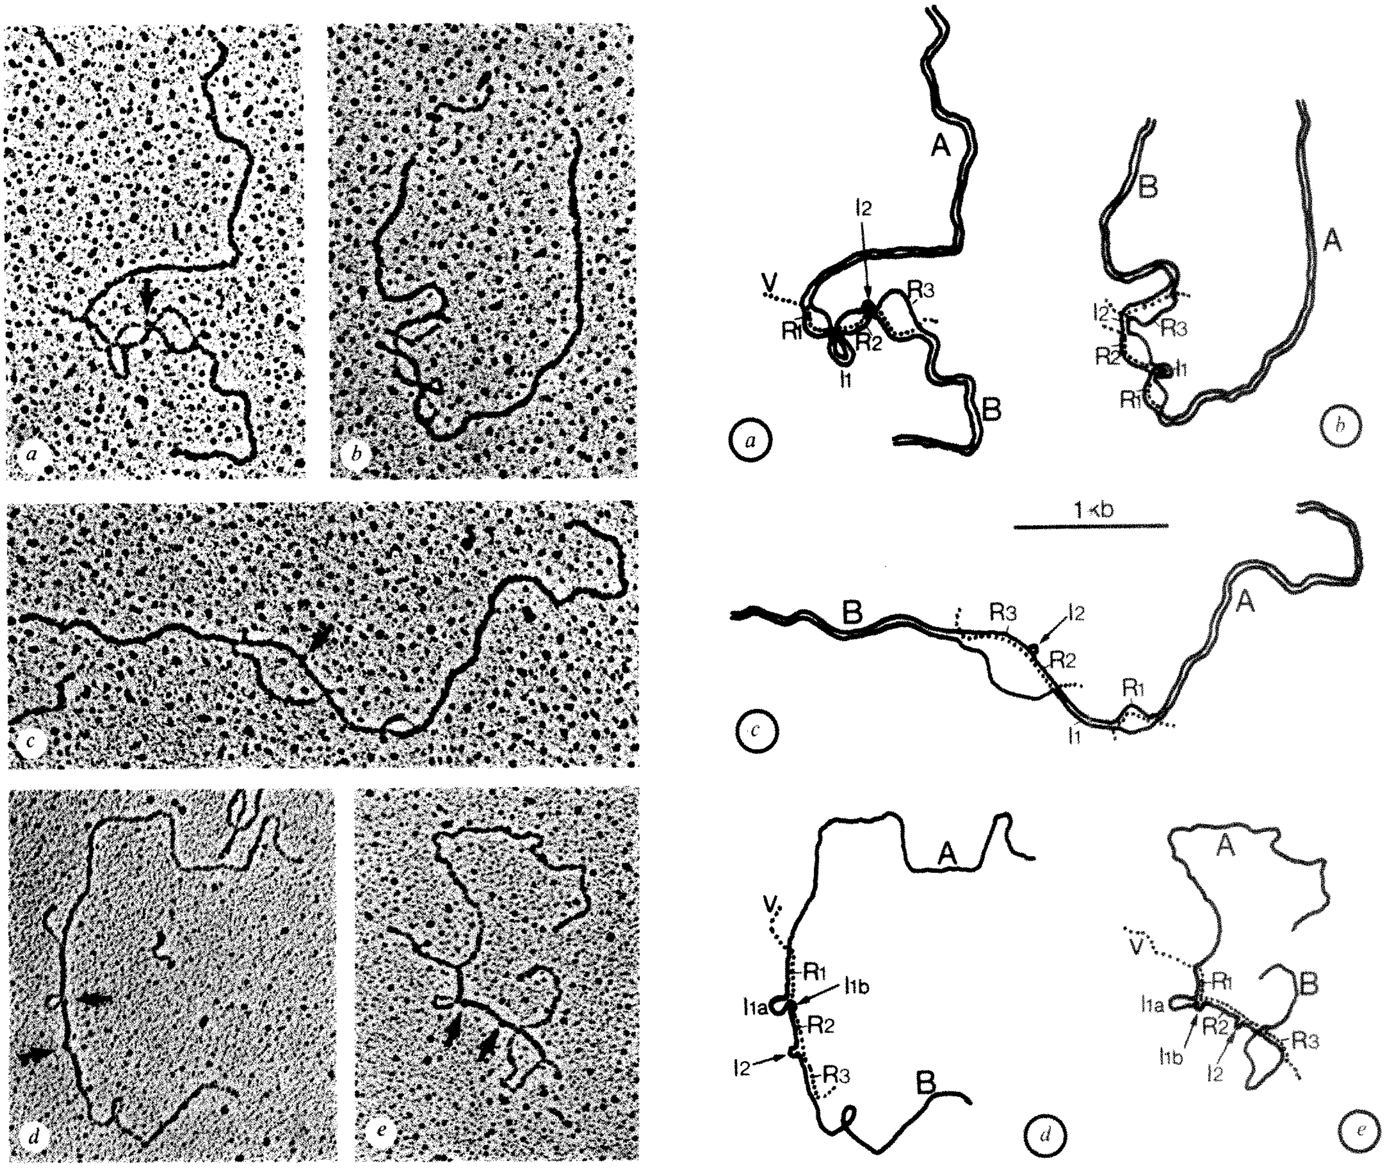

Fig. 2 Left: electron micrographs of R-loop molecules (*a*–*c*) and RNA–DNA hybrids (*d*, *e*). The *Eco*RI-digested IgCγ_1-1 DNA was incubated with MOPC21 γ_1 mRNA under R-loop conditions at 57 °C[18]. Single-stranded DNA–mRNA hybrids were formed after heat denaturation and incubation of the R-loop mixture at 60 °C. The molecules were mounted for electron microscopy by the formamide-cytochrome *c* spreading method[40,41]. Three R-loops R_1, R_2, R_3 are separated by two intervening sequences I_1 and I_2. When two separate mRNA molecules hybridise to different R-loops, the intervening sequences are stretched out and can be measured (*b*, *c*). In single-stranded hybrids (*d*, *e*) it is possible to resolve also the small intron I_{1b} which separates the hinge coding region from the intron I_{1a}, and which appears as a small knob beside I_{1a}. Right: schematic interpretation of the hybrid molecules.

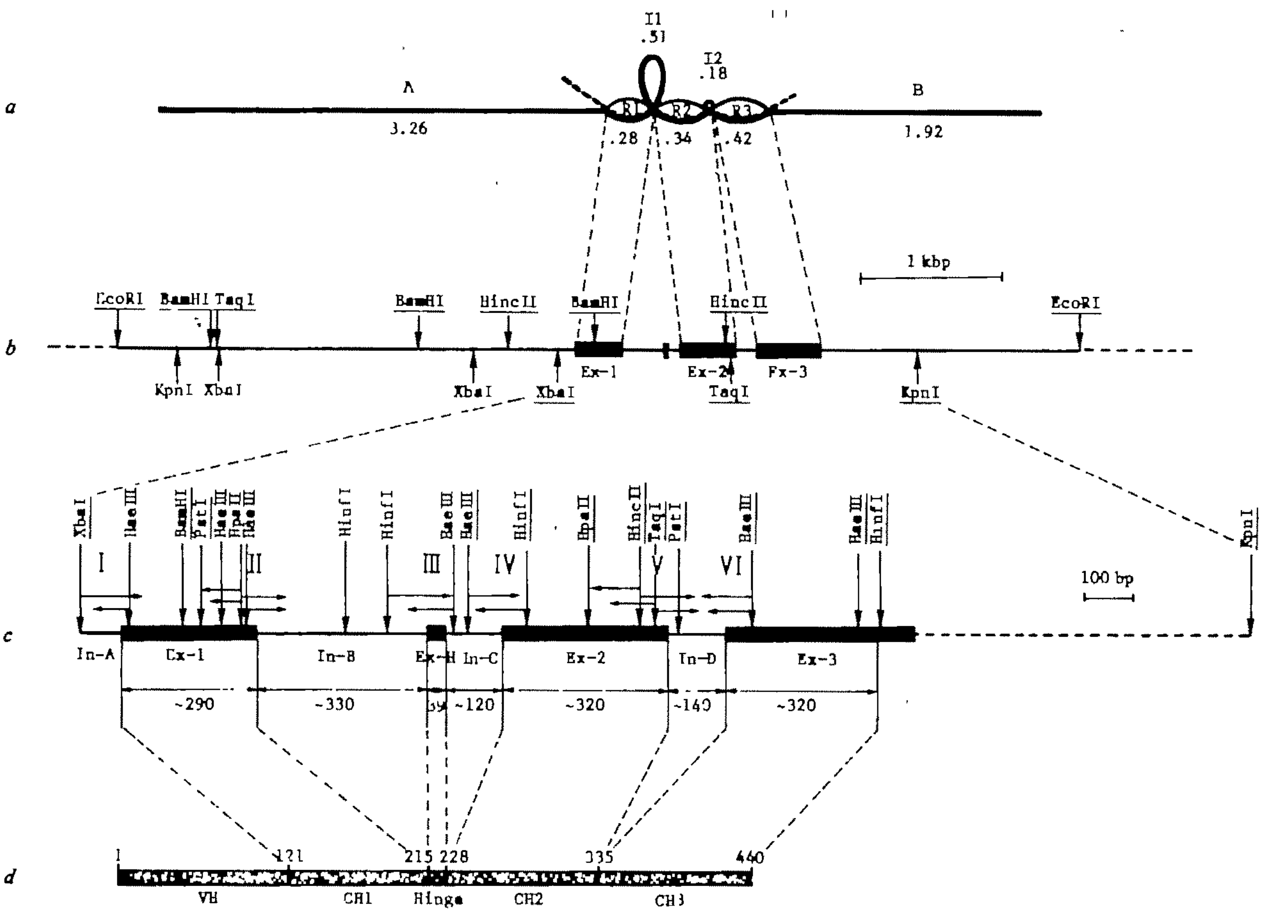

Fig. 3 *a*, R-loop map of the 6.8-kilobase insert. Heavy broken lines and heavy solid lines represent MOPC 21 γ_1 mRNA and double-stranded DNA, respectively. Duplexes between fine solid lines and broken lines are DNA–RNA hybrids. Fine solid lines are replaced single-stranded DNA The numbers indicate lengths of various parts in kilobases. *b*, A map of the 6.8-kilobase insert obtained by the combination of restriction enzyme digestion and R-loop formation. The whole IgCγ_1-phage DNA was digested either with one of the indicated enzymes or with that enzyme plus *Eco*RI and separated in a 1% agarose gel. Comparison of the single and the double digestion patterns allowed us to localise the outmost cleavage sites of each enzyme on the 6 8-kilobase insert Additional cleavage sites were identified by comparison of the electrophoresis patterns obtained after digestion of the isolated 6.8-kilobase insert with one enzyme or various combinations of two enzymes. To correlate the restriction map with the R-loop map, we analysed R-loops formed between the γ_1 mRNA and the insert which had been digested with respective enzymes. The cleavage sites identified this way are underlined. R1, R2 and R3 in (*a*) correspond to Ex1, Ex2 and Ex3 in (*b*) respectively. *c*, Detailed restriction enzyme map around the exons Sites for *Hae*III and *Hin*fI were mapped in the five isolated pieces generated by *Taq* and *Bam* cleavage of the 6 8-kilobase insert. For each piece in turn, parallel digests were done with *Hae*III and *Hinf*, and the products were electrophoresed on 6% polyacrylamide. They were compared with similar digests of the whole insert. By noting the size of the fragments which were present only in the digests of the whole insert, and of the fragments generated from them in the *Bam*- and *Taq*-cut material, most of the sites around the *Bam* and *Taq* sites could be located. Within and between exon 1 and exon 2 all the remaining sites could also be identified, since there was only one way in which the fragments observed on single and double digests could be self-consistently ordered Two small (30–40 base pairs) *Hae*III fragments had to be postulated to make up the total length of this region One of these was confirmed, and some remaining ambiguities were resolved by labelling the 5′ ends of *Bam*-cut pieces of the 6.8-kilobase insert with [γ-^{32}P]ATP, cutting with *Hinf*, isolating the single end-labelled fragments by preparative polyacrylamide gel electrophoresis, and analysing polyacrylamide gel electrophoresis, and analysing partial digests of them by *Hae*III. Within exon 3, the 217-base pair *Hae*III fragment was identified by comparison with a *Hae*III digest of pH21-1, the cDNA clone, in which the same fragment is present The underlined cleavage sites were confirmed by Southern gel blotting analysis using the pH21-1 cDNA probe. The lengths (in base pairs) of introns and exons are based on the DNA sequencing data as well as on the size estimation of restriction fragments. Hinge coding region (exon H) was located between exon 1 and exon 2 by DNA sequencing (see text). The roman letters indicate six regions that were sequenced. Horizontal arrows indicate actual fragments used for sequencing. In, intron, Ex, exon. *d*, Correlation of domains and hinge of MOPC 21γ_1 heavy chain to four exons of Cγ_1-1 DNA. Numbers represent the amino acid positions at the domain-hinge or domain–domain boundaries Numbering starts with the first NH$_2$-terminal asparagine of the γ_1 chain

amino acid sequence of the MOPC 21 γ_1 chain was determined by Adetugbo[28]. While the presence of the sequence homology among the three C region domains is obvious, the exact domain boundaries are ambiguous. Nevertheless, examination of the internal sequence homology in the γ_1 chain and comparison of its sequence with that of a human γ_1 chain[15], for which the three dimensional structure of the Fab fragment is available[16,17] makes it possible to draw every domain-boundary within short regions that contain no more than a few amino acid residues. Thus CH1–hinge, hinge–CH2 and CH2–CH3 boundaries can be placed around residues 214–218, residues 227–228, and residues 332–335, respectively. Furthermore, the amino terminal end of the CH1 domain is around residues 115–122. The nucleotide sequences show that in all cases coding ends or begins with a residue that lies within one of these inter-domain regions deduced from structural analysis of the protein. Since it is extremely unlikely that such a correlation is a coincidence, we conclude that each of the three Cγ_1 domains and the hinge region are encoded by separate exons. Indeed one may look at it in the opposite sense and say that the exact ends of domains and the hinge region are defined by the intron–exon boundaries on the DNA.

In the coding regions the fit between the determined and the predicted nucleotide sequences is good. However, note the discrepancies in 10 codons in the regions shown in Fig. 4. Of the 10 differences, 9 are due to exchange or permutation of residues at nearby positions (for instance the Pro–Ser exchange in exon 1) and the tenth is between Ser and Thr. Thus these discrepancies are probably due to errors in determination of the amino acid sequence. Arg–Lys exchange in exon 3 was found previously[21] in the sequence of cDNA clone, pH21-1.

Are there any additional introns within the DNA segments coding for the three domains? The entire sequences of exon 1 and exon 2 segments have been determined (K. H. and H. S., unpublished), and no coding gaps were found in these regions. In exon 3, sequencing has not been completed, but the 220-base pair *Hae*III–*Hae*III fragment arising from exon 3 co-migrates with the equivalent fragment from the pH21-1 cDNA clone in a 6% acrylamide gel. It seems that there is no intron within domain-encoding segments.

Nucleotide sequences at the splice sites

The coding gaps in split genes are considered to be eliminated during processing of the primary RNA transcript by splicing of exon sequences[27–29]. The nucleotide sequences of the putative splice sites in the Cγ_1 gene are listed in Fig. 5 together with the splice site sequences of the λ_I and λ_{II} light chain genes which we previously determined[1,30]. As in all other known split genes, the exact points of coding interruption are ambiguous because of the redundancy near the opposite ends of the introns. Thus a single nucleotide G is repeated near the two ends of intron B, a dinucleotide AG near the ends of introns C, and a trinucleotide AGG near the two ends of intron D. By comparing sequences near the ends of six ovalbumin gene introns Breathnach *et al.*[31] found that it is always possible to choose cutting points so that the base sequence of an intron begins with GT and ends with AG. This rule applies to the two small introns of λ chain genes[1,30], the six introns of SV40[32] and the small introns of β-globin genes[33]. While intron C and intron D of the Cγ_1 chain gene also obey this rule, intron B does not. Because of the G repetition intron B either begins with GA and ends with CA or begins with AG and ends with AG. Another generalisation that can be made for the sequence near the ends of introns is an apparent presence of a basic sequence of several bases from which all known marginal sequences can be derived with no more than one or two base changes[31,34]. In particular we noted that all three introns of immunoglobulin λ chain genes have the sequence AGGTNAG near the 5′ end (relative to the direction of transcription)[30]. While introns C and D of the Cγ_1 gene have the same sequence at the analogous positions, intron B seems to have a quite different sequence. Sequence similarity near the 3′-end of introns is somewhat less, but YAG is shared by all introns of the λ and the γ_1 chain genes. In addition, as in most other introns, sequences rich in pyrimidines precede the basic sequence near the 3′ ends of Cγ_1 introns.

Deletion mutants

The correlation between exons and domain- or hinge-encoding DNA segments immediately drew our attention to the fact that mutant or variant immunoglobulin chains are often found in

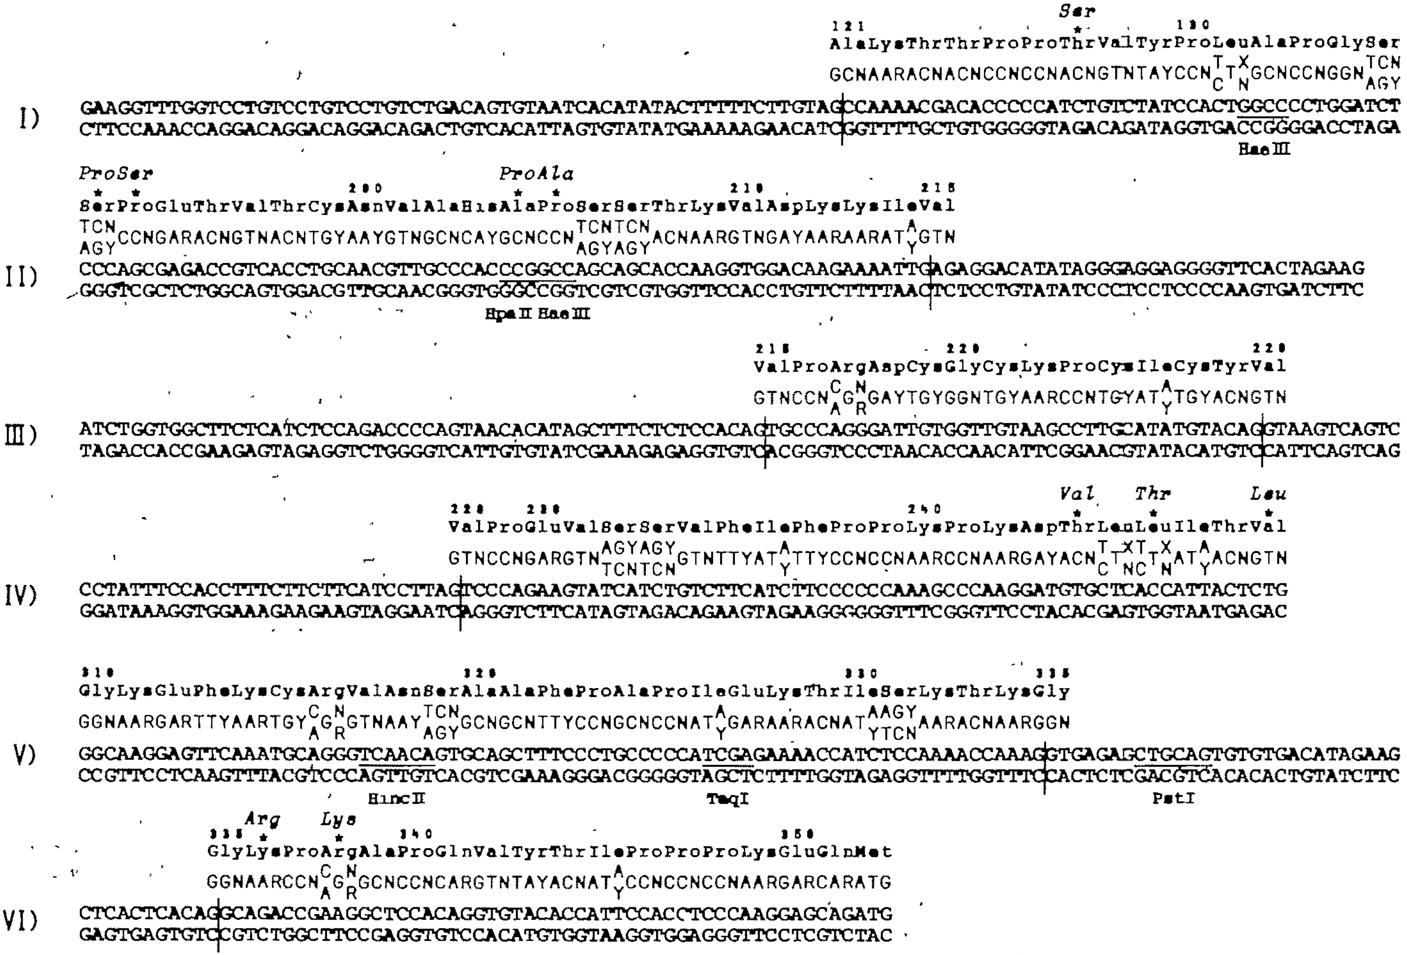

Fig. 4 Partial nucleotide sequences of clone IgCγ_1-1 Nucleotide sequences of the six regions, I, II, III, IV, V, and VI indicated in Fig. 3*c* are shown. For DNA sequencing, 2 mg of phage IgCγ_1-1 DNA was cleaved with *Kpn*I and *Xba*I and separated on a 5% polyacrylamide gel (20×40×0.5 cm). The 2.5-kilobase *Xba*I–*Kpn*I fragment (see Fig. 3*c*) containing the Cγ_1-coding sequences was eluted electrophoretically from the gel and washed by ethanol precipitation. The fragment was then cleaved with *Hin*fI, *Hae*III, *Hpa*II, *Taq*I or *Hin*cII, treated with bacterial alkaline phosphatase (Worthington), end-labelled with T_4-polynucleotide kinase (P–L Biochemicals) and [γ-^{32}P]ATP (Amersham), and sequenced by the method of Maxam and Gilbert[42] with a few modifications. Cleavage reaction at A and G was performed as follows (A. Maxam, personal communication). A mixture of end-labelled DNA and 1 μg of carrier calf thymus DNA was incubated in 23 µl of 87 mM pyridine formate *p*H 2 at 20 °C for 90 min. After lyophilisation, 20 µl of 0.5 M piperidine was added and the mixture was heated at 90 °C for 30 min in a sealed capillary. The sample was then lyophilised three times, dissolved in 10 µl of 0.1 M NaOH and 1 mM EDTA, and combined with 10 µl of urea–dye mixture. For G, C and T and C reactions, the conventional method was used except that Mg-acetate was omitted from dimethyl sulphate and hydrazine stop solutions. Reacted samples were separated in thin polyacrylamide gels (30×40×0.035 cm) at 1.5 kV as described by Sanger and Coulson[43] The figure also shows partial amino acid sequences of the γ_1 chain from myeloma MOPC 21[26] as well as the nucleotide sequences predicted from the amino acid sequence. Amino acids which do not match those predicted from our nucleotide sequence are indicated by asterisks, and the predicted amino acids are presented in italics. Vertical lines indicate possible intron–exon boundaries. Cleavage sites for some restriction endonucleases are underlined. Amino acid numbering begins with the asparagine at the NH_2-terminal end of the mature γ_1 chain from MOPC 21. N: A, G, C, or T. R: A or G. Y: C or T.

Fig. 5 Sequences around the splice sites of three immunoglobulin genes. Nucleotide sequences around the splice sites of the IgCγ_1-1 clone as well as those of Ig13λ[1] (contains an embryonic $V_{\lambda II}$ gene) and Ig303λ[30] (contains a myeloma (V+C) λ_I gene) are summarised. Intron–exon boundaries defined by the GT–AG rule[31] are indicated by vertical lines. The short 'common' sequences near the 5'- or 3'-end of introns are underlined. In case of intron B which does not follow the GT–AG rule, the boundaries indicated are based on the assumption that the intron ends with AG (see text). Nucleotides repeated near the opposite ends of an intron are marked with asterisks. CH1, CH2 and CH3 designate the three constant region domains of the γ_1 heavy chain. L, V, J, and C designate the hydrophobic leader, variable, joint, and constant region of the λ_I or λ_{II} light chain

which an entire domain or the hinge region is deleted. Franklin and Frangioni reported several examples of so-called human heavy chain disease proteins with such characteristics[35]. In the present context, one mouse γ_1 chain mutant isolated from cultured MOPC 21 myeloma cells is of particular interest[36]. This mutant, called IF2, lacks the CH1 domain extending from residue 121 to residue 214. The deleted amino acids are exactly those that are encoded by exon 1 (Fig. 4). The so-called C_κ fragment found in myeloma MPC 11 may be another example[37]. The sequence of the amino terminal region of the C_κ fragment that had been synthesised in a cell-free translation system under the direction of purified C_κ fragment mRNA has been determined [38,39]. The sequence suggests that the C_κ fragment is synthesised in the cells as a precursor carrying a hydrophobic leader peptide at the amino terminus. In the precursor a 17-residue long leader is directly attached to the C_κ region peptide. Our previous results showed that both the leader and the V regions are encoded in separate exons in mouse λ chain genes[1,30]. If the same applies to κ chain genes, the C_κ fragment precursor may be considered as a deletion variant in which the entire peptide encoded in the V-coding exon is deleted.

Assuming that the splicing enzyme can potentially bridge two non-adjacent exons, then all deletions which begin in one intron and end in another could generate a single mutant protein in which the entire polypeptides encoded in exons between the two introns are deleted. Alternatively, a mutation at or near a splice site, whether it is a deletion or a base change, could perturb the splicing pattern such that the entire sequence in one exon is skipped in the mRNA. For instance, certain mutations near the intron B–exon H boundary may block splicing of exon 1 with exon H and in turn may promote its splicing with exon 2. Cloning and analysis of the relevant DNA fragments from mutant cells will test these models directly.

Evolution of immunoglobulin genes and origin of introns

How splicing arose in evolution is unknown. Crick has suggested that splicing was originally a protection mechanism, evolved by the host organism to reduce the damage being inflicted by the insertion of nonsense sequences in the middle of the gene (F. Crick, personal communication). In this hypothesis, the introns are viewed as DNA elements that were once inserted more or less randomly within a pre-existing gene. The placement of introns in ovalbumin and β-globin genes indeed seems to be random. However, the presence of introns at the regularly spaced boundaries of domain-coding DNA segments and at the boundaries of the domain- and hinge-encoding DNA segment is in apparent contrast to such a 'random' insertion of DNA elements. To explain the regularity observed in the location of the introns we propose the following scheme as a possible and likely process of the evolution of an immunoglobulin heavy chain gene. It is likely that when the putative primordial gene duplicated, the unit of duplication was substantially larger than the unit of translation. As DNA duplication is likely to involve some form of illegitimate recombination which makes use of accidental short sequence homology, there is no *a priori* reason why a domain coding DNA segment would be duplicated immediately adjacent to itself. Most probably, the duplicated DNA would contain a spacer between the two domain-encoding DNA segments. One obvious way to fuse the DNA segments is to delete the spacer. But, for exactly the same reason as given above for the duplication step, such a deletion is probably a rare event. Instead, the organism might very well have resorted to a pre-existing splicing mechanism that might have developed under an evolutionary pressure such as that suggested by Crick.

How did the necessary splice sites arise at or near the ends of the domain-encoding DNA segments? One possibility is the primordial domain gene was itself an intact exon bound by splice sites. Alternatively, splice sites might have been created *de novo* by drift at the proper regions after duplication. In most cases, there seems to be a basic sequence of four to six bases to which sequences near the margins of introns are related in varying degrees. While it may not be difficult to imagine that a proper sequence of this length is generated rather frequently by drift, the specificity provided by these sequences cannot be sufficient. The same sequence is also found within exons[34]. The obvious possibility is that combination of some higher order structure and the sequence information determine the specificity.

To generate the four-domain heavy chain gene the process outlined above is imagined to have been repeated. An additional aspect of the evolution of heavy chain genes is the generation of the hinge-coding exon. While it is possible to imagine that this exon arose from part of the ancestral intron between exon 1 and exon 2, there are two more interesting possibilities. One is that the hinge evolved by reduction of an extra C region domain corresponding to the CH2 domain which is found in place of hinge in μ and ε chains[44]. The other is the DNA segment containing the hinge-coding sequence with or without ready-made splice sites at its margins was inserted into the ancestral intron between the exon 1 and exon 2.

Whichever variation of the model described above is more likely to be correct, it suggests that the splicing mechanism, with or without recombination at the DNA level, enables an organism to create a new gene by assembling DNA pieces each coding for a polypeptide chain of some functional use[1]. If such a gene creation process indeed took place in evolution, some of the present day introns should be regarded as spacers between assembled exons and not as insertion sequences *per se*. As suggested by the hinge-coding exon and the hydrophobic leader-coding exon[1,30], the correlation between a clearly defined protein domain and an exon is not a necessary element of the proposed gene creation process. A DNA segment that codes for a protein of some function and flanked by splice sites, whether they arose from the margins of insertion elements or by mutational drift, can combine with another such segment coding for a protein of a similar or an entirely different function. The function could be for binding with a specific ligand, for providing disulphide bridges or even for simply providing a peptide that can stabilise the overall structure of the newly created protein.

Photon decay in curved space-time

RECENT astrophysical observations[1,2] have raised doubts as to whether the large redshifts of distant galaxies (the Hubble redshift) are due entirely to cosmological expansion. The strongest argument[3] in favour of cosmological expansion is that there is no known hypothesis consistent with the laws of physics (other than the Doppler shift hypothesis) that can explain the observed redshifts. An alternative explanation—a gradual energy loss of photons due to their interaction with curved space-time—is considered here. The basic premise is that because photons have a finite spread they are subject to tidal stresses and that this provides a mechanism for the transfer of momentum from the photon to the mass producing curved space-time. Any transfer of momentum without an equivalent transfer of energy will destroy the concept of the photon as a single elementary particle. It is therefore postulated that the interaction of the photon with curved space-time causes it to lose energy in the form of very low energy secondary photons. As well as providing an explanation for the Hubble redshift this hypothesis can also explain the solar limb effect, that is, the increasing redshift of solar spectral lines as the viewpoint approaches the limb of the Sun.

Most texts that consider the passage of light in curved space-time equate the trajectory of a photon to that of a light ray, thereby neglecting any lateral spread the photon may have. If we exclude the possibility of infinite energy density then in some sense not yet defined a photon must have a finite non-zero cross-sectional area. A better model for the photon is a bundle of light rays. The effect of the tidal stresses on this bundle is shown by their relative deviations from a central reference geodesic. An appropriate coordinate system is an orthonormal Riemann coordinate system that is parallel transported along this central geodesic. Furthermore, every point along the central geodesic is uniquely labelled by the value of an affine parameter τ. As the deviations that are linear in τ given only reversible focusing (or defocusing) effects they will be ignored and we shall consider only the irreversible deviations that are quadratic in τ. These are given by the familiar equation for geodesic deviation.

The propagation of light in curved space-time is identical to propagation in a medium with a heterogeneous refractive index[4]. As the solution of Maxwell's equations is much easier for the latter case this approach is adopted here. The refractive index that gives the same geometric behaviour of light rays as the deviation of geodesics is radially symmetric about the axis of propagation and has the form

$$n = (1 - \varepsilon^2((x^2)^2 + (x^3)^2))^{1/2} \tag{1}$$

where ε is a small constant and the central geodesic is along the x^1 axis. Then to order ε propagating wave solutions can be found with a gaussian amplitude distribution in the radial direction and requiring the dispersion relationship

$$\omega_0^2 = c^2 k_0^2 + 2\varepsilon\omega_0 c \tag{2}$$

where ω_0 is the circular frequency and k_0 is the wavenumber. This gives a group velocity of $v = (1 - \varepsilon/k_0)c$, where c is the velocity of light along the reference geodesic.

Equation (2) can be interpreted as giving the wave packet an effective mass of $m = (2\varepsilon/k_0)^{1/2}(E_0/c^2)$ where $E_0 = \hbar\omega_0$ is the energy of the wave packet. The basic hypothesis here is that the same result applies to a photon in curved space-time and that this effective rest mass is just the energy of two secondary photons that are being emitted. Two secondaries are required to preserve spin. Each secondary has a wavenumber $k = (\frac{1}{2}\varepsilon k_0)^{1/2}$.

0028-0836/79/0277—0633$01 00

The Heisenberg uncertainty principle ($\Delta k_0 \Delta x \simeq 1$) can be applied to one of the secondary photons to estimate the rate of production of these secondaries and hence the rate of energy loss by the primary photon. Then with $\Delta k_0 = k = (\frac{1}{2}\varepsilon k_0)^{1/2}$ the distance between secondary emissions is given by $\Delta x = (\frac{1}{2}\varepsilon k_0)^{-1/2}$. Then the energy loss rate is equal to $2\hbar\, \Delta k_0/\Delta x$, which is

$$\frac{\mathrm{d}E_0}{\mathrm{d}x^1} = -\varepsilon E_0 \tag{3}$$

Finally, it is possible to find the correspondence between the parameter ε in the refractive index equation and the equation of geodesic deviation. For a light ray travelling along the x-axis in an inhomogeneous medium there is the general result that $\frac{\mathrm{d}^2 y}{\mathrm{d}x^2} = -\frac{1}{n}\frac{\mathrm{d}n}{\mathrm{d}y}$. Combining this with equation (1) and the equation for geodesic deviation[5] we find

$$\varepsilon^2 = -(R^2_{\beta 2\delta} + R^3_{\beta 3\delta})\frac{\mathrm{d}x^\beta}{\mathrm{d}\tau}\frac{\mathrm{d}x^\delta}{\mathrm{d}\tau} \tag{4}$$

with $\beta, \delta = 0, 1, 2, 3$ where $R^\alpha_{\beta\gamma\delta}$ is the Riemann–Christoffel curvature tensor, and the distance is now measured by the more general affine parameter τ.

Evaluation of ε is readily done in the Post-newtonian approximation to general relativity. In this approximation the metric tensor is diagonal with elements

$$g_{00} = -(1 + 2\phi + 2\phi^2)$$
$$g_{ii} = 1 - 2\phi \ (i = 1, 2, 3)$$

where ϕ is the newtonian gravitational potential. The result is

$$\varepsilon^2 = 2\nabla^2\phi - 2\phi\frac{\partial^2\phi}{(\partial x^1)^2} + 2\sum_{i=1}^{3}\left(\frac{\partial\phi}{\partial x^1}\right)^2 \tag{5}$$

with the coordinate x^1 being used as the affine parameter. This gives ε the dimensions of inverse length. For a system of uniform density ρ we can use Poisson's equation to get from equations (3) and (5)

$$\frac{1}{E_0}\frac{\mathrm{d}E_0}{\mathrm{d}x} = -\left(\frac{8\pi G\rho}{c^2}\right)^{1/2} \tag{6}$$

where the replacement $x^1 \to x$ has been made. Near a single mass like the sun we have $\phi = -\frac{GM}{c^2 r}$ giving

$$\frac{1}{E}\frac{\mathrm{d}E}{\mathrm{d}x} = -\frac{2GM}{c^2 r^2}\left(1 - \frac{3x^2}{2r^2}\right)^{1/2} \tag{7}$$

Note that equation (6) comes from the first term in equation (5) which is linear in ϕ whereas equation (7) comes from the other terms that are quadratic in ϕ.

As the energy loss rate predicted by equation (6) is proportional to the photon energy the observed frequency shift cannot be distinguished from a doppler shift. It is of interest to determine whether equation (6) with the density of the intergalactic medium can account for the Hubble redshift in a static universe. For a density of n hydrogen atoms m^{-3} the predicted redshift is

$$z = (\lambda - \lambda_0)/\lambda_0 = \mathrm{e}^{-Hx} - 1 \simeq Hx \tag{8}$$

where $H = 5.59 \times 10^{-27} n^{1/2} \mathrm{m}^{-1}$. In more familiar units this is $51.7 n^{1/2}$ km s^{-1} (Mpc)$^{-1}$. Comparison with the conventional value[6] of 55 km s^{-1} (Mpc)$^{-1}$ shows that this theory can explain the Hubble redshift if $n \simeq 1\ \mathrm{m}^{-3}$.

The most direct measurement of the density of the intergalactic plasma has been made by Field and Perrenod[7] who find that the background X-ray observations come from a fully ionised plasma at a temperature of 10^8–10^9 K and a density of $n = 1.6C^{-1/2}\ \mathrm{m}^{-3}$, where $C = \langle n^2\rangle/\langle n\rangle^2$ is a clumping factor. However, this result was obtained with an expanding universe, where the density at past epochs was greater than this value. For a static universe of constant density (but still allowing an energy-loss with distance) a reanalysis of the same data gives $T = 1.3 \times 10^9$ K and $n = 2.4C^{-4/3}\ \mathrm{m}^{-3}$, which gives a Hubble value of $80C^{-2/3}$ km s^{-1} (Mpc)$^{-1}$. Unfortunately there is no direct evidence as to the value of the clumping factor C that would give a direct estimate of the Hubble constant. For this density the conventional value of 55 km s^{-1} (Mpc)$^{-1}$ requires that $C = 1.8$ and that there is an upper limit to the Hubble constant of 80 km s^{-1} (Mpc)$^{-1}$.

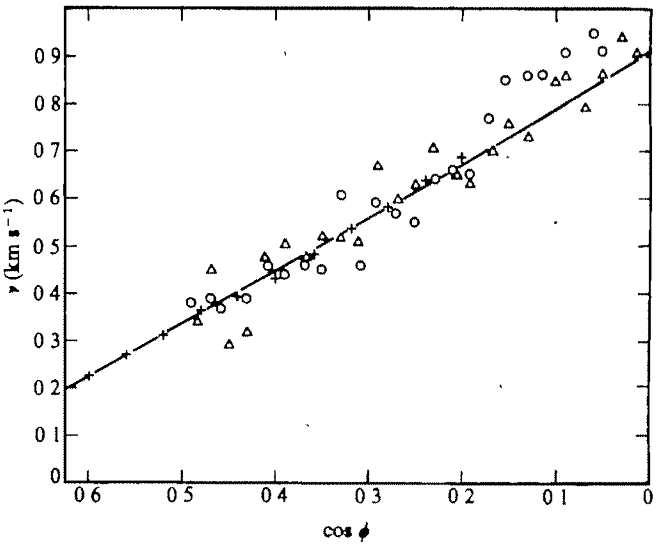

Fig. 1 The predicted (solid line) and observed solar limb effect. The redshift, expressed as a velocity is plotted against cos (ϕ) where ϕ is the angle between the line of sight and the solar radius. The solid line is the predicted shift from equation 9. The experimental results are: + Plaskett[10]; △, Adam[8]; and ○, Higgs[9]. All experimental results have been corrected for an apparent radial velocity of 0.39 km s^{-1} (ref. 11).

As this is only a plausibility argument several important corrections have been omitted. The first is that the cosmological curvature has been ignored. This could increase H by ~15%. The second is that relativistic corrections to the Gaunt factor (used in calculating the X-ray emission intensity) have been omitted. Finally the assumption of an iso-thermal intergalactic plasma has been made in spite of possible density variations. Nevertheless, I suggest that the Hubble redshift could be the observed result of a photon–gravitational interaction.

Careful measurements of the Fraunhofer lines wavelengths show a small but systematic redshift across the solar disk reaching a maximum on the limb. The effect can test the validity of the second order terms in the energy loss as given by equation 7. If ϕ is the angle between the line of sight and the solar radius, the expected redshift (expressed as an equivalent doppler velocity) is given by

$$v(\phi) = \frac{2GM}{Rc\sin(\phi)}\int_{\phi_0}^{\phi}\left(1 - \tfrac{3}{2}\cos^2(\phi)\right)^{1/2}\mathrm{d}\phi \tag{9}$$

where $\cos^2(\phi_0) = 2/3$. The effect is zero for $\phi < \phi_0$ and then increases monotonically to a value of 0.911 km s^{-1} at the limb. Equation (9) is plotted in Fig. 1 together with the observations of Adam[8], Higgs[9] and Plaskett[10]. All the observations have been corrected for a radial velocity of 0.39 km s^{-1} (as determined by Plaskett[11]). There is excellent agreement with the r.m.s. residuals from Plaskett's data being 0.012 km s^{-1} and for each of the others 0.05 km s^{-1}.

Integrated over the whole disk the average equivalent redshift velocity is 0.191 km s^{-1} in addition to the normal Einstein gravitational value of 0.634 km s^{-1}. Limb darkening alters this to 0.153 km s^{-1} (from Allen[12], with $u_2 = 0.84$, $v_2 = -0.20$). For other stars with similar limb darkening the equivalent redshift velocity is 0.787 m/r km s^{-1} where m and r are measured in solar units. This value is not inconsistent with observations of white dwarfs and may help to resolve some disagreements between gravitational radii and those estimated from model atmospheres.

This theory clearly predicts that if the line of sight to a radio source or a spacecraft passes near the Sun there will be a substantial redshift in the observed frequency. Observations[13] of Taurus A at 1,420 Mhz with an impact parameter of $5R_{\odot}$ suggest a possible shift of ~120 Hz, whereas observations[14] of W28 at 1,612 Mhz showed no shift. The most precise results[15,16] are observations of the Pioneer-6 spacecraft at 2,292 MHz. A consistent and unexplained redshift was observed as the spacecraft went behind the Sun, being 120 Hz at $4R_{\odot}$. The anomaly is that this theory predicts a shifts of 3,500 Hz in this case and shifts of ~2,000 Hz for the radio sources.

The explanation of the discrepancy possibly lies in an inhibition effect due to the presence of the solar corona. Efficient emission of radiation requires phase coherence of the emitting mechanism over a distance of the same size as the emitted wavelength. In this case the distance required is of order $k^{-1} = (\frac{1}{2}\varepsilon k_0)^{-1/2}$. It is convenient to think of the secondary radiation being produced by an interaction between the primary photon and a gravitational wave. However, the presence of a plasma, in this case the solar corona, alters the velocity of the photon but not that of the gravitational wave. If the primary photon has a frequency low enough to suffer a relative phase shift of π radians over the emission distance the rate of secondary emission will be decreased subtantially. For a plasma this critical frequency, ω_c, is given by $\omega_c = (2\omega_p^4/\varepsilon c)^{1/3}$ where ω_p is the circular plasma frequency. Typical values for the solar corona are $\omega_o = 1.0\times10^{11}$ Hz at 3 R_0 and $2.3\times10_{10}$ Hz at 10 R_0, showing that the critical frequency is well above the observational frequencies; thus strong inhibition of the interaction seems likely.

This is not the first proposal that relates the redshift to the effect of mass or gravitational fields on photons. Furth[17] derived an expression for frequency shift proportional to curvature by analogy with an electron in a circular orbit. However, he considered curvature in three spatial dimensions only and suggested that the energy loss went into gravitational waves. Stephenson[18] proposed that there would be a redshift due to absorption or shielding of gravitational flux. Gillieson[19] used a mechanical model for the photon to explain the observed limb effect. He arrived at a redshift proportional to M/r. A similar dependence was predicted by Proisy[20] whereas Sadeh, Knowles and Au[13] prefer M/r^2. Mo and Pappas[21] have treated the propagation of a classical electromagnetic wave in a Schwarzchild field which is treated as an equivalent medium. They find amplitude variations proportional to $\exp(M/r)$. However, none of these authors gives theory as widely applicable as the one presented here, nor do they consider the production of low energy photons as a result of the energy loss.

I argued previously[22] that the angular momentum and linear momentum cannot both remain invariant in curved space-time. The method used a classical description of the momenta as volume integrals of the Poynting vector and treated curved space-time as an inhomogeneous refractive medium. Although the predicted energy loss for a photon passing near the Sun is similar to equation (7) the over-simplified treatment of curved space-time makes the earlier results inaccurate.

I thank Professor B. Y. Mills and Dr A. J. Turtle for helpful criticism.

Observations of solar oscillations with periods of 160 minutes

OSCILLATIONS of the Sun with a period near 160 min have been reported by Severny *et al.*[1] and further described by Kotov *et al.*[2]. The presence of such oscillations would lead to a significant increase in our knowledge of solar physics. The reported amplitude is of the order of 1 ms^{-1} which is near the limit of observing technology. Observations described here at the Stanford Solar Observatory from 1975 to the present seem to support the reports from the Crimean Astrophysical Observatory[1,2].

At Stanford the relative velocity between a central circular area of radius $0.5R_{\odot}$ on the solar disk and most of the remaining area of the solar disk is measured. An optical scheme similar to that described in refs 1 and 2 is used and is described in detail by Dittmer[3].

Light from the central portion of the solar disk is passed through a right circular polariser and light from the outer portion through a left circular polariser. The solar line Fe I λ5124 Å is observed and a Babcock magnetograph is used to measure the wavelength separation between left and right circularly polarised light, that is the difference between the velocity of the central part of the solar disk and the outer portion.

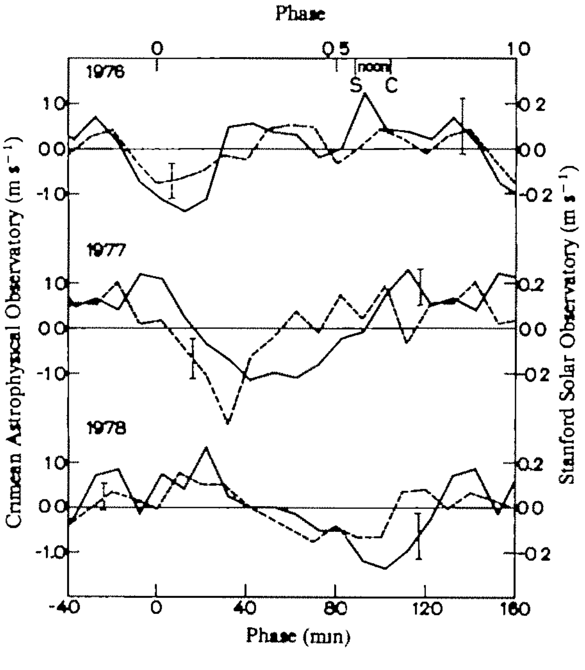

Fig. 1 Superposed epoch analyses with a period of 160 min for the observations during individual years at the Stanford Solar Observatory (solid line) and at the Crimean Astrophysical Observatory (dashed line) of the difference in velocity between the central portion of the solar disk and the outer portion.

Table 1 Summary of Stanford and Crimean observations

Year	Observatory	Dates	Days	Hours	Harmonic amplitude	Phase (min)
1974	Crimea	4 August– 9 October	14	76	1.43	−22
1975	Crimea	28 June– 14 October	28	157	0.89	−14
1976	Crimea	26 April– 15 October	32	161	0.36	8
	Stanford	1 July– 15 September	38	178	0.14	10
1977	Crimea	11 March– 24 October	59	280	0.78	32
	Stanford	6 April– 30 July	43	180	0.21	57
1978	Crimea	22 April– 20 August	60	361	0.47	82
	Stanford	7 June– 21 August	25	130	0.17	94

The fact that the period of 160 min is exactly one-ninth of a day requires that extreme caution be used in asserting that the observed oscillations are solar rather than terrestrial. Our observations considered as a continuous dataset lasting several months (or years) have considerable power at a period of 24 h because we do not observe at night and because there are drifts in the zero level through the day. At Stanford drifts in the guiding system are found to cause typically a 20 ms^{-1} drift in the signal baseline through a day. These drifts are removed by a parabolic fit. We describe here a superposed epoch analysis of the observations using a period of 160 min. This is equivalent to applying a filter that admits power corresponding to this period so that even if we have only noise input we will expect to receive a signal in the superposed epoch analysis. The comparison of observations between Stanford and the Crimea then rests largely on the relative phase of the observed oscillations at the two sites. If we both are observing a solar phenomenon we should expect to have the same phase within observational error, while if we are observing terrestrial phenomena or simply noise we should not expect phase agreement. During each of the years 1976, 1977 and 1978 the phase at the two observatories has been nearly the same, which supports the solar origin of the oscillations first reported at the Crimean Astrophysical Observatory[1,2]. Table 1 gives the observing schedule during each year and the observed phase.

Figure 1 shows a superposed epoch analysis with period 160 min of the observations during each year at the Stanford Solar Observatory (solid line) and at the Crimean Astrophysical Observatory (dashed line). Negative velocity represents expansion of the Sun (motion of the central part of the disk towards the observer, note that this is the opposite of the convention used in previous Crimean publications on this subject) and the error bars are twice the standard error of the means. The zero phase in Fig. 1 is at 0 h UT.

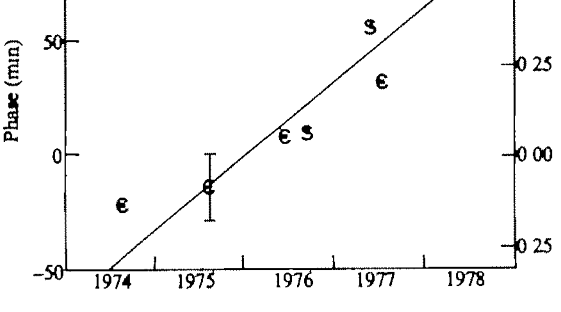

Fig. 2 Time of maximum expansion in minutes from 0 h UT for Stanford Observations (S) and Crimean Observations (C). The phase is computed from a harmonic analysis. The error bar shows the typical uncertainty in phase.

Figure 1 shows that in each of the three years the phase at the two observatories is nearly the same. Figure 1 also shows changes in amplitude from year to year that are about the same for both observatories. On a time scale of months there also seems to be similar changes in amplitude at the two observatories, but due to the small amount of simultaneous observations (due to weather and observing schedules) the significance and origin of these variations is still uncertain.

We compute based on instrumental parameters (the size of the portion of the solar disk that is compared with the central portion of the disk) that the lowest mode of solar oscillation would be observed at the Crimea with twice the amplitude of the Stanford signal. The remaining factor of about two shown in Fig. 1 between the amplitude of oscillations observed at the Crimea and at Stanford is not understood.

Figure 1 shows an apparent drift in phase from one year to the next. A drift in phase computed with a fixed period is the same as an error in the period. This suggests that 160.0 min may not be exactly the correct period. Figure 2 shows the phase for all the yearly sets of observations available from both observatories. The fact that the points from both observatories tend to fall nearly on a straight line suggests that both sets of observations show solar motions. From the slope of a best fit line we compute a drift in phase of about 33 min per yr corresponding to a period of about 160.01 min.

An unknown terrestrial effect related to the time of local noon could yield an agreement in phase between the two observatories if they were separated in longitude by an integral number of 360°/9 intervals, as we are dealing with a period of one-ninth of a day. In fact the two observatories are separated by 3.9 such intervals, such that Stanford would have a phase 16 min earlier than the Crimea. In the three years in which we have observed, Stanford tends to have a phase later than the Crimea.

The apparent agreement in phase between the two observatories as well as the fact that the period seems to differ slightly from exactly one-ninth of a day tends to support the interpretation that we are observing solar oscillations. The dependence of the amplitude of the oscillations on the phase of solar rotation recently observed in the Crimea[4] is also encouraging in this respect. Subject to the results of further years observations our present working hypothesis is that the oscillations are solar and that we can proceed towards further study of the modes involved and of the implications for our understanding of the Sun's interior.

Photoelectrocatalytic reduction of carbon dioxide in aqueous suspensions of semiconductor powders

We report here the photoelectrocatalytic reduction of carbon dioxide to form organic compounds such as formic acid, formaldeyde, methyl alcohol and methane, in the presence of photosensitive semiconductor powders suspended in water as catalysts. Photocatalytic reaction kinetics were elucidated by reference to the theory of charge transfer at photoexcited semiconductors.

Heterogeneous photocatalytic reactions have recently been used to synthesise chemical compounds, thereby converting solar energy to chemical energy[1–4]. Schrauzer and Guth have reported the photocatalytic reduction of nitrogen on a catalyst of wet TiO_2 powder. Oxygen and hydrogen were formed through the decomposition of water, and ammonia and/or hydrazine were also obtained through the photo-assisted synthesis of nitrogen and water on the TiO_2 catalyst[3]. Semiconductor photoelectrodes have been much investigated, with emphasis on electrochemical photocells converting solar energy to chemical and/or electrical energy[5,6]. Photogenerated carriers (electrons and holes) in the space charge layer of a semiconductor electrode can transfer to the reactants in an electrolyte solution, and cause the photoassisted decomposition or synthesis of chemical compounds[7,8]. Semiconductor catalysts may be assumed to undergo charge transfer across a solid–liquid junction similar to that in semiconductor electrodes; that is, charge transfer between semiconductor and redox reagents in solution would take the form of a conduction band and a valence band. Hemminger *et al.* have reported that methane was formed through the photosynthetic reaction of gas phase water and carbon dioxide molecules adsorbed onto strontium titanate surfaces in contact with platinum foil[9]. Recently Halmann has reported that carbon dioxide in an aqueous solution was reduced to formic acid at the p-type GaP photocathode in the electrochemical photocell with a fairly high conversion efficiency[10].

In this study we attempted the photocatalytic reduction of carbon dioxide on various semiconductor photo-catalysts such as WO_3, TiO_2, ZnO, CdS, GaP, and SiC (99.5–99.9999% purity). In each case, semiconductor powder (200–400 mesh) 1.0–2.0 g was suspended in the 100 ml of purified water in a glass cell. Highly purified carbon dioxide gas was bubbled at 3 litres per min through a water-suspended catalyst shaken by a magnetic stirrer. The suspensions were illuminated, through a quartz window in the glass cell, by a 500 W Xe lamp or a 500 W high pressure mercury arc lamp. Illumination wavelengths were selected with cutoff filters. Products of the photocatalytic reactions were analysed by gas chromatography (Hitachi 163) using polyethyleneglycol (PEG) 200 and molecular sieve as column.

Table 1 Summary of yields of reduced products of carbon dioxide on various semiconductor catalysts

Catalysts (1.0 g/100 ml water)	Illumination period (h)	Yields of products HCHO ($\times 10^{-3}$ M)	CH$_3$OH ($\times 10^{-4}$ M)
TiO_2	7.0	1.1	2.3
TiO_2	14.0	1 8	7.8
TiO_2	30.0	1.8	14 6
TiO_2^*	7.0	0.0	0.0
ZnO	7.0	1.2	3.5
CdS	7.0	2.0	11.7
GaP	7.0	1.0	11.0
SiC	7.0	1.0	53.5
WO_3	7.0	0.0	0.0
Electrodes (−1.5 V vs SCE)	**Amount of charges (C)**	**Yields of products HCHO ($\times 10^{-3}$ M)**	**CH$_3$OH ($\times 10^{-4}$ M)**
TiO_2†	108	1.7	11.7
TiO_2‡	180	2.8	56 7
p-GaP§	240	3.6	73.0

* TiO_2 suspension was illuminated with light of wavelengths longer than 500 nm.

† TiO_2 electrode in 50 mM H_2SO_4 aqueous solution was not illuminated.

‡ TiO_2 electrode in 500 mM H_2SO_4 aqueous solution was not illuminated.

§ GaP electrode in 500 mM H_2SO_4 aqueous solution was illuminated with light of wavelengths shorter than 500 nm.

Formic acid, formaldehyde, and methyl alcohol were produced through the photocatalytic reduction of carbon dioxide in aqueous suspensions of semiconductors such as TiO_2, ZnO, CdS, GaP and SiC, when the suspensions were illuminated with light which was absorbable for the catalyst. A trace of methane was also detected in the gaseous products, which were trapped with liquid nitrogen refrigerant. Results of quantitative analysis of yields of reduced compounds from photocatalytic reduction of carbon dioxide in aqueous suspensions are given in Table 1. When the experiments were carried out in the dark or under illumination with a light not absorbed by semiconductor catalysts, no reduced products of carbon dioxide were detected with any of the semiconductor catalysts tested; as an example the results with TiO_2 are shown in Table 1.

The photocatalytic reactions are considered to follow the schemes.

$$\text{catalyst} + h\nu \longrightarrow \text{catalyst}^*(e^-_{\text{cond}} + p^+_{\text{val}})$$

for an oxidation

$$H_2O + 2p^+_{\text{val}} \longrightarrow 1/2O_2 + 2H^+$$

for reductions

$$CO_2(aq) + 2H^+ + 2e^-_{\text{cond}} \longrightarrow HCOOH$$
$$HCOOH + 2H^+ + 2e^-_{\text{cond}} \longrightarrow HCHO + H_2O$$
$$HCHO + 2H^+ + 2e^-_{\text{cond}} \longrightarrow CH_3OH$$
$$CH_3OH + 2H^+ + 2e^-_{\text{cond}} \longrightarrow CH_4 + H_2O$$

where e^-_{cond} and p^+_{val} denote an electron in the conduction band and a positive hole in the valence band, respectively.

Reduced compounds such as formaldehyde and methyl alcohol were best produced on SiC semiconductor catalyst after

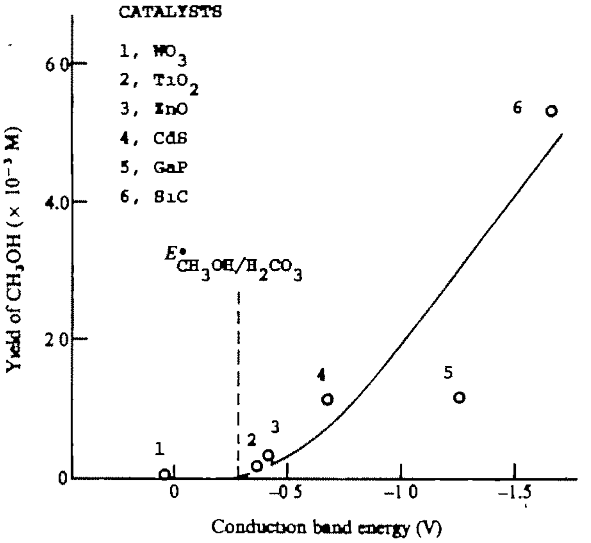

Fig. 1 Correlation between the yield of CH_3OH and the conduction bands of semiconductor catalysts. Dashed line denotes the standard redox potential of a CH_3OH/H_2CO_3 couple. Potentials are expressed against the normal hydrogen electrode (NHE).

illumination for 7 h, as shown in Table 1. Figure 1 shows the yields of methyl alcohol by photocatalytic reduction of carbon dioxide as a function of the energy levels of the conduction band of the semiconductor catalysts. The yields of methyl alcohol increase as the conduction band becomes more negative with respect to the redox potential of H_2CO_3/CH_3OH, whereas methyl alcohol was not produced in the presence of WO_3 catalyst which has a conduction band more positive than the redox potential of H_2CO_3/CH_3OH.

In experiments with semiconductor electrodes, carbon dioxide was reduced electrolytically to formic acid, formaldehyde, methyl alcohol and methane at the unilluminated TiO_2 electrode or at the illuminated p-type GaP electrode when both semiconductor electrodes were polarised at a potential of −1.5 V against a saturated calomel electrode for 2 h (Table 1). Thus electrons in the conduction band of semiconductor electrodes are able to reduce carbon dioxide in an aqueous solution.

It has been suggested that at semiconductor electrodes, the charge transfer rates between photogenerated carriers in semiconductors and the solution species depend on the correlation of energy levels between the semiconductor and the redox agents in the solution[11-13]. That is, the solution species of redox potential the more positive with respect to the conduction band level is better reduced at semiconductors. This hypothesis is illustrated in Fig. 2 which shows the energy correlation at the semiconductor–solution junction. When estimating charge transfer it is assumed that for semiconductor catalysts, as for semiconductor electrodes, photo-excited electrons in the more negative conduction band have the greater ability to reduce carbon dioxide in the solution.

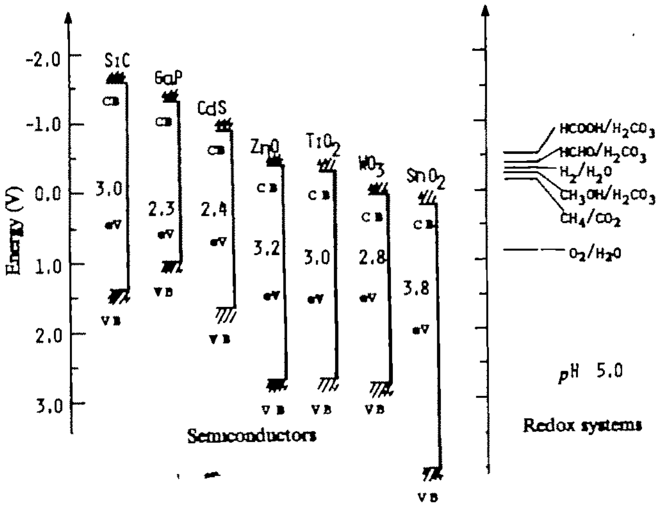

Fig. 2 A schematic illustration of the energy correlation between semiconductor catalysts and redox couples in water. CB and VB denote a conduction band and a valence band, respectively.

Thus the photocatalytic reaction on a semiconductor catalyst appears to take place through the action of the photogenerated carriers (electrons and holes) acting as components of a local cell—reduction by electrons occurring in a conduction band and oxidation by holes in a valence band. The estimated quantum yields of production for photocatalytic reduction of carbon dioxide were ~5.0×10^{-4} for HCHO and 1.9×10^{-4} for CH_3OH with a TiO_2 catalyst, and 5.0×10^{-4} for HCHO and 4.5×10^{-3} for CH_3OH with SiC as catalyst, measured against the absorbable incident photons. We are now investigating the detailed dynamics of the photocatalytic reaction on the semiconductor catalysts.

Highly efficient quantum conversion at chlorophyll *a*–lecithin mixed monolayer coated electrodes

THE design of solar conversion systems based on the photosynthetic primary reactions has attracted much attention recently. For instance, photoelectrolysis at a chlorophyll (Chl) *a*–water aggregate coated platinum electrode as a photocathode has been studied by Fong *et al.*[1-3], and simulation of the photoinduced electron transfer across the thylakoid membrane as well as of the biological ordered structure in a chloroplast has been attempted by Tien *et al.*[4,5] using a Chl *a*–containing bilayer lipid membrane (BLM). We have already attempted to combine these different approaches[6] by using a Chl *a* monolayer coated SnO_2 transparent electrode as a photoanode, and a maximum photocurrent quantum efficiency of 12–16% was attained with Chl *a*–stearic acid mixed monolayer systems. In that case, however, a decrease of the quantum efficiency was observed at Chl *a*–stearic acid molar ratios <1.0; this might be due to the formation of pheophytin *a* and/or to a possible heterogeneity of the mixed monolayers. We describe here how we have overcome such problems by using a phospholipid instead of the fatty acid as a

0028-0836/79/0277—0638$01 00

diluent for a Chl *a* monolayer. The hydrophobic interactions between Chl *a* and phospholipids have been well investigated both *in vivo* and *in vitro*, and the physical stability and photochemical activity of Chl *a*–synthetic lipid mixed layers were also confirmed in the BLM study[7].

Chl *a* was prepared from spinach as previously reported[6]. Synthetic L-α-dipalmitoyl lecithin (DPL, Sigma) was used as a phospholipid without further purification. An SnO_2 optically transparent electrode (OTE)[6] was used as a substrate of the monolayer deposition. The mixed monolayers of Chl *a* and DPL were prepared by spreading 2×10^{-4} M benzene solutions of Chl *a* and DPL in various molar ratios onto 10^{-3} M phosphate buffer solution (pH 7.5–8.0) in a Langmuir trough. A single layer of the mixed monolayer formed on the aqueous surface was deposited onto the SnO_2 OTE under the constant surface pressure of 20 dyn cm^{-1}. The electrochemical measurement setup was as reported previously[6]. The electrolyte solution used consisted of 0.1 M Na_2SO_4, 0.025 M phosphate buffer (pH 6.9), and 0.05 M hydroquinone as a reducing agent, and was flushed with nitrogen throughout the experiments. Monochromatic light from a 500-W Xe-arc lamp irradiated the monolayer coated SnO_2 OTE and the photocurrent was measured by a Keithley picoammeter (Model 417) in a potentiostatic condition of +0.1 V *versus* saturated calomel electrode (SCE).

The surface pressure–area (*F*–*A*) characteristic of Chl *a*–DPL mixed monolayer is compared in Fig. 1 with that of pure Chl *a*[6]. The stability of the mixed monolayer, even at pressures higher than 24 dyn cm^{-1} (the collapse pressure of Chl *a* monolayer), implies that the present Chl *a*–DPL mixed monolayer could form a homogeneous two-dimensional solution. This homogeneity can be also supported by the observed change in the absorption property of the mixed monolayer following the dilution of Chl *a* content. On decreasing the molar ratio of Chl *a*–DPL from 1:0 to 1:99, the peak position of the red absorption band was found to shift gradually from 675 nm due to an aggregated state of Chl *a* towards 665 nm due to the monomeric state, accompanying the decrease in absorbance in proportion to the surface concentration of Chl *a*. These physical and spectral properties indicate the formation of homogenously mixed monolayer as reported for other Chl *a*–diluent systems[8,9].

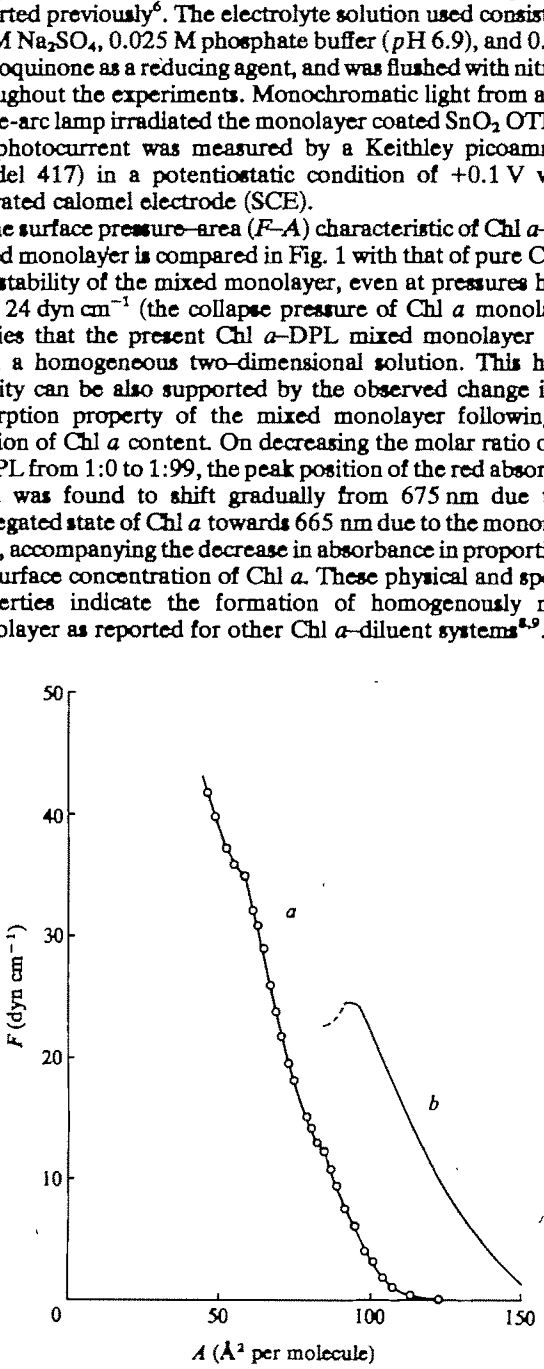

Fig. 1 *F*–*A* characteristics of a Chl *a*–DPL (1:1) mixed monolayer and a Chl *a* monolayer: *a*, Chl *a*–DpL (1:1) mixed monolayer; *b*, pure Chl *a* monolayer. Aqueous phase, 10^{-3} M phosphate buffer (pH 7.5); air atmosphere at 25 °C.

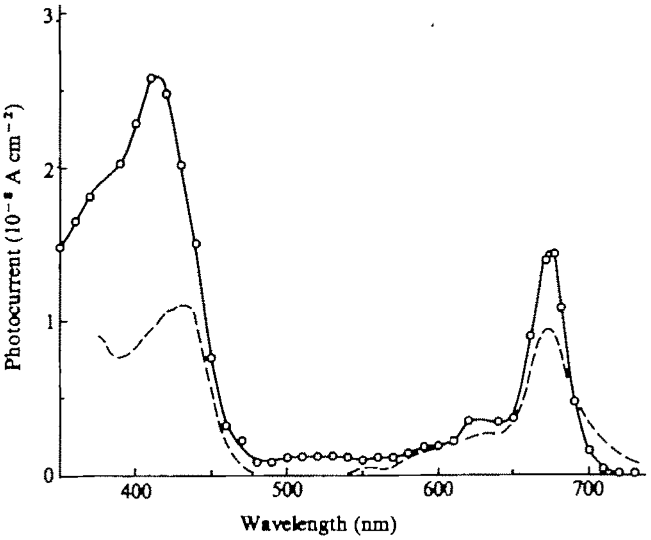

Fig. 2 Photocurrent spectrum at SnO_2 OTE deposited with mixed monolayer of Chl *a*–DPL (1:9). Dashed curve indicates the absorption spectrum of the mixed monolayer at the OTE-electrolyte interface. Composition of the electrolyte solution, 0.05 M hydroquinone, 0.1 M Na_2SO_4, and 0.025 M phosphate buffer (pH 6.9); electrode potential 0.1 V *versus* SCE; incident flux of monochromatic light, 2×10^{14} photons s^{-1} cm^{-2}.

When a Chl *a*–DPL mixed monolayer was irradiated in the electrochemical cell, an anodic photocurrent was always obtained in accordance with the electron injection from excited Chl *a* into the conduction band of SnO_2. A typical photocurrent spectrum, corrected for the slight background photocurrent of SnO_2, for the mixed monolayer of molar ratio Chl *a*–DPL of 1:9 is shown in Fig. 2. The magnitude of photocurrent corresponds to a constant incident flux of 2×10^{14} photons s^{-1} cm^{-2} at each wavelength. The photocurrent spectra coincided well with the absorption spectra of mixed monolayers at OTE–electrolyte interface. The quantum efficiencies of photocurrents were determined in terms of electrons flowing per absorbed photon, the latter could be estimated from the incident photon flux measured by chemical actinometry and from the monolayer absorbance at an OTE–electrolyte interface. The photocurrent quantum efficiencies obtained with mixed monolayers at different molar ratios are listed in Table 1, together with the calculated mean intermolecular distances between Chl *a* molecules. As the Chl *a*–Chl *a* intermolecular distance increases, the photocurrent efficiency also tends to increase, with a hypso- and bathochromic shift of the photocurrent peak positions in the red and blue regions, respectively. Such an enhancement of the quantum efficiency is attributable to the suppression of intermolecular energy transfer between Chl *a* molecules by the increase in its intermolecular distance, because the energy transfer inevitably accompanies an energy loss which eventually decrease the overall efficiency of electron injection from excited Chl *a* to SnO_2. The concomitant shifts of photocurrent peak positions are compatible with the shifts in absorption peaks described above, and the absence of the characteristic peaks due to pheophytin *a* around 400–410 nm and 500–540 nm (ref. 10) in both photocurrent and absorption spectra of mixed monolayers indicates that the pheophytin formation is effectively suppressed in the present systems; a similar stability against the pheophytinisation was recently investigated by Iriyama (ref. 11 and personal communication).

The maximum efficiency of 25±5% obtained in this work at neutral pH is relatively large, and almost twice that attained with the Chl *a*-stearic acid system[6]. Moreover, an examination of the pH dependence of the photocurrent showed that the quantum efficiency could reach 30±5% when the experiment was done in the electrolyte solution at $p\text{H} \sim 5$. These values are sufficiently larger than the quantum conversion efficiencies reported ($10^{-3} \sim 10^{-1}$) (refs 3, 4, 12–14) with other solar conversion cells using Chl *a* as a photoreceptor.

Meilanov *et al.*[15] in their attempt to verify the semiconductor model of photosynthesis, found a relatively high quantum efficiency (12–20%) for bulk photoconductive effects in metal-sandwiched dry Chl layers (0.3–2 μm thick) across which a high voltage (30–250 V) was applied. Our system is essentially different in that the photocurrent is produced by a direct electronic coupling between an excited Chl and the conduction band of SnO_2, not by an accelerating effect of the electric field across the Chl layer.

An extension of the present experiments to the construction of biomimetic membranes on SnO_2 OTE by incorporating other photosynthetically important compounds into the Chl *a*–DPL mixed monolayer would be highly promising in view of the *in vitro* simulation of the photosystem II in plant photosynthesis.

We thank Dr K. Iriyama for useful discussion, and Tien-Kai Li for technical assistance. This work was supported in part by a grant-in-aid from the Ministry of Education of Japan.

Enhanced CO_2 greenhouse to compensate for reduced solar luminosity on early Earth

CURRENT models for the evolution of the Sun require an increase in solar luminosity by 25% since the formation of the Solar System[1]. Such an increase in the solar constant should have profound effects on the terrestrial climate, but there is no evidence from the fossil record of a corresponding change in the Earth's global mean temperature[2]. This apparent conflict cannot be explained by the apparent inability of solar models to account for the low observed neutrino flux[3]. Even models that are forced to fit the neutrino data require a similar increase in the solar luminosity. As Newman and Rood[1] state: "a faint young Sun is one of the most unavoidable consequences of stellar structure considerations". We discuss here whether CO_2–H_2O in a weakly reducing atmosphere could have caused this change in the early Earth's temperature by the so-called greenhouse effect.

Sagan and Mullen[4] suggested that the solution must lie in a more efficient atmospheric greenhouse effect on Earth during the period when the solar luminosity was low. To increase the greenhouse effect, it is necessary to change the atmospheric composition, or density, or both. Sagan and Mullen[4] postulated that the atmosphere was reducing during the early history of the Earth and found that a small amount of ammonia in the atmosphere (mixing ratio 10^{-5}–10^{-6}) would provide the necessary opacity to outgoing infrared (IR) radiation to increase the mean surface temperature. In this model, the transition from reducing to oxidising conditions with the replacement of the NH_3–H_2O greenhouse by a CO_2–H_2O greenhouse comes about as a result of the development of widespread green plant photosynthesis 1,000–2,000 Myr ago. A similar route was invoked by Hart[5], who developed a more detailed model for the evolution of the atmosphere.

We agree that an enhanced greenhouse effect caused by a change in atmospheric composition is a good solution to the solar constant dilemma, but we think the NH_3–H_2O model is unrealistic. Current thinking about the early atmosphere of the Earth is shifting away from the traditional view that called for a highly reduced mixture of methane, ammonia and hydrogen, for reasons summarised by Walker[6]. More recent data have simply added strength to Walker's conclusions. As the noble gases on Mars show the same pattern of relative abundances as they do on Earth and in the 'planetary component' of the meteoritic gases, whatever fractionation process caused this pattern must have occurred before planet formation[7]. This being the case, the cosmic abundance ratio of 1.6×10^4 for H/Ne[8] gives the maximum amount of hydrogen available for a 'captured' primitive atmosphere. Using the present atmospheric partial pressure of Ne (12.7×10^{-6} bar), the maximum hydrogen partial pressure on the primitive Earth from this source was 10 mbar. As Walker[6] has pointed out, such an atmosphere would have dissipated in $<10^4$ yr. The partial pressure of ammonia in this atmosphere would have been comparable to that of neon, but its lifetime against photodissociation would have been short and it would have been out of equilibrium with crustal rocks.

Photochemical calculations by Kuhn and Atreya[9] indicate that ammonia would be irreversibly converted to N_2 on the primitive Earth in <40 yr if the mixing ratio were $\leq10^{-4}$. Eugster[10] has investigated the stability of ammonia on the primitive Earth and concluded that a mixture of N_2 and H_2 will predominate over ammonia in a normal crustal environment. Outgassing of ammonia after the last phase of accretion (or after differentiation, choosing either an inhomogeneous or homogeneous model for planet formation) seems precluded by the lack of free iron in the upper mantle[6]. As life must have begun after this phase in the planet's history, it seems reasonable to agree with Eugster[10] that any initial ammonia in the atmosphere "was oxidised to nitrogen long before the origin of life". Small amounts of methane and ammonia may have been transiently present in later times as a result of meteoritic and cometary impact, but lunar evidence indicates that bombardment rates must have been close to their present low values ~3,600 Myr ago[11].

In fact, the idea that the chemistry preceding the origin of life must have occurred in highly reducing conditions supported the traditional view of the composition of the early atmosphere[12]. But there have been sufficient demonstrations that pathways towards the formation of essential pre-life compounds can occur only in weakly reducing conditions for this argument to have lost its original force. For example, Abelson[13] was able to produce amino acids from the UV irradiation of a mixture of CO_2, CO, N_2, H_2O and just 1–10% H_2. This seems a much more reasonable composition for the post-accretion (or post-differentiation) atmosphere of the primitive Earth[6,10]. It is especially unlikely that the ammonia-containing mixture invoked by Sagan and Mullen[4] (or ammonia plus methane suggested by Hart[5]) would last for 2,000–3,000 Myr after formation of the planet. But can this weakly reducing atmosphere provide the required greenhouse effect? The answer depends on carbon dioxide and water vapour, as the other gases are ineffective absorbers of IR radiation.

We have tested this possibility by assuming that the concentration of CO_2 in the early atmosphere was much higher than the present value. We have coupled the evolutionary model for the CO_2 abundance used by Hart[5] with a radiative–convective CO_2-climate model. (We used the model as in Augustsson and

0028-0836/79/0277—0640$01 00

Table 1 Predicted global surface temperature, T_s, throughout the evolution of the Earth's atmosphere

Time (10^9 yr BP)	S (W m^{-2})	P_{CO_2} (bar)	T_s (K)	
4.25	1,039	0.31	310	(284)
3.5	1,096	0.070	296	(284)
3.0	1,133	0.033	293	(284)
2.5	1,171	0.018	292	(286)
2.0	1,209	0.0086	290	(286)
1.5	1,247	0.0029	288	(286)
1.0	1,284	0.00065	286	(285)
0.5	1,322	0.00032	287	(287)
0	1,360	0.00032	290	(290)

The solar constant, S, is taken to be $S = 1{,}020$ W m^{-2} 4,500 Myr ago and is assumed to increase linearly with time. The CO_2 surface pressure, P_{CO_2}, is from Hart[5]. Temperatures listed in parentheses refer to deletion, within the model, of weak CO_2 bands at 9–10, 12 and 18 μm.

Ramanathan[14] except that we do not include the 7.6 μm pressure-induced band of CO_2 in the present analysis, because of the lack of band absorption data for the large amounts of CO_2 considered here.) Hart's model comprises a numerical simulation of the evolution of the Earth's atmosphere over its 4,500 Myr history, accounting for time-dependent outgassing, the Urey equilibrium, the onset of photosynthesis, and crude atmospheric chemistry to develop the time-history of the CO_2 concentration. Hart also presents NH_3 and CH_4 concentrations but we do not believe that these gases would persist within the early atmosphere. Moreover, even if CH_4 were present in the early atmosphere, this constitutes a very inefficient greenhouse gas. Quite obviously Hart's attempt contains many modelling uncertainties, but at least it produces a first estimate for the variability of atmospheric CO_2 over geological time.

Although Hart[5] has considered the greenhouse effect from enhanced CO_2, as well as other gases, he uses grey gas radiation modelling. But the realities of accounting for enhanced CO_2 require a more detailed radiation model[14,15]. Moreover, Hart has used a cloud radiation model which produces strong negative climate feedback, contrary to the findings of recent cloud-climate modelling studies[16,17]. This occurs as Hart relates global cloud amount to atmospheric water-vapour content, such that his cloud amount increases with increasing planetary surface temperature. But recent model predictions suggest that the reverse occurs (see ref. 16). Hart has additionally neglected the IR opacity of clouds. Thus, in his model, a warmer planet produces an enhanced planetary albedo due to increased cloudiness, but with no compensatory IR modification, and for this reason his model gives negative cloud feedback.

In the present study, we ignore climate-induced changes in cloud-cover fraction, following the suggestion that the cloud albedo and IR modifications are compensatory[17]. Moreover, we do not attempt to incorporate ice-albedo feedback, as the extent of the polar caps seems to depend on ocean advection and, in turn, the positions of the continents which have changed considerably over geological time[18]. Even without this effect, there are substantial uncertainties in modelling ice-albedo feedback[19]. Our model mostly predicts global temperatures greater than those at present; neglect of positive ice-albedo feedback will simply produce an underestimate of these temperatures. We further assume that the Earth's surface albedo is constant and equal to its present value, ignoring changes caused by mountain building and surface vegetation.

The results of our modelling are summarised in Table 1. We have simply assumed a total atmospheric pressure of 1 bar; the predicted global temperatures are not particularly sensitive to this assumption. The solar constant was taken to be 1,020 W m^{-2} (75% of the present value), 4,500 Myr ago.

The predicted global temperatures of Table 1 suggest that enhanced CO_2 concentrations could have been the sole mechanism for preventing glaciation of the Earth when there was reduced solar luminosity. Past global glaciation would be implied by climate models in the absence of an increased atmospheric greenhouse[20]. Within the confines of our model calculations, the Earth was never more than 4 K colder than at present. This, of course, does not account for glacial–interglacial oscillations which, on our time scales, comprise short-term climatic variability.

A detailed analysis of our model results revealed that some weak bands of CO_2, which have been neglected in previous studies of this problem[4,5], contribute significantly to the surface warming. These comprise two bands at 12 μm, two bands at 18 μm, and two bands in the 9–10 μm region. Predicted global surface temperatures, deleting these weak bands within the model calculation, are included in parentheses in Table 1. Clearly, these weak bands are important for large CO_2 concentrations. In this context, the neglect of the 7.6 μm band in the present model would produce an underestimate of the computed surface temperatures by about 5–10 K for CO_2 surface pressures of the order of 0.1–0.3 bar.

Our results are quite insensitive to events occurring from 4,500 to 4,250 Myr ago. For example, if there were an initial global glaciation during this time period, due possibly to limited outgassed CO_2, the CO_2 greenhouse effect at 4,250 Myr ago would be sufficient to melt the surface ice. To show this, taking the surface albedo for an ice-covered Earth to be 0.7, we estimate the corresponding global temperature 4,250 Myr ago to be 285 K, far too high for global glaciation to persist.

We conclude that there is no need for ammonia to be present in the early atmosphere to maintain moderate temperatures when the Sun's luminosity was low. Carbon dioxide alone is sufficient, provided the partial pressure of this gas approaches the values suggested by the evolutionary model of Hart[5]. In view of the huge amount of CO_2 that has been produced over geological time and our lack of knowledge about rates at which release and deposition occurred in primitive times, this does not seem an unwarranted assumption. In fact, more detailed calculations may permit us to place a limit on the amount of CO_2 that could ever have been present in the atmosphere at one time, as the full complement (some 70 bar) would have caused excessive warming of the Earth's surface. We are also pursuing applications to the atmosphere of Mars, where larger CO_2 abundances in primitive times might have provided a sufficient greenhouse effect to permit the flow of liquid water apparently required by the evidence for fluvial erosion on that planet's surface.

The transition to an oxidising atmosphere on Earth between 2,000 and 2,500 Myr ago, brought about by green-plant photosynthesis, is then not accompanied by a transition from an NH_3–H_2O to a CO_2–H_2O greenhouse, but rather represents a simple increase in free molecular oxygen with the concomitant disappearance of CO. The composition of the intermediate atmosphere, spanning ~2,000 Myr from the early escape of hydrogen to the onset of oxygen-producing photosynthesis, was probably very similar to the present atmospheres of Mars and Venus, two planets on which any living organisms (if present) apparently have not been able to influence atmospheric composition as they have on Earth[21,22].

2,390 Myr Rb–Sr whole-rock for the Scourie dykes of north-west Scotland

THE Scourie dyke swarm intrudes the Lewisian Complex in north-west Scotland. The structural state of these basic dykes is used to subdivide the Lewisian into the pre-dyke 'Scourian' and post-dyke 'Laxfordian' complexes[1]. The ~2,700 Myr (refs 2–4) pyroxene-granulite facies Scourian gneisses of the Assynt area contain undeformed NW-trending dykes. Gneisses and dykes, which underwent the ~1,900 Myr (refs 5, 6) Laxfordian event, are now deformed and metamorphosed at amphibolite facies. Previous K–Ar measurements for the Scourie dykes in the Assynt area of the Lewisian gave a minimum age for dyke injection of 2,200 Myr (ref. 7). Younger K–Ar ages were thought to reflect later Laxfordian overprinting. I report here a Rb–Sr whole-rock isochron age of 2,390 ± 20 Myr (2σ) and an initial $^{87}Sr/^{86}Sr$ ratio of 0.7022 ± 0.0001 (2σ) for the Scourie dykes.

The Rb–Sr whole-rock method is in principle more suited to the problem of determining the emplacement age of the Scourie dykes. However, the range in Rb/Sr and measured $^{87}Sr/^{86}Sr$ ratios of the individual dykes is very small, and so any geological scatter in the data points will result in a large error in the 'fit of the isochron' and, hence, in the calculated age. Table 1 gives Rb–Sr whole-rock isotopic analyses for suites of samples from three Scourie dykes in the area of least post-2,700 Myr deformation and metamorphism at Scourie. The dykes at north and south Scourie Bay are fresh two-pyroxene dolerites[8], but the Kylesku Dyke contains amphibole replacement of pyroxene[6].

The ages and initial $^{87}Sr/^{86}Sr$ ratios of these three dykes, presented in Table 2, are all within 2 sigma error limits. Statistical tests (Student's *t*-test) show that the slopes of the isochrons are not significantly different at 95% confidence limits. There is no geological or petrological evidence to suggest that these dykes are not cogenetic or coeval. The 33 data points combined define an isochron (MSWD = 2.1) which gives an age of 2,390 ± 20 Myr (2σ) and an initial $^{87}Sr/^{86}Sr$ ratio of 0.7022 ± 0.0001 (2σ) (Fig. 1). This low initial $^{87}Sr/^{86}Sr$ ratio is within the range thought characteristic of rocks derived from upper mantle source regions at ~2,400 Myr (ref. 9). The age from this isochron is interpreted as being close in time to the primary igneous crystallisation of the dolerite dykes in the Scourie region. Combining the three sets of data has increased the range in Rb/Sr ratio and considerably reduced the calculated error on the time of emplacement. This low ±20 Myr uncertainty depends on the dykes being intruded at the same time and from the same source region. The combined Rb–Sr whole-rock age of 2,390 ± 20 Myr is considered the best estimate for the time of emplacement of the Scourie dykes investigated.

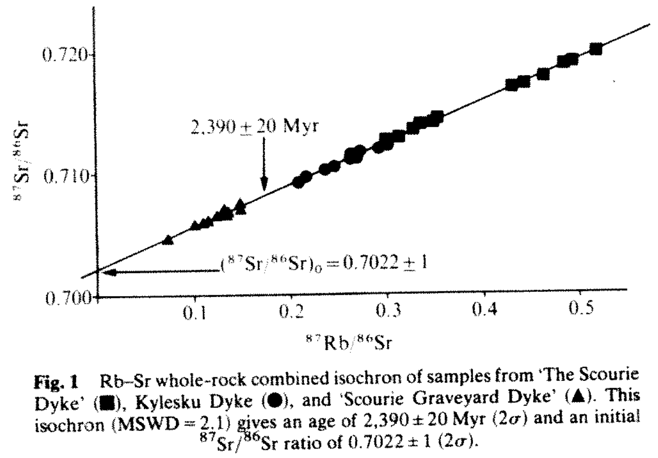

Fig. 1 Rb–Sr whole-rock combined isochron of samples from 'The Scourie Dyke' (■), Kylesku Dyke (●), and 'Scourie Graveyard Dyke' (▲). This isochron (MSWD = 2.1) gives an age of 2,390 ± 20 Myr (2σ) and an initial $^{87}Sr/^{86}Sr$ ratio of 0.7022 ± 1 (2σ).

Rubidium and strontium were separated from the 3–5-kg samples by the standard techniques used in this laboratory[6,17]. Isotope analyses were made on a 12-inch solid-source mass spectrometer using single Ta filaments[18]. Sr blank was always better than 6 ng and Rb blank less than 2 ng. Rb/Sr ratios were determined by X-ray fluorescence using extended counting times (not less than 400 s) on both peaks and backgrounds. The precision on duplicate analyses was always better than 2% or ±0.002 (whichever is the greater) and were checked against isotope dilution analyses. The value of $1.42 \times 10^{-11}\ yr^{-1}$ was used for the ^{87}Rb decay constant[19]. All errors are quoted at the 2 sigma level.

The main Scourian event formed granulite facies gneisses and NE–SW-trending structures. A later phase of NW–SE folding and associated almandine–amphibolite metamorphism has been recognised in the Assynt area[10–12]. This younger Inverian[10] event was synchronous with or occurred immediately before the intrusion of the Scourie dykes. The 2,390 ± 20 Myr date for the emplacement of the Scourie dykes provides a minimum age for this Inverian event. This is significantly older than the 2,200 Myr age previously quoted for this event[7,10–16] and perhaps indicates that the Inverian was a late phase of deformation and retrogressive metamorphism in the major Scourian event.

0028–0836/79/0277—0642$01.00

Table 2 Ages and initial $^{87}Sr/^{86}Sr$ ratios of three Scourie dykes

Locality	No. of data points	Age (Myr)	$(^{87}Sr/^{86}Sr)_0$	MSWD
North Scourie Bay	12	2,330 ± 60	0.7025 ± 3	1.4
Kylesku	11	2,380 ± 150	0.7023 ± 6	2.3
South Scourie Bay	10	2,580 ± 220	0.7018 ± 4	2.4
Mean (Fig. 1)	33	2,390 ± 20	0.7022 ± 1	2.1

The ~2,400 Myr age for the emplacement of the Scourie dyke swarm indicates that the Scourian tectonic episode had ceased by the beginning of the Proterozoic. This area of early continental crust then remained stable until the Laxfordian metamorphic and deformational event.

I thank Drs M. J. Bickle, S. Moorbath and P. N. Taylor for critical comments, John Luck for field assistance, and Roy Goodwin and Martin Humm for technical assistance. The work at Oxford is supported by the NERC.

Geomagnetic intensity in Athens between 2000 BC and AD 400

MEASUREMENTS of the intensity in Athens of the geomagnetic field between 2000 BC and AD 400 are reported here. The material from which the intensity was determined consisted primarily of sherds from the Agora excavations. Some sherds, and a whole skyphos, from the collection of the Ashmolean museum at Oxford were also sampled. The ancient intensity of the Earth's magnetic field was inferred from stepwise thermal demagnetisation. This is essentially the technique developed by Thellier[1], with the modifications described by Walton[2].

The magnetisation was measured with a Squid magnetometer which was essentially that described by Walton[2]. Of the alterations to the apparatus the major change was to move the heating oven and field coils to a position below the magnetometer. The manipulations of the specimen were accomplished pneumatically. These were controlled by a small computer which also processed the signal from the Squid, printing out the components of the magnetisation, **M**.

The laboratory field, $\mathbf{H}_z$, was applied in the vertical direction and, as described by Walton[2], an attempt was made to minimise the change in the vertical component of **M**, $\mathbf{M}_z$. In practice, the choice of field was within 10–20% of the correct value. Accordingly, values of $\mathbf{M}_z$ were obtained both with a laboratory field applied, $\mathbf{M}_z^H$, and with no field applied $\mathbf{M}_z^0$. The values of $\mathbf{M}_z^H$ were then plotted against $\mathbf{M}_z^0$ and the laboratory field corrected to give that field which would have produced a stationary value of $\mathbf{M}_z^H$. Values were also obtained for the transverse component, $\mathbf{M}_y^H$ and $\mathbf{M}_y^0$. The values of $\mathbf{M}_y^0$ were plotted against $\mathbf{M}_z^0$, and the slope of the resultant line yielded the angle between **M** and **H**. By dividing the corrected laboratory field, **H**, by the cos of this angle the estimated value of the ancient field was obtained.

Measurements were made, using the above procedure at temperatures which were nominally 200, 250, 300, 400, 500, and 600 °C (the higher temperatures were often omitted if the sample had already demagnetised sufficiently at lower temperatures).

In addition, values of $\mathbf{M}_y^H$ and $\mathbf{M}_z^H$ were obtained at intermediate temperatures. $\mathbf{M}_z^H$ was then plotted against $\mathbf{M}_y^H$. As no component of **H** was present in the transverse direction, $\mathbf{M}_y^H$ provided a measure of the degree to which the sample had demagnetised. Thus the plot of $\mathbf{M}_z^H$ against $\mathbf{M}_y^H$ could also be used to correct **H**. Both plots were used, and the value of **H** which was used was an average of the two.

Finally, the angle between $\mathbf{M}_y^0$ and some arbitrary direction in the horizontal plane was monitored. The aim of this procedure was to identify the presence of possible additional components of **M** introduced by reheating the pottery in antiquity.

Attic pottery is, on the whole, quite strongly magnetised, a magnetisation density of 10^{-3} e.m.u. cm^{-3} being typical. Thus in principle a correction for demagnetising fields due to sample shape should be applied. However, this correction would not amount to more than the difference between the value for a disk with the field applied along a diameter, or at right angles to it. As the thickness of the sample was approximately equal to the diameter this correction was negligible.

A potentially more serious problem arises from demagnetising effects due to the shape of the vessel itself affecting the moment produced during firing in antiquity. In an attempt to estimate the magnitude of this effect, samples were taken from the base, sides and handles of an Attic skyphos which had been fired between 440 and 425 BC. However, before the results could be assessed a more serious source of error had to be considered.

Rogers (personal communication) has found that pottery is anisotropic: it is easier to magnetise in a direction parallel to the plane of the pot, than it is at right angles. It is possible to correct for this effect if the anisotropy ratio—the ratio of the moment produced in the hard direction to that in the easy direction—is known. The angle between the easy plane of magnetisation and **H** is known, and if the angle between this plane and the ancient field $\mathbf{H}^A$ is known, these two angles can be deduced from the changes in direction of **M** which occur on magnetisation in the laboratory field. The derivation of this correction factor will be detailed elsewhere. It turns out that the correction is simplified considerably if the sample is orientated so that **H** is either parallel or antiparallel to the laboratory field.

The results obtained from the Attic skyphos were corrected in this way. The anisotropy ratio was adjusted to yield the best agreement between samples taken from the base and those from the side, this amounted to 0.9. For these samples, the shape correction, if any, would be less than the scatter in the data. Hence, no shape correction was made. Unfortunately, the anisotropy correction of the results for the handles proved impossible because of instrumental difficulties, and these had to be discarded.

Having done this it was impossible to identify any shape effect, except possibly for the handles. Results for the latter, however, could not be corrected for anisotropy, so an unambiguous identification of a shape effect was impossible. In any case it seems that the shape correction is less than other sources of error for samples from the side and base, and all samples used came from these locations.

The anisotropy ratio obtained from these measurements on the skyphos was used to correct the values obtained from the rest of the material. This correction amounted to between 3 and 7% (obviously it could not be larger than 10%). The corrected values for the ancient field obtained from each sherd are plotted

0028-0836/79/0277—0643$01.00

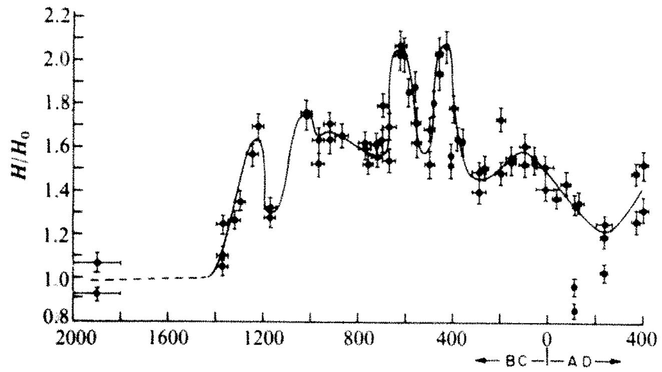

Fig. 1 The change in the ratio of the ancient intensity of the geomagnetic field $\mathbf{H}$, to the present day value, $\mathbf{H}_0$ in Athens. With the exception of the results on the skyphos each point represents a single measurement made on a core taken from a different sherd.

in Fig. 1. These results were obtained on about 80 sherds, and one whole vessel. Nine results were discarded because they displayed evidence of reheating or because alteration occurred before demagnetisation to a useful degree.

The horizontal error bars represent the archaeologists's estimate of the error in the date for the sherd in question. The vertical error bars were determined from the limits on the scatter of the results from the Ashmolean skyphos, namely ±4%. This represents quite an arbitrary estimate of the error involved in obtaining the ancient field from a fragment of pottery. The error may, in fact, be larger than this. For one thing the degree of anisotropy is not necessarily the same. Nevertheless, with few exceptions the error bars for different sherds from the same time period overlap.

The exceptions fall into two categories. First, those sherds for which the field intensity was changing rapidly. In this case a difference in time of manufacture could lead to a difference in field >8%. Second, those sherds which did not, in fact, belong to the time period assigned, but were accidentally included. This is always a possibility with deposits.

Although anisotropy is potentially a large source of error, the 4% uncertainty in our results apparently mainly arises for another reason. This is clear from the scatter in the results obtained on the four cores from the base of the skyphos. The anisotropy correction for all of these must have been very nearly the same, but they still scatter by ~±3%. In an earlier experiment[2] four slices from the same core yielded a scatter of ±3.5%. The reason for the scatter seems to lie in nonlinearities in the plots of $\mathbf{M}_z^H$ against $\mathbf{M}_y^H$ or $\mathbf{M}_z^0$. These nonlinearities occur at both low and high temperatures. The high temperature deviations are undoubtedly caused by physical or chemical alteration of the magnetic minerals. The low temperature difficulties seem to be connected with the cooling rate. At low temperatures, below ~250 °C, it seems that the relaxation times involved are long enough for the moment produced to be significantly affected by the time at temperature, and the rate at which the sample is cooled.

Finally, another difficulty should be mentioned, there was clear evidence that some of the material had been reheated to a high temperature after the initial firing. This was particularly evident in the pottery produced after AD 200. Reheating may be responsible for the increased variability in the field values which is apparent in the results for this more recent material.

The question now arises as to whether the results display the actual change in the geomagnetic intensity or just some systematic variation in the fabric. If the former is true a similar change should be apparent in other locations. Thus, it is interesting to compare these data with those obtained by Bucha[3] in Czechoslovakia. Although the details are not reproduced, the broad features of the two curves agree. In fact, Bucha's material would probably not be sufficient to show both peaks at 600 BC and 450 BC. Bucha[8] also points out that because rotation of the core leads to a westward drift of roughly 0.2° yr^{-1}; the maximum should occur at about 0 BC in America and AD 500 in Japan. Bucha[8] suggests that this is, in fact, apparent in measurements by Bucha *et al.*[4] in Mexico and the southern US, and data obtained by Nagata *et al.*[5] and Sasajima[6] in Japan.

A change in the geomagnetic intensity with time such as that shown in Fig. 1 should be useful as an adjunct to dating. It is tempting to conclude on the basis of the data from Europe, America, and Japan that the broad features of the time dependence of the field intensity at other sites may be predictable, using these data and the rate of westward drift. However, such a conclusion would be premature as this field dependence on time does not occur in all results obtained by others. Nor, if it is present, does it always occur in a time period consistent with a rate of westward drift of 0.2° yr^{-1} (see ref. 7).

The samples were obtained with the permission of the inspector of Antiquities of the Greek Archaeological Service. I thank John Camp and Mrs S. S. A. Immerwahr for material from the Agora excavations, Michael Vickers and Roger Moorey for material from the Ashmolean museum. The hospitality of the British School at Athens and the help of Hector Catling is also acknowledged. I also thank Penelope Alcock for technical assistance, M. J. Aitken for encouragement and John Rogers and Jane Fox for discussions. This research was supported by grants from the Natural Environment Research Council and the National Research Council of Canada.

Magnetic anisotropy in ancient pottery

WHILST measuring the thermoremanent magnetism (TRM) of ancient pottery to determine the field magnitude at the time of firing, by using a modification of the Thellier thermal remagnetisation technique[1], we have observed that the ease with which TRM is acquired is dependent on the angle at which the remagnetising field is applied. As a general rule it seems that the hardest direction is perpendicular to the plane of the pottery and that to a rough approximation there is an 'easy plane' lying in the plane of the pottery. The effect is apparently distinct from that due to the demagnetising field associated with sample shape, because the anisotropy effect is observed for sample shapes for which there would be no variation of demagnetising field with change of angle of applied field (such as a cylindrical sample being magnetised at various azimuthal angles in the plane perpendicular to the axis of the cylinder), as well as for samples for which the specific magnetisation is too weak for demagnetising fields to be significant. The anisotropy effect has been observed also in alternating field (750 Hz) measurement of instantaneous susceptibility.

Consideration of demagnetising fields suggests that the TRM acquired by a disk-shaped sample will be greater when the disk is orientated so that its plane is parallel to the field than when it is orientated perpendicular to the field. As reported previously[2], such a difference was observed for disks (diameter 25 mm, thickness 7 mm) of baked clay from a suite of samples for which the specific magnetisation ranged from 4×10^{-3} to $0.06\times$

Table 1 Anisotropy data for various samples of ancient pottery

	Specific magnetisation ($\mathrm{A\,m^2\,kg^{-1}} \times 10^3$)	Ratio of maximum to minimum TRM susceptibility
Romano-British coarse pottery		
(sample 559 a 1.2)	1.1	1.2
Gallo-Roman pottery (Samian ware)		
(561 a 2.1)	0.4	1.6
(1604 a 1.2)	0.3	1.7
(1604 a 4E)	0.3	1.7
Roman tile		
(1631 a)	2.2	1.2
(1631 92)	2.1	1.4
Minoan pottery (LMIA)		
(1635 a 1)	2.5	1.6
Recently fired 'ancient' pottery		
(1607 d.1.1)	3.3	1.7
(1614 c. 3.2)	3.6	1.1
Recent brick		
(IB4)	1.5	1.04

Note that the specific magnetisations quoted are for an applied field of 100 μT in the direction of minimum TRM susceptibility.

$10^{-3}\ \mathrm{A\,m^2\,kg^{-1}}$ (the numerical values are the same when specific magnetisation is expressed in $\mathrm{G\,cm^3\,g^{-1}}$). Consideration of shape demagnetisation effects alone suggested that for the weakly magnetised samples the difference would be negligible; in fact, some of the weakly magnetised samples showed a difference which was comparable with, and in one case greater than, the 30% difference shown by samples at the upper end of the specific magnetisation range. The explanation for this unexpected result may lie in the intrinsic magnetic anisotropy of the baked clay fabric.

The intrinsic anisotropy was first directly observed in squat cylindrical samples (3 mm × 3 mm) cored from Gallo-Roman pottery (Samian ware), using the SQUID cryogenic magnetometer of Walton[3]. In the modified[4] version, the oven is mounted directly below the measuring cavity and the sample, mounted with fireclay on a vertical quartz rod, can be positioned either in the oven or in the cavity. The vertical component of its magnetisation is determined from the SQUID signal resulting from the flux change in the vertical pick-up coils during movement into (or out of) the cavity. The horizontal component is determined from the amplitude of the sinusoidal variation of flux picked up by the horizontal detection coils due to rotation of the sample about a vertical axis at around 2 revolutions per second; the vertical and horizontal detection coils are connected in series to the SQUID element itself. In the oven position, controlled vertical and horizontal steady fields can be applied to the sample; in their absence the residual Earth's field is <0.5 μT because of mu-metal screening. Applied fields in the range 10–100 μT were used in the present work.

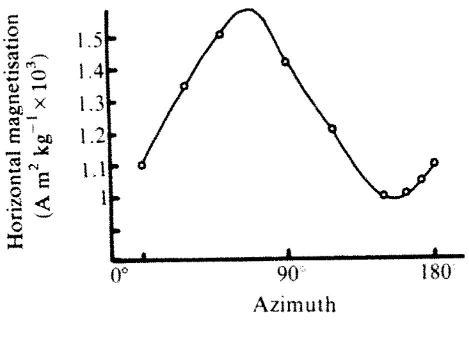

Fig. 1 Variation of TRM with direction of application of the applied field for a sample of Minoan pottery (LM 1A, sample no. 1635 a 1). The vertical scale shows the horizontal component of the TRM resulting from application of a horizontal field of 50 μT; the field was applied while the sample cooled from 500 to 150°C. The sample was a 3 mm × 3 mm cylinder cored with its axis perpendicular to the plane of the pottery. It was mounted for measurment with its axis horizontal and at zero azimuth on the scale shown; the orientation was only approximate and it is considered that the maximum is displaced from 90° because of this.

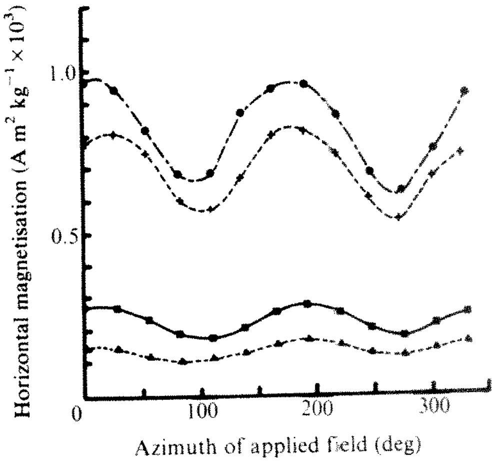

Fig. 2 Variation of TRM with direction of applied field for a sample cooled in a horizontal field of 50 μT over various temperature ranges. ●, 450–300°C; +, 300–150°C; ■, 150–20°C; ▲, 600–450°C. The data points through which the full line is drawn were obtained by cooling the samples from 150° to 20°C in the presence of the applied field. Similar curves were produced for different temperature ranges by cooling in the field from the higher temperature stated switching off the field at the lower temperature. The sample was a 3 × 3 mm cylinder mounted with its axis approximately vertical. It had been obtained by coring parallel to the plane of a piece of pottery (1607 d 1) that had been fired in AD 1962 in a replica of a Romano-British kiln at Boston, Lincs.

In Samian ware samples, for a sample cored with its cylindrical axis perpendicular to the plane of the pottery the TRM resulting from a field along the axis was 30–40% lower than the TRM resulting from the same field applied perpendicular to the axis. Conversely for a sample cored with its axis parallel to the plane of the pottery the TRM resulting from a field along the axis was 30–40% higher than for the field applied perpendicular to the axis. Table 1 lists results for this and other samples and Fig. 1 shows the variation of resultant TRM with angle of applied field for one of them. It has also been observed, for two samples at any rate, that the degree of anisotropy is the same for partial TRM's given over different temperature ranges; this is shown in Fig. 2.

A consequence of fabric anisotropy is that an applied field gives rise to a small TRM component transverse to the direction of the field unless the field is either exactly parallel or perpendicular to the 'easy plane'; if the applied field makes an angle α with the easy plane then the ratio of the transverse TRM component to the parallel component is given by

$$\frac{(a-1)\tan\alpha}{a+\tan^2\alpha}$$

where a is the ratio of the TRM susceptibility within the easy plane to the susceptibility perpendicular to that plane, the susceptibility within the easy plane being taken as uniform. This transverse component has been observed and in Fig. 3 we show the vertical TRM component resulting from application of a horizontal field at various azimuths, zero azimuth being taken as the direction of the horizontal component resulting from an applied vertical field. The maximum of the vertical component occurs at this zero azimuth as expected from consideration of the easy plane model. In contrast, the azimuthal variation of the horizontal component (resulting from the applied horizontal field) is not as predicted from the model; this is because it is masked by variation of susceptibility within the easy plane. As mounted for the measurements of Fig. 3 the ratio of the average horizontal TRM susceptibility to the vertical susceptibility was

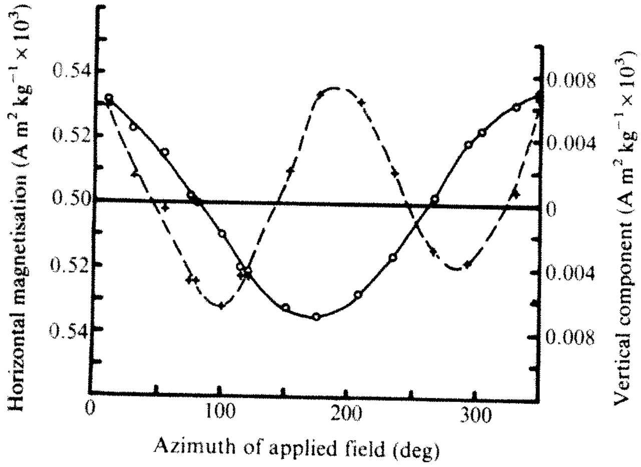

Fig. 3 Horizontal (+) and vertical (O) components of the TRM resulting from horizontal applied field of 100 μT applied at the azimuth shown, zero azimuth being taken as the direction of the horizontal component of the TRM that results from a vertical field; the field was applied while the sample cooled from 500° to 150°C. The sample was a 3×3 mm cylinder obtained from a piece of Samian ware (561 a 2.1) by coring perpendicularly to the plane of the pottery; it was mounted for measurement with its axis roughly vertical.

1.43 and application of a vertical field produced a horizontal TRM component which was 21% of the vertical component; these data indicate that the easy plane was inclined at an angle of ~25° to the horizontal and that the ratio of the average TRM susceptibility within the easy plane to the susceptibility perpendicular to it is 1.6.

The explanation that we propose for this intrinsic anisotropy in the fabric of pottery is that it is due to preferential alignment of magnetic grains. The alignment presumably occurs during the moulding of the clay into shape and that perhaps it is further enhanced by grain growth during firing. Whatever its cause the effect dictates that for reliable determination of ancient field by thermal remagnetisation it is important to apply the laboratory field in such a direction as to produce a TRM in the same direction as the magnetisation that was acquired in antiquity, or to make appropriate correction. Failure to do either could lead to an error of up to 60% in the case of the sample on which Fig. 1 is based, and to ensure that the error from misalignment is kept below 5% it is necessary to have the direction of the laboratory TRM within 10° of the direction of the ancient magnetisation, as will be seen from Fig. 1. Note that in the classic work of Thellier and Thellier[1] the samples concerned were from bricks, tiles and kilns; at any rate for the two former the data of Table 1 suggest that the effect may be relatively unimportant. The pottery listed in Table 1 is presumed to have been made on a wheel; however, the alternating field measurements included some non-wheel-made pottery of the British Iron Age and this too showed some effect. This and other aspects are being investigated further.

We thank Professor D. Walton for useful discussions, Dr. E. Hailwood for access to the AC susceptibility bridge at the University of Southampton, and Miss G. D. Bussell for the measurements on which Fig. 1 is based. This work was carried out under a grant from the National Environmental Research Council and provision of a studentship for J.M.W.F. by the NERC is also acknowledged.

Correlation between heart attacks and magnetic activity

SINCE the pioneering work of Düll and Düll[1], many papers have been published on the possible correlation between geomagnetic activity and medical phenomena. Most of them conclude that there is such a correlation, although this may reflect the tendency to publish positive results and discard negative ones, and there is widespread scepticism concerning the reality of the correlation. The main objections concern the validity of the statistical tests, failure to remove trend and inadequate allowance for seasonal variations. Here we present data for which the correlation is particularly high, and can be demonstrated convincingly by standard statistical tests.

The medical data consist of the number of cardiac emergencies admitted each day to the cardiac/thoracic wards of the main hospitals in Hyderabad and Secunderabad, the Osmania General Hospital and the Gandhi Hospital, respectively, during 1967–1972. Almost all the acute heart cases in those cities are admitted to the two hospitals except a few that are treated privately. The geomagnetic data consist of daily sums of Kp, the planetary index of geomagnetic activity for 3-hourly intervals of UT. The Kp index is intended to measure the geomagnetic effect of solar particle flux. Values of Kp are published, together with details of their definition and derivation, by the International Union of Geodesy and Geophysics[2]. The daily sums of Kp cover an interval of 24 h starting from 18 h UT, whereas Indian Time starts at 18.5 h UT, so there is a small lag of 30 min between the geomagnetic and medical data. The interval 1967 to 1972 was selected before the data were examined.

The geomagnetic data show marked variations with season, and similar variations are seen in the medical data (Fig. 1). This is to be expected if they are correlated, but the seasonal variations in the medical data might equally be due to other (for example, meteorological or dietary) causes. To eliminate such seasonal effects, and also to avoid long-term trends (which are in any case small, Table 1), we have considered the data a month at a time.

Table 1 Annual mean values

Year	Kp sum	Daily admissions
1967	15.9	2.35
1968	18.4	2.72
1969	15.9	2.51
1970	16.1	2.10
1971	16.2	2.25
1972	16.8	2.49

Table 2 lists, for each month, the coefficient of correlation, r, between the medical, M, and geomagnetic, G, parameters, and also the constants a and b for the relation $G = aM + b$, obtained by the method of least squares. The results for the first few months are presented graphically in Fig. 2; as the correlation coefficients confirm, the remaining months are essentially similar. In each case, there is a clear tendency for the number of admissions to increase with magnetic activity.

To estimate the probability of such correlations occurring by chance, Student's t test would seem appropriate, but for this test to be valid, the data need to be approximately representative of a normal distribution, and both the G and M data are heavily biased towards the lower end of their range. The standard way of making such distributions more nearly normal is to take logarithms, and this is quite satisfactory for G, but for M (which includes zero values) a constant must first be added. We have chosen the constant to be 10, as this value approximately equalises the positive and negative moments about the mean.

* Medical data are not available for 9 and 10 March, 11 and 12 April 1969.

The coefficient of correlation, r', between log G and log $(M+10)$ is given in the penultimate column of Table 2. In general, r' is similar to but slightly less than r. The final column of Table 2 lists the probability of such a correlation occurring by chance, according to Student's t test, using $t = r'/[(1-r'^2)/\nu]^{1/2}$, where ν denotes the number of degrees of freedom in the data for 1 month[3]. If the data for successive days were completely independent, ν would be $N-2$, where N is the number of days in the month. However, it is certainly true in the case of magnetic activity, and may also be true for heart attacks, that the data show considerable conservation; that is, a high value is likely to be followed by another high value; and this may considerably reduce the effective number of degrees of freedom[4]. Following Taubenheim[5], we find that, for our data, the effective number of degrees of freedom is $\nu = N/2.3-2$ for log G and $\nu = N/1.9-2$ for log $(M+10)$, and the second value of ν is that appropriate for significance tests. The values of P in Table 2 were deduced using the integral part of ν from the second relation.

From uncorrelated data we might expect 3 or 4 of the 72 correlation coefficients to achieve the 5% level of significance ($P < 5\times10^{-2}$), but we find that all except 10 are significant at this level. Similarly, we find 38 to be significant at the 1% level, and 11 at the 0.1% level, compared with 1 and 0 to be expected by chance.

Because there is no *a priori* reason to expect any conservation in the medical data, the presence of such conservation at a level similar to that in the geomagnetic data provides some additional support for the hypothesis that there is an association between the two phenomena. Also it should be noted that, although the adjustments for lack of normality and for conservation seem to complicate the analysis, had either of these been omitted, the level of significance would have appeared to be even higher.

Why should these data show such a high correlation, when those of Lipa *et al.*[6] for the times of deaths in the United States due to coronary heart disease and stroke during 1962–1966 showed no significant correlation with magnetic activity? First, the level of artificial magnetic disturbance (from cars, industry, domestic appliances and so on) is very much lower in India than in the United States. Second, they considered the time of death, which may occur much later than the medical circumstance which was its cause.

It may be objected that our data and method of analysis are not the most appropriate. Some of the admissions of cardiac emergencies may have occurred a day or more after the onset of the condition, others may have been delayed for administrative reasons (for this reason, days of zero admissions were omitted from a previous study[7]). A proportion of the cardiac emergencies may have been diagnosed wrongly. Perhaps we should have used a local measure of magnetic activity, as was done by Srivastava *et al.*[7], but, because one of us is responsible for the measurement of these, it was thought best to use an international parameter to avoid any suspicion of bias. (In any case, the difference between Kp and the local measure of K is always small.) Maybe a better result would have been obtained if we had introduced an appropriate time-lag between the magnetic and medical parameters. However, none of these possibilities would be expected to decrease the correlations, and we have analysed our data in the most straightforward way possible in the hope of convincing the reader that, in this case at least, there is a significant correlation between medical and geomagnetic phenomena.

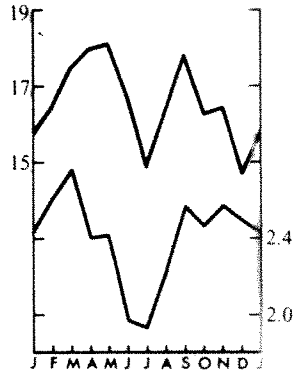

Fig. 1 Monthly mean values of the daily sums of magnetic activity indices, Kp (upper graph) and the daily admissions of cardiac emergency cases (lower graph).

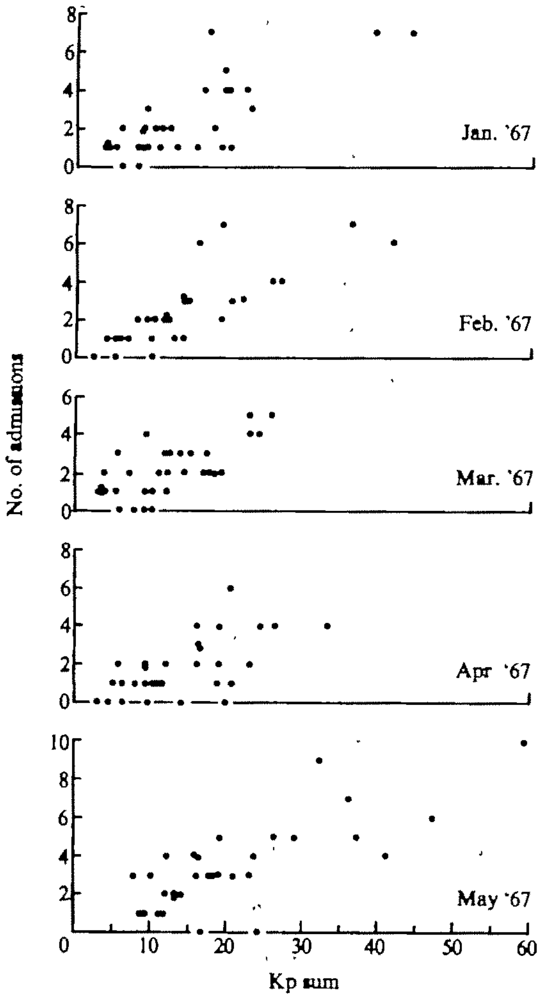

Fig. 2 Plots of daily admissions of cardiac emergency cases against daily sums of magnetic activity indices, Kp, for the first 5 months of data.

The possibility that there is some other cause (of solar origin?) responsible for both the magnetic and medical phenomena should not be ignored.

We thank the Superintendents of the Osmania General Hospital, Hyderabad, and the Gandhi Hospital, Secunderbad, for making available their hospital records, and our colleagues at the Hyderabad Magnetic Observatory for abstracting the medical data from these records.

Evidence that geomagnetic variations can be detected by lorenzinian ampullae

THERE have been several reports of electroreceptor responses in elasmobranchs to an electric field induced by various magnetic stimuli (including water flow in a geomagnetic field)[1–6]. The possibility was suggested that fish can detect telluric currents produced by geomagnetic variations[7], but it was not investigated experimentally. Here we describe direct neurophysiological evidence for such a phenomenon.

Experiments were carried out on Barents Sea skates *Raja radiata* in Dalnje-Zelenetsk Bay, on the Barents Sea. Single-unit activity was recorded as previously described[5] from nerve fibres supplying the ampulle of Lorenzini of the hyoid ampullary group. Impulses were processed by an integrator so as to follow the spike frequency in the course of the experiment.

The electrical state of the sea was monitored using two Ag–AgCl electrodes 400 m apart, parallel with the coastline. The two electrodes were connected by a marine cable to similar electrodes in the experimental tank. The electrodes in the tank were 1 m apart. To equalise the voltage gradients in the sea and the tank, two resistors (R_1 and R_2) were interposed, as shown in Fig. 1. The resistors were chosen by the following reasoning. Voltage gradient in the tank is given by

$$E_t = E_s \frac{l_s R_t}{l_t(R_l + R_1 + R_2 + 2R_e + R_t)}$$

where E_s is voltage gradient in the sea; l_s is the distance between marine electrodes, 400 m; l_t is the distance between the tank electrodes, 1 m; R_t is water resistance in the tank, 45 Ω; R_l is the overall resistance of electric line (seawater resistance + marine electrodes resistances + cable resistances), 100 Ω; R_e is the

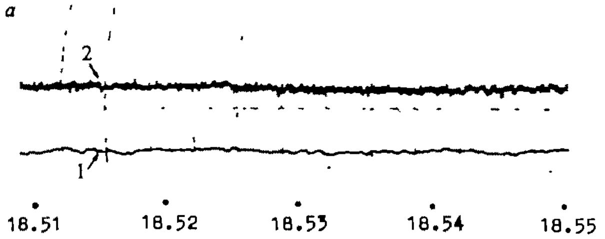
resistance of an electrode in the tank, 30 Ω; $R_1 = R_2$ are resistances in series.

To make E_t equal to E_w, R_1 and R_2 should be

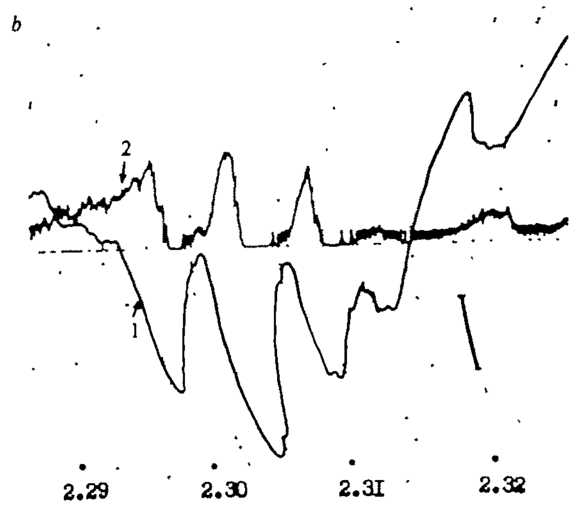
$$R_1 = R_2 = 1/2[(l_w R_t/l_t) - R_1 - 2R_e - R_t] \approx 9 \quad \text{k}\Omega$$

To estimate the electroreceptor unit response to natural stimulus, spike frequency was compared to the magnitude of the voltage gradients produced by telluric currents. Magnetic field variations were registered.

Measurements were made during a magnetic substorm which appeared together with the polar light on 25–26 February, 1978. The rate of change in the geomagnetic vertical component at the time when measurements were made was 0.2 to 1.0 nT s^{-1} (2×10^{-6}–10^{-5} G s^{-1}); maximal deviation from the background field was 216 nT. Short-period (1–3 min) oscillations of telluric voltage gradients were observed to be synchronous with variations of the geomagnetic field. Voltage gradients in the sea (and, consequently, in the tank) were from ±0.6 μV cm^{-1} to (at times) ± 1.25 μV cm^{-1}.



25 February 1978



26 February 1978

Fig. 2 Synchronous recording of induced electric field in the sea (1) and the time course of spike frequency of a single electroreceptor (2) before (*a*) and during the magnetic substorm (*b*). Vertical bar: 0.2 μV cm^{-1}, 15 imp s^{-1} (GMT).

Figure 2 shows that electric field oscillations due to geomagnetic variations produced a clear-cut response in the electroreceptors, as judged by corresponding changes in spike frequency. The spike frequency was sensitive not so much to the absolute value of the electric field as to its rate of change, that is, the field derivative with respect to time. Such a response may be due to adaptation of the receptor to a prolonged stimulus. Receptor sensitivity was sufficient to detect a change in the electric field as small as 0.006 μV cm^{-1} s^{-1}.

These measurements clearly indicate that the ampullae of Lorenzini can detect the electric field induced by variations of the Earth's magnetic field. This capacity is likely to be more strongly expressed within the coastal area, and this could be the result of an enhancement of telluric currents near the coast due to 'coast effect' (ref. 8). Such a suggestion agrees with experimental data indicating that the electroreceptor response associated with changes in magnetic field is maximal when a fish is near the wall of a tank[6]. The marine electrodes in our experiments were placed in a bay screened from the open sea by islands which reduced the coast effect of telluric currents[9]. Otherwise, the effects observed might have been greater.

Further studies should provide information about the biological role and practical applications of the detection of telluric currents by fish.

Correlation between heterozygosity and subunit molecular weight

GENIC heterozygosity at enzyme loci has been examined for correlation with parameters as diverse as substrate specificity[1], physiological function[2] and quaternary structure[3]. However, none of these has provided an adequate explanation for allozymic variation in general. One report[4] suggested a positive relationship for *Drosophila* enzymes between heterozygosity and subunit molecular weight (MW), which can be equated to the size of the structural gene element. Various models, both neutral and selective, would predict a correlation between gene size and variability[5–7]. Recently, a similar correlation has been found within three classes of vertebrates[8,11], and between the number of rare alleles and subunit size in human populations[9,10]. We report here that we have tested the relationship between heterozygosity and subunit size in *Drosophila* species with a new selection of enzymes. Our results indicate that the correlation is indeed general. The relationship is quasi-linear and does not differ significantly from several models. The results support the hypothesis that there are constraints on the number of sites available to charge substitution within an enzyme molecule.

For our test we used data on six of the enzymes used by Koehn and Eanes[4] and estimated the MWs on a series of at least seven enzymes in *Drosophila melanogaster* for which such information was not previously available. We excluded several enzymes from our analysis because of inadequacies in the data. No esterases or phosphatases were used as their homology across *Drosophila*

0028–0836/79/0277–0649$01 00

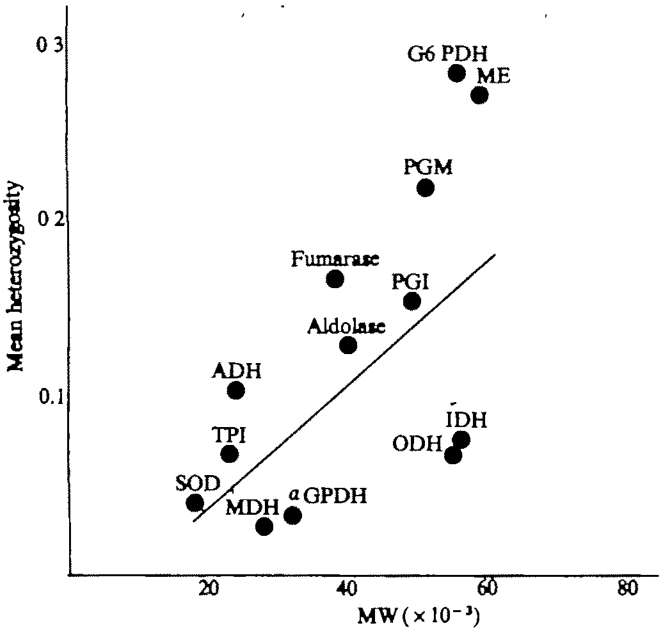

Fig. 1 Mean heterozygosity as a function of MW. SOD, 18,000; TPI, 23,000; ADH, 24,000; MDH, 28,000; αGPDH, 32,000; fumarase, 38,000; aldolase, 40,000; PGI, 49,000; PGM, 51,000, ODH, 55,000; G6PDH, 55,000; IDH, 56,000; ME, 58,000. Each point represents the mean heterozygosity value for an enzyme over all species surveyed for that enzyme. The regression line indicated ($y = 0.00000353x - 0.0289$) was calculated from the full data set of 118 observations (which is available on request).

species is not clear. In addition to these restrictions on the enzymes used we have made a new selection of population data. In so doing, we only used data from those sources which permitted calculation of the actual numbers of each allele observed. However, whereas Koehn and Eanes[4] did not consider samples where an enzyme was completely monomorphic, we included all such samples.

The sedimentation constants ($s_{20,w}$) of phosphoglucose isomerase (PGI) and triosephosphate isomerase (TPI) were estimated from sucrose density gradients[11], relative to *D. melanogaster* alcohol dehydrogenase (ADH) and rabbit muscle lactate dehydrogenase (LDH). The means and standard errors of six estimates were: PGI, 6.6±0.23; TPI, 4.5±0.13. Stokes' radius estimates of 35.5 Å and 28.6 Å, respectively, were obtained from gel filtration relative to three standards[12]. From these data, the native MWs of these enzymes were calculated to be 97,000 for PGI, and 47,000 for TPI, assuming a partial specific volume of 0.725 $cm^3 g^{-1}$.

The MWs of enzymes with too little activity for convenient assay in the sucrose density gradients were estimated directly from gel filtration chromatography[13]. Relative to five standards, the native MWs of fumarase, isocitrate dehydrogenase (IDH) and phosphoglucomutase (PGM) were estimated as 150,000, 112,000 and 51,000, respectively. Full data on the MW determinations of these and other *Drosophila* enzymes will be published elsewhere.

The enzymes used in investigating the relationship between heterozygosity and subunit size were: TPI, PGI, IDH, fumarase and PGM from above; malic enzyme (ME) and glucose 6-phosphate dehydrogenase (G6PDH) for which direct estimations of subunit size (58,000 and 55,000) have been made in our laboratory from purified enzyme[14], and, from Koehn and Eanes' analysis[4], superoxide dismutase (SOD), malate dehydrogenase (MDH), α-glycerophosphate dehydrogenase (αGPDH), octanol dehydrogenase (ODH), aldolase and ADH. The structures of the new enzymes have been established mainly by starch-gel electrophoresis. Other work in progress in our laboratory has necessitated the collection of variants at all these loci in *D. melanogaster*. From this work, TPI, PGI and IDH have been deduced to be dimers from the appearance of three clear bands in heterozygotes, whereas PGM is a monomer and fumarase and aldolase are tetramers (R. A. Voelker and C.H.L., unpublished data). For the remaining enzymes, the structure given by Koehn and Eanes[4] was assumed.

The population data used in the analysis were carefully selected, as has been described. (They were taken from refs 15–25 and from unpublished data of F. J. Ayala.) Where more than one suitable sample was available for a species, the data were pooled so that each species was given equal weight. Data from a total of 15 species were used in the analysis. The correlation analysis was carried out on the new enzyme set, on the set used by Koehn and Eanes, and on both combined. A non-parametric test for rank correlation was made using Kendall's τ, as neither variable is normally distributed, and the results are given in Table 1. It can be seen that there is a highly significant correlation between heterozygosity and subunit MW in the combined data set. Figure 1 shows the distribution of the data and a least-squares regression line which was fitted to the whole data set. For clarity, only one point is shown for each enzyme, the mean value taken over all species with data for that enzyme.

We have been able to confirm the conclusion of Koehn and Eanes[4] that there is a positive correlation between allozymic heterozygosity and subunit MW. Having made a stringent selection of the data and used a test of reduced power we are satisfied that this relationship is general. Nei *et al.*[10] have recently examined the relationship between MW and heterozygosity in vertebrates and obtained a significant correlation on data from three classes. These authors claimed that the magnitude of their correlation was "roughly" in agreement with the predictions of a neutral model. We have examined our data in a similar way and have also found agreement between our correlation and the predictions of both the infinite alleles[5] and the charge-state models[26]. However, the regression line has a wide confidence belt and almost any model which predicts a positive monotonic relationship between the two variables would also fit our data. Two alternative such models are those of Gillespie[6] and Watterson[7]. In Gillespie's random-environments model the heterozygosity at a locus depends inversely on the relative effect of a substitution on enzyme function. In general, the larger an enzyme molecule, the smaller would be the relative effect of a mutation. In Watterson's stochastic heterotic model heterozygosity is as predicted by the infinite-alleles model when $\sigma = 2N_e s = 0$. We found that although the predictions diverge as σ increases, for $\sigma = 0(1)$ this model does not differ greatly from the neutral case in the region of heterozygosity values of our data.

We have also carried out a two-way analysis of variance on our heterozygosity data by gene and species, and the results

Table 1 Correlation between allozymic heterozygosity and subunit MW

Data set	Kendall's τ	Probability of a higher τ value
(1) TPI, PGI, IDH, PGM, ME, fumarase, G6PDH	0.159	0.13
(2) ADH, Aldolase, SOD, MDH, ODH, αGPDH	0.102	0.26
(3) All data—(1)+(2)	0.213	0.0013

The MWs of TPI and PGI were determined by sucrose density gradient sedimentation and those of fumarase, IDH and PGM by gel filtration on Sephacryl S-200. The structure of these enzymes was determined by starch-gel electrophoresis as described in the text. Subunit sizes were thereby assigned as follows: TPI, 23,000; PGI, 49,000; fumarase, 38,000; IDH, 56,000; PGM, 51,000. Subunit sizes for ME (58,000) and G6PDH (55,000) have been determined from purified enzyme. Data set (1) consists of those enzymes whose MW was not previously known. Data set (2) consists of enzymes previously used in the analysis of Koehn and Eanes[4]. In each case new population data were selected as indicated in the text. Note that G6PDH was used in Koehn and Eanes' analysis[4]. It is included in data set (1) because a new MW determination is available which represents a substantial change from the value previously used.

Table 2 Analysis of variance of heterozygosity by gene, species and MW

	Sum of squares	Degrees of freedom	Variance component per observation
Species	0.4792*	14	0.0041
Gene	0.6365†	12	0.0055
MW	0.2328		0.0020
Other gene effects	0.4037		0.0035
Error	1.7973	91	0.0153
Total	2.913	117	0.0249

The analysis of variance was first carried out by gene and species on the full data set. The component of the variance due to gene effects was then partitioned into that due to MW and that due to other gene-specific effects as described in the text. The level of significance of the correlation with MW is given in Table 1.
*Significant at 5% level.
†Significant at 1% level.

(Table 2) show significant effects due to both. We have calculated the correlation coefficient between heterozygosity and MW, corrected for species effects ($r = 0.309$; $P < 0.01$). Following Nei *et al.*[10], r^2 is the ratio of the co-variance between gene-average heterozygosity and MW to the product of the variance in MW and the total variance in heterozygosity less that due to species. We were thus able to divide the genic component of the variance into that due to MW and that due to other gene effects. By partitioning the variance in heterozygosity in this way, we have been able to compare the component due to MW with that due to species. We find (Table 2) that the variance component due to MW is about half that due to species.

In the infinite-alleles model of Kimura and Crow[5], heterozygosity is determined by the product of effective population size and mutation rate. Assuming that the latter is proportional to structural gene size, it is interesting that the variance component of our data that is due to MW is so large relative to the species effects, as there is only a threefold range in MW. This would suggest that in equilibrium conditions the range in total population size, being the main species effect under this model, would be of the order of sixfold. We consider this a challenge to the infinite-alleles model. Although one possible interpretation could be that the effective population number of these 15 *Drosophila* species only varies to a similar degree, this is unlikely as the sample includes both equatorial forest species (for example, *D. willistoni*) and cactophilic species (*D. arizonensis*). It could also be argued that they have not attained equilibrium due to fluctuations of population size, but it seems more plausible to us that there are general constraints on the number of sites in a gene where a charge substitution is 'evolutionarily acceptable'. This alternative has been suggested by the analysis of the evolution of amino acid sequence in cytochrome *c*, fibrinopeptide A and haemoglobin[27–29]. Werhahn and Gulizia[30] have pointed out that the effect of population size on equilibrium heterozygosity decreases with the number of mutable sites. Thus, the infinite-alleles model is not consistent with all aspects of our data, and although it could be said to predict a correlation between heterozygosity and MW, so could several other models.

We thank Dr D. Shah for assistance with the sucrose density gradient sedimentation and Dr Brian Charlesworth for discussions.

Acetylcholine-elicited responses in primary and secondary mammalian oocytes disappear after fertilisation

THE recent finding[1] of acetylcholine (ACh) receptors on the amphibian oocyte membrane raises two main questions: (1) is the presence of ACh receptors a feature common to all vertebrates including mammals, and (2) does the sensitivity to ACh undergo developmental changes throughout oocyte growth and maturation, or following fertilisation? We have investigated these problems using conventional electrophysiological techniques, and show here that depolarising and/or hyperpolarising membrane potentials are elicited by ACh in mouse dictyate and metaphase II oocytes, but not after fertilisation.

Fully grown dictyate mouse oocytes from antral follicles (see legend to Fig. 1 for technical details) had a resting membrane potential ranging from −20 to −40 mV(-27.1 ± 1.1, mean ± s.e.m., $n = 57$). When these cells were perfused with a medium containing 1×10^{-4} to 2×10^{-2} M ACh, a dose-dependent membrane depolarisation usually occurred (Figs 1, 2*a*). The ACh-elicited depolarisation took many seconds to develop, as previously shown in *Xenopus* oocytes[1], and the delay between ACh application and the onset of the response was never shorter than 15–20 s. Such a delay was not significantly modified by increasing the bath temperature to 37 °C. At lower ACh concentrations (1×10^{-8}–1×10^{-5} M), the response to ACh differed among the oocytes studied. Some oocytes underwent membrane hyperpolarisation after an initial depolarisation, whereas others displayed only the hyperpolarising response, or no resting potential change at all. The hyperpolarising response was only occasionally observed at high ACh doses (up to 2 mM)(Fig. 2*b*). Both depolarising and hyperpolarising ACh potentials gradually 'desensitised' during maintained application of the drug (Fig. 2*a*, *b*), and preliminary exposure of oocytes to ACh concentrations as low as 10^{-11} M completely prevented all membrane responses to maximal ACh doses (up to 2×10^{-2} M). The ACh-elicited depolarisation was associated with a significant decrease in membrane input resistance (see legend to Fig. 1 for technical details), whereas the hyperpolarisation was accompanied by a significant increase in membrane input resistance. Ionophoretic application of ACh on to oocyte membrane occasionally elicited very small depolarising or hyperpolarising responses in antral oocytes, and here again these responses took many seconds to develop, as previously shown in *Xenopus* oocytes[1].

0028–0836/79/0277—0651$01.00

Incubation of antral mouse oocytes in Ca^{2+}-free (Ca^{2+} replaced by Mg^{2+}), Na^+-free (Na^+ replaced by choline), or K^+-free (K^+ replaced by Na^+) media did not seem to modify the ACh-elicited depolarisation. However, in the presence of Cl^--free medium (Cl^- replaced by SO_4^{2-} or propionate), the ACh depolarising response was enhanced, although a maintained incubation of the cell in Cl^--free medium completely prevented the depolarising response. These findings apparently indicate that chloride ions are involved in the ACh-elicited depolarisation. Similar conclusions were drawn in *Xenopus* oocytes[1]. Similarity between amphibian and mammalian oocyte ACh receptors is further indicated by the ineffectiveness of (+)tubocurarine (up to 10^{-4} M) in blocking responses in antral mouse oocytes, and by the effectiveness of atropine (10^{-7}–10^{-6} M) in preventing ACh membrane depolarisation. Atropine did not seem to abolish the ACh-elicited hyperpolarisation.

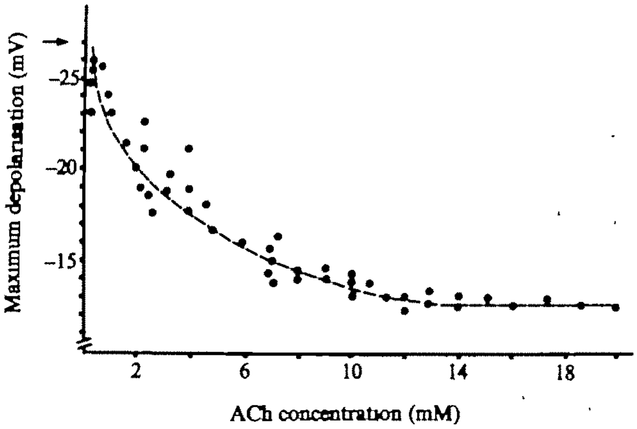

Fig. 1 Depolarising response of antral mouse oocytes in the presence of increasing ACh concentrations. The maximum depolarisation level after ACh perfusion obtained in 47 independent determinations is plotted against the corresponding ACh concentration in the perfusion bath. The arrow indicates the mean membrane resting potential of the tested cells. Swiss CD1-COBS mice from Charles River Italia were used in all experiments. Dictyate oocytes at an intermediate stage of growth (vitellus diameter 60–65 μm, pre-antral, from follicle stages 5a and 5b, ref. 2) and at the end of growth (vitellus diameter 75–85 μm, antral, from antral follicles) were obtained mechanically, by pricking infant (pre-antral) and adult (antral) ovaries with a needle, and were completely freed from surrounding granulosa cells by gentle pipetting in phosphate-buffered saline (PBS) supplemented with pyruvate, lactate and bovine serum albumin. Metaphase II oocytes and fertilised eggs were obtained from mice treated with pregnant mare serum and human chorionic gonadotropin, and isolated from cumulus cells by brief exposure to hyaluronidase in PBS. Following isolation, oocytes and eggs were carefully washed in the complete bath medium of Okamoto *et al.*[3] and immediately processed for electrophysiology. Experiments were routinely carried out at room temperature (23–25 °C) in a 1 ml perfusion bath. Similar results were obtained from control experiments carried out at 37 °C. Glass microelectrodes filled with 1.5 M K acetate (resistance 15–30 MΩ) were used in all experiments. Determinations of membrane resistance were made with the aid of a modified bridge circuit[4,5] by a series of brief hyperpolarising pulses of a few mV amplitude.

To investigate whether ACh sensitivity changes throughout oocyte growth, we have examined pre-antral oocytes at an intermediate stage of cell growth. A mean resting potential of -39.3 ± 4.3 mV ($n = 12$) was found in pre-antral oocytes. These cells responded to both high and low ACh doses mainly by membrane hyperpolarisation accompanied by an increase in input membrane resistance. Few cells underwent ACh depolarisation up to -25 and -30 mV (10^{-4}–10^{-2} M ACh), and here a decrease in membrane resistance was observed. Taken together, these findings indicate that ACh sensitivity is a constant feature of dictyate mouse oocytes, at least from intermediate to terminal stages of cell growth. The depolarising ACh response apparently reached a maximum at the end of the cell growth period, that is, with the appearance of the antrum inside the follicle.

In metaphase II oocytes, a mean resting potential of -24.3 ± 1.4 mV ($n = 12$) was observed, in agreement with previous observations[3]. These oocytes responded to ACh with a pattern of membrane potential depolarisation and/or hyperpolarisation similar to that observed in the antral cells.

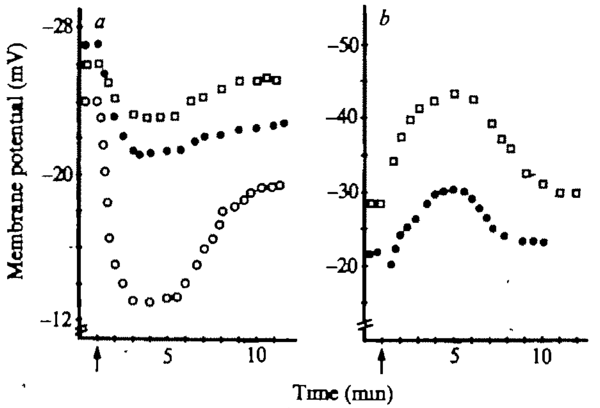

Fig. 2 ACh-elicited depolarisation (*a*) and hyperpolarisation (*b*) in five antral mouse oocytes treated with different doses of ACh. Following ACh application (arrow), a depolarising or hyperpolarising response gradually developed, and the maximum level of response was attained after 2–4 min. Note desensitisation after prolonged exposure of the cells to the drug. *a*: □, 0.5 mM; ●, 2 mM; ○, 7 mM. *b*: □, 10^{-7} M; ●, 2 mM.

Fertilised eggs had a membrane potential (-41.8 ± 3.1, $n = 34$) higher than that of unfertilised oocytes, in agreement with previous observations[6]. Unlike primary and secondary oocytes, fertilised mouse eggs displayed no ACh-elicited responses. ACh doses ranging from 10^{-4} M up to 1.5×10^{-2} M did not elicit any change in membrane potential and input membrane resistance in eggs collected at various times after fertilisation (5–20 h). We have also tested two-cell embryos (membrane resting potential -48.4 ± 2.2 mV, $n = 6$), and here again we did not observe any ACh response. Therefore, the disappearance of cholinergic response is an early event following fertilisation, lasting at least until the two-cell stage of embryonic development. It would be interesting to know whether this disappearance of oocyte ACh sensitivity following fertilisation is directly related to sperm penetration. We favour this hypothesis, as preliminary experiments have shown that responses to ACh are still present in both spontaneously activating and Sr^{2+}-activated mouse eggs (see ref. 7 for parthenogenetic activation of mouse eggs).

We conclude that ACh sensitivity is probably a general feature of vertebrate oocytes, even if in the mouse it is lower than in the amphibians[1]. Mouse oocyte sensitivity to ACh undergoes developmental changes throughout oocyte growth, and it is not grossly affected by the maturation process at ovulation. Finally, ACh sensitivity is a property peculiar to primary and secondary oocytes, as it is lost following fertilisation. This suggests that ACh receptors in vertebrate oocytes may have some specific role in the maturation and/or fertilisation processes.

We thank Professor R. Miledi and Dr J. Stinnakre for suggesting this work and for discussion, Professors A. Curatolo and V. Monesi for critical reading of the manuscript, and M. Pompili, S. Rapino and C. Rattazzi for help. This research was carried out under CNR Research Project Biology of Reproduction grants 77.00344.85 and 77.00348.85, and was supported in part by the Ford Foundation.

Hypothalamic enkephalin neurones may regulate the neurohypophysis

WE have previously reported that significant amounts of immunoreactive (ir)-Leu^5-enkephalin were present in extracts of the neurointermediate lobe of the rat pituitary[1]. Negligible amounts of the pentapeptide were detected in the anterior lobe. In these assays, the concentration of Leu^5-enkephalin in the neurointermediate lobe was higher than in the globus pallidus, the brain region reported to contain the densest enkephalinergic innervation[2]. The high content of (ir)-Leu-enkephalin in the neurointermediate lobe of the pituitary led us to further investigation of its distribution and possible function. We report here that (ir)-enkephalins in the pituitary are concentrated in nerve fibres projecting from the hypothalamus to the pars nervosa and that this pathway may be involved in the regulation of neurohypophysial neurosecretion.

Under a dissecting microscope the rat pituitary could be easily separated into the anterior lobe (pars distalis) and the neurointermediate lobe, and the latter dissected into pars nervosa and the lobules of the pars intermedia. The isolated elements of single pituitaries were each then homogenised and assayed by radioimmunoassay[1,3] for β-endorphin, and Leu^5-enkephalin (Fig. 1). The major portion of (ir)-Leu^5-enkephalin (76%) was found in the pars nervosa. In using a radioimmunoassay for Met^5-enkephalin described elsewhere[4], we found that the pars nervosa contained 1,920 ± 240 pg ($n = 5$; mean ± s.e.m.) of (ir)-Met^5-enkephalin. The ratio of (ir)-Met^5-enkephalin to (ir)-Leu^5-enkephalin was ~3, a similar value to that found in other rat brain areas rich in enkephalins[4]. (ir)-β-endorphin was almost absent from the pars nervosa, but was present in both pars distalis and pars intermedia, as indicated in previous studies[1,5].

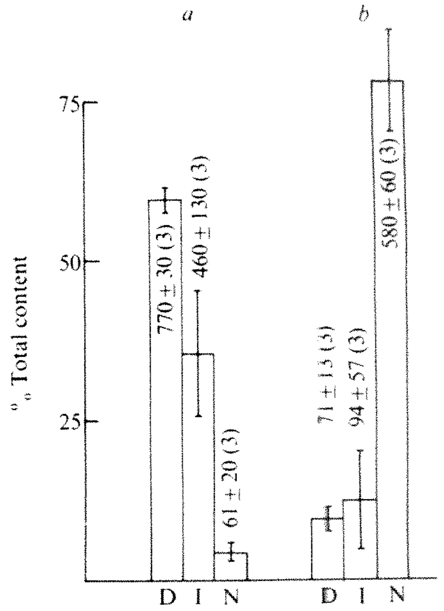

Fig. 1 Pituitaries of Sprague-Dawley male rats (200 g) were dissected under the microscope and pars distalis (D), pars intermedia (I) and pars nervosa (N) were extracted in hot 1 M acetic acid as described in ref. 3, which also contains the complete procedure for the radioimmunoassays of β-endorphin and Leu^5-enkephalin. Dose–response curves of the pituitary extract shows parallelism with synthetic Leu^5-enkephalin. Gel filtration of the extracts on a Bio-Gel P-60 column (50 × 0.7 cm) equilibrated in 50% acetic acid showed that all the (ir)-Leu^5-enkephalin was eluted in a symmetrical peak indistinguishable from that obtained with synthetic Leu^5-enkephalin. Neither vasopressin (AVP or LVP) nor oxytocin crossreact in our Leu^5-enkephalin radioimmunoassay at doses up to 100 g per assay tube. *a*, β-endorphin (ng per pars); *b*, Leu^5-enkephalin (pg per pars).

Table 1 (ir)-Leu^5-enkephalin in neurointermediate lobe after hypothalamic lesions

	pg per lobe (mean ± s.e.m.)
Controls (6)	503 ± 31
Paraventricular nucleus lesions (8)	289 ± 21*
Paraventricular and supraoptic lesions (2)	55

Discrete anodal lesions were made with stainless steel wires, insulated to the tips and stereotaxically positioned in the paraventricular nuclei or in both paraventricular and supraoptic nuclei of male, Sprague-Dawley rats (250 g). Control lesions were placed in the cortex. Seven days after lesioning, radioimmunoassay for Leu^5-enkephalin was carried out on neurointermediate lobes extracted in 1 M acetic acid as described in Fig. 1. All lesion sites were histologically verified. Numbers in parentheses refer to the number of animals tested.

*$P < 0.001$, *t* test.

Using a peroxidase-coupled goat anti-rabbit IgG for indirect immunocytochemistry[6], fine varicose nerve fibres showing Leu^5-enkephalin immunoreactivity were localised in the pars nervosa. These fibres were concentrated on the perimeter of the neural lobe and more or less absent from the centre of the tissue (Fig. 2*b*). Fibres with similar immunoreactivity could be traced in favourable sections through the pars tuberalis (pituitary stalk), and as reported by others, were also present in supraoptic and paraventricular nuclei (ref. 7 and Fig. 2*a*).

The antiserum also stained corticotroph cells of the anterior lobe and all cells of the pars intermedia. As these intermediate lobe cells contain high amounts of β-endorphin, postmortem degradation by peptidases could have given rise to Met^5-enkephalin in sufficient amounts to be detected by our enkephalin antiserum.

After pretreatment with colchicine, (ir)-Leu^5-enkephalin cell bodies were visualised in the paraventricular (Fig. 2*a*) and supraoptic nuclei of the hypothalamus. Varicose fibres from these neurones could be traced through the lateral hypothalamic area, along the course followed by magnocellular neurosecretory axons. Lesioning experiments further suggest that the enkephalinergic cell bodies in the magnocellular nuclei have projections in the pars nervosa. Six days after sectioning the pituitary stalk or lesioning the medial basal hypothalamus, (ir)-enkephalinergic fibres were absent from the pars nervosa.

0028-0836/79/0277—0653$01.00

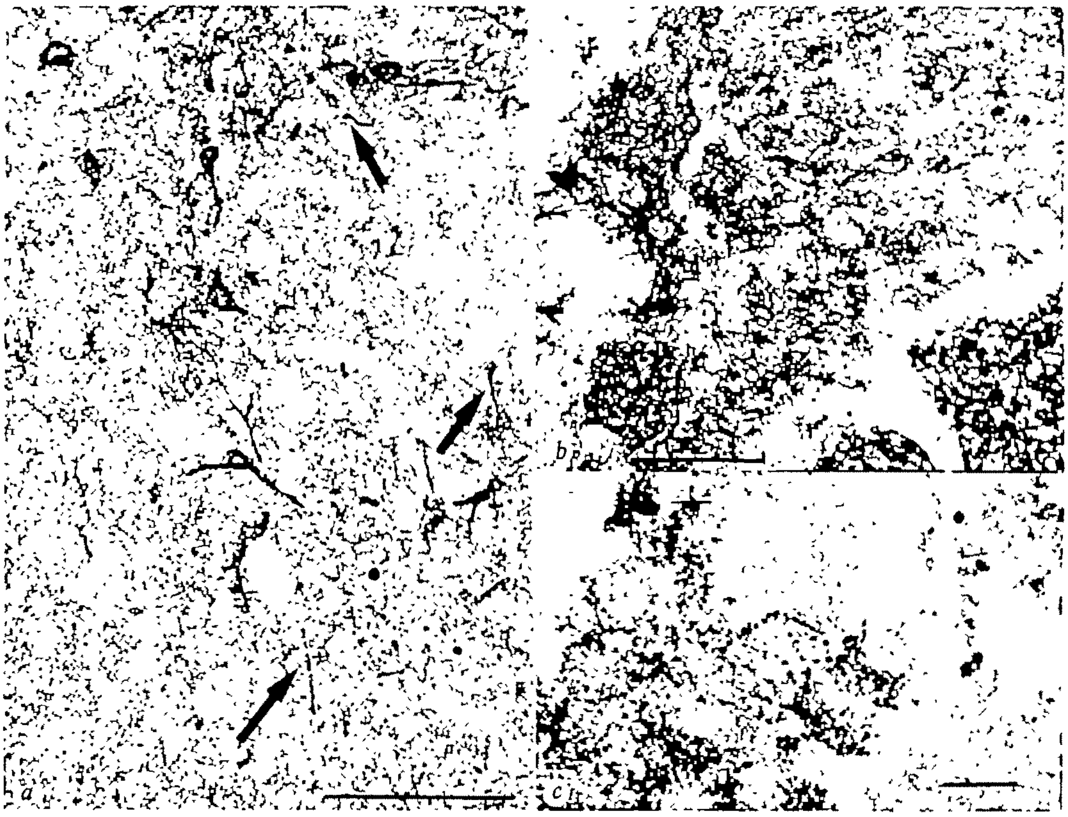

Fig. 2 Photomicrographs of rat hypothalamus (*a*), and neurohypophysis (*b*, *c*) reacted with rabbit anti-Leu^5-enkephalin and a horseradish peroxidase-tagged goat anti-rabbit IgG, as described elsewhere[9]. *a*, After intracerebroventricular colchicine (25 µg, 24 h) neurones in the lateral pole of the paraventricular nucleus exhibit positive immunoreactivity in their dendrites, perikarya and in some finer varicose processes (arrow) presumed to be axons. *b*, Neurohypophysis and intermediate lobe (lower right) of normal rat. Fine varicose immunoreactive fibres can be seen only at the perimeter of the neurohypophysis. Cells of the intermediate lobe show general cytoplasmic immunoreactivity. *c*, Higher magnification view of immunoreactive fibres at the perimeter of the neurohypophysis. Fibres identical to these were seen in occasional patches in Brattleboro rats pretreated with colchicine (24 h, 25 µg), but in untreated Brattleboro rats, no neurohypophysial immunoreactivity was observed. Note that at this higher magnification, the immunoreactive fibres seem to be enveloping groups of non-reactive axons at the perimeter of the neurohypophysis. Calibration bars: *a*, 50 µm; *b*, 25 µm; *c*, 10 µm.

As shown in Table 1, radioimmunoassay measurements confirmed that discrete damage to the paraventricular nucleus resulted in a 40% decrease in the levels of (ir)-Leu^5-enkephalin in neurointermediate lobe extracts. Further damage to the supraoptic nucleus reduced levels to 10% of controls.

The detection of a neuronal pathway between enkephalin-immunoreactive neurones in the magnocellular hypothalamic nuclei and enkephalin-(ir) terminals in the pars nervosa suggests at least two possible functional roles. As with other neurohypophysial hormones, enkephalin could be released as a neurohormone into the bloodstream with vasopressin or oxytocin. Alternatively, enkephalinergic fibres could somehow interact with the secretion of neurohypophysial hormones. Indeed, we find that salt loading decreases (ir)-Leu^5-enkephalin in the neurointermediate lobe (Table 2). Five days after substitution of 2% NaCl for drinking fluid, the vasopressin stores in the neurohypophysis decrease to ~20% of control[8]. In these conditions, we find that (ir)-Leu^5-enkephalin content drops to 37% of control. However, this degree of dehydration did not affect β-endorphin levels in the anterior and intermediate lobes of the pituitary (Table 2). (ir)-Leu^5-enkephalin levels were also not changed in the hypothalamus during this treatment.

Levels of thyrotropin-releasing hormone (TRH) and somatostatin in these extracts were also determined, using radioimmunoassays described elsewhere[9,10]. These two peptides are highly concentrated in the hypothalamus and also in the neurointermediate lobe of the pituitary (ref. 19 and W. Vale, personal communication). In the neurointermediate lobe we found 120±16 pg of (ir)-TRH per lobe ($n = 6$) and 810±220 pg of (ir)-somatostatin per lobe ($n = 6$). Neither pituitary nor hypothalamic levels of TRH and somatostatin were affected by dehydration, indicating that the mechanisms producing the (ir)-Leu^5-enkephalin decrease in the neurohypophysis are peptide specific.

The striking effect of dehydration on the (ir)-Leu-enkephalin content on the neurointermediate lobe led us to examine the distribution of enkephalin in the Brattleboro rat. In this strain the homozygous offspring are polyuric and totally unable to synthesise or secrete vasopressin[8]. When compared with unaffected heterozygote littermate controls, the (ir)-Leu^5-enkephalin levels (Table 2) in the neurointermediate lobe of Brattleboro rats are very low (33% of the heterozygous controls). No differences between homozygous and heterozygous Brattleboros were observed in the (ir)-Leu^5-enkephalin

Table 2 Opioid peptides in pituitary after dehydration

Rat strain	(ir)-β-endorphin ng per lobe (mean ± s.e.m.)		(ir)-Leu^5-enkephalin pg per lobe (mean ± s.e.m.)
	Anterior	Neuro-intermediate	Neuro-intermediate
Sprague-Dawley			
Controls (6)	375±46	661±66	880±60
5 d with 2% NaCl drinking fluid (6)	475±79	647±117	320±80†
Brattleboro			
Controls (*Di*/?) (4)	850±103	705±80	470±19
Polydypsic (*Di*/*Di*) (4)	1,205±98*	1,140±140*	156±26†

In two separate experiments, Sprague-Dawley male (200 g) rats which had received 2% NaCl as drinking fluid for 5 d were compared with their controls which had received plain tap water, and male (120 g) homozygous (*Di*/*Di*) Brattleboro rats were compared with their control littermates (*Di*/?). Radioimmunoassay for β-endorphin and Leu^5-enkephalin was carried out on 1 M acetic acid extracts as described in Fig. 1. Weights of the control Sprague-Dawley anterior and neurointermediate lobe were, respectively, 6.2±0.3 and 0.95±0.07 mg. The 2% NaCl animals had a statistically significantly ($P < 0.01$) decreased weight of their anterior lobe (4.2±0.4) and no statistically significant change in their neurointermediate lobe weight (0.80±0.04).

*$P < 0.05$; †$P < 0.01$, *t* test.

levels of hypothalamus or striatum. (ir)-β-endorphin was slightly elevated in the homozygous Brattleboro rats, both in the anterior and posterior lobes of the pituitary, but was unchanged in the hypothalamus. Immunocytochemical studies of the enkephalin fibres in the pars nervosa of the Brattleboro indicated that the number of enkephalin fibres here are decreased and their distribution and morphology somewhat dystrophic (Fig. 2*c*).

Morphine injections are known to release vasopressin into the bloodstream[11], and opiate receptors are also concentrated in the pars nervosa[12]. Therefore, we propose that these receptors are related to the enkephalinergic innervation of the pars nervosa. Furthermore, because dehydration decreased both the enkephalin and the vasopressin content of the pars nervosa, we propose that pituitary enkephalin fibres may have a role in the regulation of vasopressin or other magnocellular hormonal secretion.

The granulated peripolar epithelial cell: a potential secretory component of the renal juxtaglomerular complex

THE renal juxtaglomerular complex is conventionally considered to consist of the afferent and efferent glomerular arterioles, the macula densa of the distal tubule, and the interposed polar cushion region[1]. The afferent arteriolar wall contains myoepithelial cells characterised by the presence of multiple secretory-type cytoplasmic granules. It is widely accepted that such granules contain renin[2], the hormone responsible for the production of angiotensin I from plasma renin substrate. We now report the finding of another potential secretory component of the juxtaglomerular complex, raising the possibility of unsuspected functional interactions in this region.

During a study of the influence of salt-balance status on juxtaglomerular morphology in sheep, considerable difficulty was experienced in detecting arteriolar myoepithelial cell granules using Bowie's stain[3] or electron microscopy. However, sections through the vascular pole of many glomeruli revealed the presence of a new, distinctive type of cell which contains multiple cytoplasmic granules closely resembling those of the arteriolar myoepithelial cells. These new cells are in an epithelial position, encircling the origin or polar region of the glomerular tuft (Fig. 1). We have therefore called them 'peripolar cells'. They form junctional complexes with the parietal epithelium of Bowman's capsule on one side and visceral podocytic epithelium on the other; one surface is attached to the basement membrane of Bowman's capsule and the other is directly exposed to the urinary space. Up to four such peripolar cells have been observed surrounding the origin of any one glomerular tuft. The chief morphological characteristic of such cells is the presence of large numbers of closely packed cytoplasmic granules which react positively with methylene blue, the periodic acid-Schiff technique, Brilliant Crystal Scarlet (using Lendrum's Martius-Scarlet Blue stain[4] following fixation in Helly's fluid) and Bowie's stain. Electron microscopically, the granules are membrane-bound, mostly round in shape and contain homogeneous, finely fibrillo-granular electron-dense material (Fig. 2). Typically, most granules range from 100 to 500 nm in diameter. Although most granules in any one cell are of fairly uniform electron density, a few granules display a paler matrix. Granules at the cell periphery have occasionally been observed in the process of discharging their contents into the urinary space. The cytoplasm also contains mitochondria, prominent Golgi membranes, segments of rough endoplasmic reticulum, free ribosomes, and scattered microfilaments and microtubules.

Granulated peripolar cells are usually large in sheep, are sometimes prominent in man, but are less readily found and much smaller in rats and mice. It is most interesting that, thus far, prominent peripolar cells have been found in species with poorly developed afferent arteriolar granulation; in contrast, peripolar cells seem to be relatively smaller in species with abundant arteriolar granulation. The composition of the granules and their function await elucidation. In view of their topographical location, it is almost certain that they participate in juxtaglomerular complex activity. They are ideally situated to release factors directly into Bowman's capsular space, perhaps triggered by electrolyte changes in the glomerular ultrafiltrate, or by variations in afferent or efferent arteriolar calibre (leading to alterations in the diameter of the polar region of the glomerular tuft), or in response to diffusible mediators released from other components of the complex. Factors released from

peripolar cells could pass into the tubular fluid and be involved in the modulation of secretory or resorptive functions of tubular cells. There has been much study directed towards determining the factors controlling proximal tubular sodium reabsorption and glomerulotubular balance[5-7]. One school of thought holds that a previously unrecognised hormone is involved in these processes. It has recently been reported that proximal tubular fluid contains a factor which mediates increased volume reabsorption in the proximal tubule in response to increased glomerular filtration rate[8]; it was suggested that such increased volume reabsorption results from increased proximal tubular sodium reabsorption[8]. The proximal tubular fluid factor responsible for these effects was not present in an artificial ultrafiltrate of plasma[8], indicating that it is added to the tubular fluid after filtration of plasma across the glomerular capillary wall. It is possible that the peripolar cell is the source of such a factor, thereby having a key role in glomerulotubular balance and electrolyte homeostasis.

T-cell hybrids bear Fcγ receptors and secrete suppressor immunoglobulin binding factor

PROGRESS in the study of antibody structure and function came from the establishment of plasmocytomas and B-cell hybrids[1] which produce large amounts of monoclonal antibodies. Another set of immune molecules, the T-cell factors regulating antibody production[2], have not previously been extensively characterised, mainly because of the lack of homogenous and reproducible sources. The use of T-cell hybrids[3-5] which would produce large amounts of a given factor would therefore be very useful for the characterisation of these molecules. Among the T-cell factors regulating antibody production, Gisler and W.H.F.[6] have described an immunoglobulin binding factor (IBF) which binds to IgG, not to IgM and suppresses antibody production to T-dependent and T-independent antigens nonspecifically *in vitro*. IBF is the soluble form of the T-cell Fcγ receptor[7] which is expressed on non antigen-specific suppressor T cells[8,9]. As the Fcγ receptor is a marker of a set of suppressor T cells, one would expect that selection of T-cell hybrids for the expression of this receptor may lead to selection of T-cell lines producing permanently non antigen-specific suppressor factor. We report here the establishment of T-cell hybrids which express Fcγ receptors and produce suppressor IBF.

T1 hybrid cell line and clones were obtained by fusion of BW 5147 T lymphoma cells (hypoxanthine, aminopterin and thymidine (HAT) sensitive, $H\text{-}2^k$ Thy-1.1 positive, Fcγ receptor negative) with spleen cells from C57BL/6 ($H\text{-}2^b$) mice primed with sheep red blood cells (SRBC). The T2C2 and T2D4 cell lines were obtained by fusion of the BW 5147 T lymphoma cells with B10.BR alloantigen-activated T cells ($H\text{-}2^k$, Thy-1.2 positive and 40% Fcγ receptor positive). Cells were fused using polyethylene glycol (PEG) as a fusion agent (Table 1). After distribution in microplates and two weeks of selection in HAT medium, hybrid populations were grown in RPMI 1640 medium (Eurobio) containing 10% fetal calf serum (FCS) (Eurobio) (RPMI FCS). The hybrids were selected for the presence of membrane Fcγ receptors by a rosette technique and tested for the expression of H-2, Thy-1 and Lyt alloantigens by microcytotoxicity assays. Rosette determinations were carried out at 4 °C using sheep erythrocytes (E) sensitised with IgG (EAIgG) or IgM (EAIgM) rabbit anti-Forssman antibodies[7]. The clones

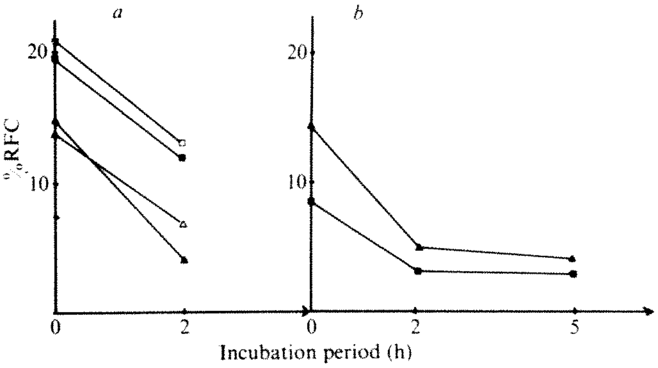

Fig. 1 Release of Fc receptors from T-cell hybrids. Hybrid cells were incubated from 2–5 h at 37 °C at a concentration of 2×10^6 cells per ml and tested for their capacity to form rosettes with EAIgG. Rosette determinations were performed at 4°C by mixing 5×10^5 hybrid cells with 10^7 IgG-sensitised erythrocytes in 0.5 ml BSS. After centrifugation at 1,000 r.p.m. for 10 min at 4°C, and gentle resuspension, rosettes were counted. *a*, □, T_1C1E_9; ■, T1; ▲ T1ClE5; △ T1ClE4; *b*, ▲, T2C2; ■ T2D4. Table 1 Karyotic analysis and cell surface markers of T-cell hybrid lines

Hybrid cell lines*	Parental populations†		Average no. of chromosomes‡	Cell surface markers§
T1	AKR T lymphoma BW5147 ($H-2^k$, Thy-1,1)	× Spleen cells from C57BL/6 mice immunised with SRBC ($H-2^b$, Thy-1.2, Lyt-1.2, Lyt-3.2)	53	$H-2^b$, $H-2^k$, Thy-1,2, Thy-1,1, Lyt-3,2
T2C2 and T2D4	AKR T lymphoma BW5147	× B10.BR *in vivo* alloantigen-activated T cells ($H-2^k$, Thy-1.2)	51	$H-2^k$, Thy-1.1, Thy-1.2

* Fusion was performed by adding 1 ml of 50% PEG (w/v) 1500 in serum-free RPMI to a pellet of a mixture of 10^8 spleen cells and 10^7 BW5147 cells[3]. After 1 min at 37°C, the suspension was gradually diluted to 10 ml (in 5 min) with serum-free RPMI 1640. After centrifugation RPMI FCS was added and cell suspension was distributed in 0.2 ml microplates (Falcon no. 3040) at a concentration of 2×10^6 cells per well and grown in selective HAT medium in a CO_2 incubator (5% CO_2) in air). Two weeks later, selective medium was removed and replaced by RPMI FCS.

† Spleen cells of C57BL/6 mice were collected 5 days after immunisation by intraperitoneal injection of 10^8 SRBC. Alloantigen-activated B10.BR T cells were taken from spleens of lethally irradiated (850 rad) BALB/c mice reconstituted 5 d before by intraveneous injection of 10^8 B10.BR thymocytes.

‡ The average number of chromosomes of BW5147 was 43. In each experiment 15 to 21 mitoses were observed.

§ The hybrid cell lines were negative for cell surface Ig as revealed by immunofluorescence. The detection of other cell surface markers was performed by a microcytoxicity technique using guinea pig serum as a source of complement. 100% cells of T1 hybridoma were killed by C3H anti-C57BL/6 (anti-$H-2^b$) antiserum up to 1/80 dilution, by C57BL/6 anti-C3H (anti-$H-2^k$) antiserum up to 1/160 dilution, by AKR anti-C3H (anti-Thy-1.2) antiserum up to 1/40 dilution, by C3H anti-AKR (anti-Thy-1.1) antiserum up to 1/20 dilution and by C58 anti-C58.CE Lyt-3.2 (anti-Lyt-3.2) antiserum up to 1/20 dilution. It was resistant to lysis by C3H anti-C3H.CE Lyt-1.2 (anti-Lyt-1.2) antiserum. 100% cells of T2C2 and T2D4 were killed by C57 anti-C3H (anti-$H-3^k$) antiserum up to 1/160 dilution, by C3H anti-AKR (anti-Thy-1.1) antiserum up to 1/20 dilution, and by AKR anti-C3H (anti-Thy-1.2) antiserum up to 1/20 dilution.

T1ClC5, T1ClE4 and T1ClE9 from the Fcγ receptor-positive T1 hybrid were obtained by distribution of individual cells in microplates and were grown in RPMI FCS.

In a first series of experiments we established that T1 and T2 are T-cell hybrids. As shown in Table 1, their number of chromosomes (50–54) is higher than the number of chromosomes of the BW 5147 lymphoma (41–45), and they express H-2 and Thy-1 alloantigens of both parental strains and no cell surface immunoglobulins. In addition, T1 hybrid cells were found to be positive for Lyt-3.2 antigen which is known to be a marker of cytotoxic and suppressor T cells and to be negative for Lyt-1.2 antigen. With regard to the presence of Fcγ receptors, T1 hybrid, its clone derivatives (T1ClC5, T1ClE4, T1ClE9) and the several T2 hybrid populations (T2C2, T2D4 and five others) showed a permanent (over 12 months) capacity to form rosettes with EAIgG, while the parental BW cell line was negative. These rosettes detect specifically the Fcγ receptors as: (1) 100% are inhibited by aggregated rabbit and mouse IgG and not by aggregated $F(ab')_2$ fragments of rabbit IgG or by mouse IgM; and (2) no rosettes were found with E or EAIgM (data not shown).

In previous studies we have shown that, when activated T cells are incubated at 37 °C, the Fcγ receptors disappear from the cell surface and suppressor IBF appears in the supernatant[10]. We therefore tested whether hybridomas would exhibit a similar phenomenon. When taken from the cultures and washed, 6–35% of cells of the different hybrid cell lines could form EAIgG rosettes depending on the phase of the culture. As shown in Fig. 1, after incubation of the hybrid cells for 2–5 h at 37°C at a concentration of 2×10^6 cells per ml in serum-free BSS, the number of EAIgG rosette-forming cells (EARFC) was much decreased. This was not due to death of Fcγ receptor-positive cells as viability remains constant throughout the incubation period, but rather suggests that the hybrid cell lines, like the activated T cells[7], may release Fcγ receptors into the medium. To determine if suppressor IBF is produced by the hybrid cells in these conditions, supernatants of 2×10^6 cells incubated for 2 h at 37 °C in serum-free BSS were tested for the presence of a suppressor factor which could be retained on IgG immunoadsorbents. Table 2 shows representative experiments. In most cases, crude supernatants of the hybrid cell lines (T1ClC5, T1ClE4, T1ClE9, T2C2 and T2D4) suppressed *in vitro* antibody production to SRBC and this suppressive activity was recovered in the acid eluates of IgG immunoadsorbents but not in the effluents. In one case (T1), even if no suppressive activity could be found in the crude supernatant, the acid eluate and not the effluent strongly inhibited the PFC response. As a control, neither the crude supernatants nor their acid eluates of BW 5147 parental cell line exerted suppressive activity. As the acid eluates contain only molecules which bind to IgG—IBF by definition—and the effluents are specifically devoid of these molecules, it is possible to state that the Fcγ receptor-positive T-cell hybrids produce suppressor IBF.

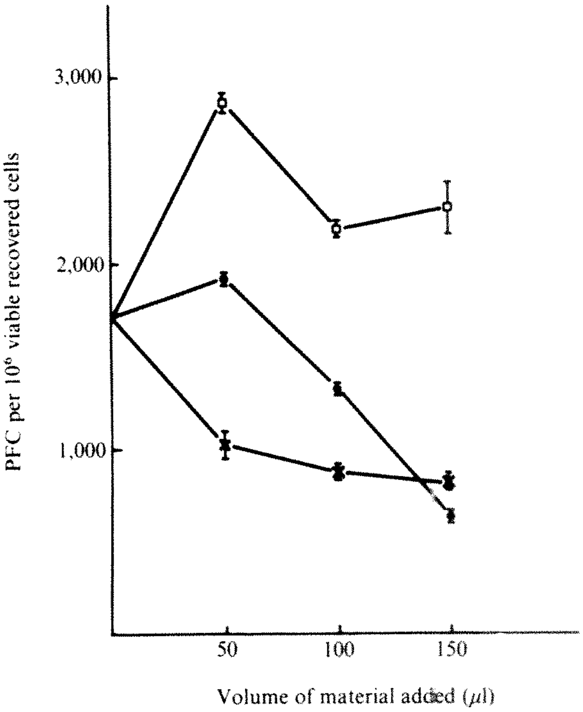

Fig. 2 Titration of suppressive IBF produced by T1 hybrid cells. Graded doses of crude supernatants (●), effluents (□) and acid eluates (×) from IgG immunoadsorbents were added 48 h after antigen to spleen cell cultures of C57BL/6 mice stimulated by SRBC, using a technique in tubes[6]. Direct PFC were measured at day 5 by the local haemolysis technique in liquid medium[11]. Each culture was made in duplicate and results are expressed as PFC per 10^6 viable recovered cells.

The amount of suppressor factor produced by the hybrids is similar to the amount of suppressive IBF produced by activated T cells, as when supernatants and acid eluates from activated T cells or hybrid cells were prepared in the same way and tested at the same dose, no significant differences could be detected (Table 2). To titrate the suppressor factor produced by hybrid cells more precisely, graded doses of supernatants, effluents and acid eluates from IgG immunoadsorbents were added to spleen cells stimulated with SRBC. Figure 2 shows a representative experiment using T1 hybrid. A dose-dependent inhibition of antibody production was obtained with supernatant and acid eluate, while no suppression was observed with the effluents. Similarly to T-cell-produced IBF[6], 100% inhibition was never found, but 60–70% were obtained with small doses of acid eluate and high doses of crude supernatant, indicating enrichment in suppressive activity. The binding of suppressor factor

* 8×10^6 spleen cells from B6D2F1 mice were cultured in RPMI 1640 supplemented with 10% FCS (Rehatuin–Rehcis), 1% horse serum and antibiotics (penicillin, streptomycin) in Falcon plastic tubes for 5 d in a CO_2 incubator (5% CO_2 in air)[6]. SRBC (3×10^6 cells) were added at day 0, 100 μl of materials were added 48 h later and direct PFC were enumerated at day 5 by the liquid local haemolysis technique[11]. PFC are expressed per 10^6 viable recovered cells.

† Hybrid cells or activated T cells were washed at 4 °C in BSS and incubated at a concentration of 2×10^6 cells ml^{-1} for 2 h at 37 °C in serum-free BSS. Cell-free supernatants were taken after centrifugation at 200*g* for 10 min.

‡ Cyanogen bromide-activated Sepharose beads (Pharmacia) were coupled with 5 mg ml^{-1} of rabbit IgG (Miles, Eurobio) in sodium bicarbonate buffer, 0.1 M *p*H 8 (ref. 12). For immunoadsorption, a batch technique was used: 2 volumes of supernatants were mixed with 1 volume of Sepharose beads for 2 h at 22 °C, and the effluents were recovered after centrifugation. After washings in phosphate buffer, 0.02 M *p*H 7, the beads were incubated in 0.2 M glycine HCl *p*H 2.8 buffer and the eluates were recovered by centrifugation and neutralised to *p*H 7. Effluents and eluates were concentrated to half starting volume, dialysed against BSS, and sterilised on 0.22 μm Millipore filter.

‖ Alloantigen-activated T cells were prepared as described in legend to Table 1.

ND, Not determined. % In, % inhibition. Thirty per cent inhibition was considered significant.

specifically to IgG and its non-antigen specificity is shown in Table 3. First, in experiment 1, crude supernatant of the T1 hybrid cell line inhibits 21% of the plaque-forming cell (PFC) response, and all the suppressive activity is present in the acid eluate of an IgG immunoadsorbent and not in the effluent. By contrast, when the same supernatant is applied to an IgM immunoadsorbent, suppressive activity is recovered in the effluent and not in the eluate, indicating that the suppressor factor binds specifically to IgG. As T1 hybrid was prepared with spleen cells sensitised with SRBC, it was necessary to rule out the presence of an antigen-specific suppressor factor in the eluates. Experiment 2 in Table 3 shows that the suppressive activity found in acid eluates from IgG immunoadsorbents could not be adsorbed on SRBC, demonstrating that IBF produced by T-cell hybrids as well as IBF produced by activated T cells behave as a non-antigen-specific suppressor factor.

T-cell hybrids have already been obtained by several laboratories[1–5] but in most cases, except for one hybrid producing an antigen-specific suppressor factor[13], immunological functions of parental spleen cells were lost after fusion. A recent report by Taniguchi and Miller[14] describes several T-cell hybridomas obtained by using parental spleen cells enriched for I-J subregion markers and containing specific and nonspecific suppressor factors. However, suppressive activity was lost after 3 months of culture. The present work shows that selection of T-cell hybrids for the presence of Fcγ receptors leads to the establishment of lines which produce permanently (over 12 months) non-antigen-specific suppressor factor. Also, some T lymphomas have been shown to permanently produce immunoregulatory molecules[15] and in particular, Fc receptors[16,17]. However, first, these molecules are of tumour and not T-cell origin and may not be identical to physiological products, and second, hybridisation of a given lymphoma with selected T-cell subpopulations may lead to T-cell lines producing various factors which could be compared on a biochemical basis and whose eventual differences could not be due to different origin of the tumour cells. These T-cell lines may be very useful for the characterisation of factors and for *in vivo* studies.

Novel α_2-adrenoreceptors primarily responsible for inducing human platelet aggregation

BLOOD PLATELETS isolated from humans, in contrast to those from other mammalian species, aggregate on exposure to adrenaline or noradrenaline[1]. Studies using α antagonists have shown that this effect results from occupancy of an α adrenoreceptor[2,3]. However, Jakobs has reported that selective α agonists such as clonidine and phenylephrine bind with high affinity to the platelet α adrenoreceptor[4,5], but fail either to induce an aggregation response[6] or to inhibit platelet adenylate cyclase[6], in contrast to the effects of natural agonists such as adrenaline[1,7]. Instead, such α agonists seem to act as antagonists at the platelet adrenoreceptor[6]. α Adrenoreceptors in other tissues have been classified as α_1 (postsynaptic) or α_2 (presynaptic) on the basis of their affinities for various selective α agonists and antagonists[8]. Jakobs[6] has, however, interpreted his data on the human platelet adrenoreceptor as indicating the existence of a third category of α adrenoreceptor at which only the natural catecholamines are agonists. We report here that we have confirmed the observation that clonidine and phenylephrine are ineffective in inducing aggregation of human platelets and act as inhibitors of the response to adrenaline. However, further examination has revealed that the effects of these selective α agonists differ in certain important respects from those of selective α antagonists, thus requiring substantial modification of the thesis advanced by Jakobs[6].

Figure 1 shows the effect of clonidine and of yohimbine, a selective α_2 antagonist[9,10], on the aggregation response of human platelets to ADP, vasopressin and serotonin. Addition of clonidine 15 s before each of these agonists causes marked stimulation of both phases of the response. Stimulation of the response is also observed if clonidine is added before other agonists, such as collagen, thrombin or arachidonate. From the detailed dose–response curve (Fig. 1*a*) the concentration of clonidine which gives half-maximal stimulation of aggregation induced by ADP is 0.6 μM, in agreement with the concentration of this selective α agonist which gives half-maximal inhibition of the primary response to adrenaline (0.6 μM). In contrast, yohimbine, which is also an effective inhibitor of aggregation induced by adrenaline (Fig. 2*a*), has little effect on aggregation induced by most other agonists (compare Fig. 1*b* and *c*) at concentrations which completely inhibit the response to adrenaline, and notably fails to stimulate these responses. The only exception is the response to serotonin where the extent of inhibition by yohimbine is rather more marked (Fig. 1*d*). However, yohimbine is an effective inhibitor of the stimulation by clonidine of the response to other agonists (such as ADP, vasopressin, serotonin)(Fig. 1*b–d*). The concentration of yohimbine required for half-maximal inhibition of stimulation by clonidine of the response to ADP (2.5 μM) is, however, significantly greater than that which causes half-maximal inhibition of the primary phase of the response to adrenaline (0.5 μM).

Similar studies have been carried out using phenylephrine and the selective α_1 antagonist, indoramin[12,13]. Phenylephrine added 15 s before platelet agonists other than adrenaline also

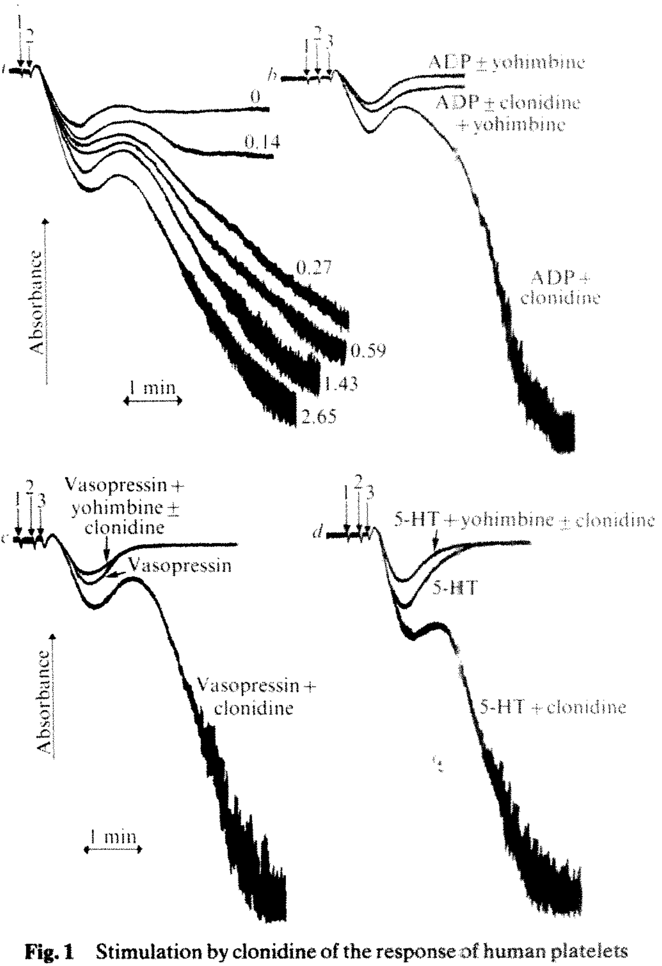

Fig. 1 Stimulation by clonidine of the response of human platelets to ADP, vasopressin and serotonin (5-HT) and the inhibition of this effect by yohimbine. Platelet-rich plasma was obtained from drug-free donors using 0.1 volumes of acid-citrate dextrose (0.1 M citrate) as anticoagulant, and platelet aggregation was monitored using a Payton dual-channel aggregometer as described previously[11]. Additions were as folllows: *a*, at 1, clonidine at the concentrations (μM) indicated by the numbers on the traces; at 2, 1.25 μM ADP; *b*, at 1 when indicated, 5 μM yohimbine, at 2 when indicated, 5.7 μM clonidine, at 3, 0.75 μM ADP; *c*, at 1 when indicated, 10 μM yohimbine, at 2 when indicated, 5.7 μM clonidine, at 3, 0.046 nM vasopressin; *d*, at 1 when indicated 10 μM yohimbine, at 2 when indicated, 5.7 μM clonidine, at 3, 1 μM serotonin. Absorbance is in arbitrary units.

causes a stimulation of the response to these agonists which is similar in magnitude to that observed in the presence of clonidine (Fig. 1). This is shown in Fig. 3 for ADP, thrombin and arachidonate. The concentration of phenylephrine which gives half-maximal stimulation of the response to ADP (30 μM)(Fig. 3*a*) is in reasonable agreement with that which gives half-maximal inhibition of the response to adrenaline (25 μM), although we did not obtain complete inhibition of the adrenaline response by phenylephrine at concentrations where the effect is specific. In contrast, indoramin fails to stimulate the response of human platelets to ADP or thrombin over a range of concentrations which causes inhibition of the response to adrenaline (Fig. 3*b*, *c*). The concentration of indoramin required to cause 50% maximal inhibition of the adrenaline response is 42 μM (Fig. 2*b*). Although 150 μM indoramin causes complete inhibition of the response to adrenaline the effect may represent a nonspecific action, as this concentration also causes complete inhibition of the response to ADP. Specific inhibition of the adrenaline response is only observed at indoramin concentrations <50 μM. Both yohimbine and indoramin selectively inhibit phenylephrine stimulation of the response to ADP (Fig. 3*b*), The concentrations of these antagonists required to give half-maximal inhibition of the stimulated response are 27 and 2 μM, respectively. Indoramin also selectively blocks phenylephrine-induced stimulation of the response to thrombin (Fig. 3*c*).

The stimulation of the response of human platelets to agonists such as ADP, vasopressin, serotonin and thrombin which results from the addition of the specific α agonists (Figs 1, 3) resembles that reported previously for rat platelets in which phenylephrine was found to enhance the response to ADP[14]. The effect in human platelets is quantitatively similar to that observed when a non-aggregating concentration of adrenaline is added before any one of these agonists[2,15]. As selective α antagonists fail to stimulate the response of human platelets to agonists other than adrenaline but act as inhibitors with respect to adrenaline itself, selective α agonists such as clonidine and phenylephrine seem to interact as partial agonists at the platelet adrenoreceptor rather than as antagonists as suggested by Jakobs[6]. This situation, although unusual, is not unique, as other systems have been described in which clonidine at least, seems to act as a partial agonist[16].

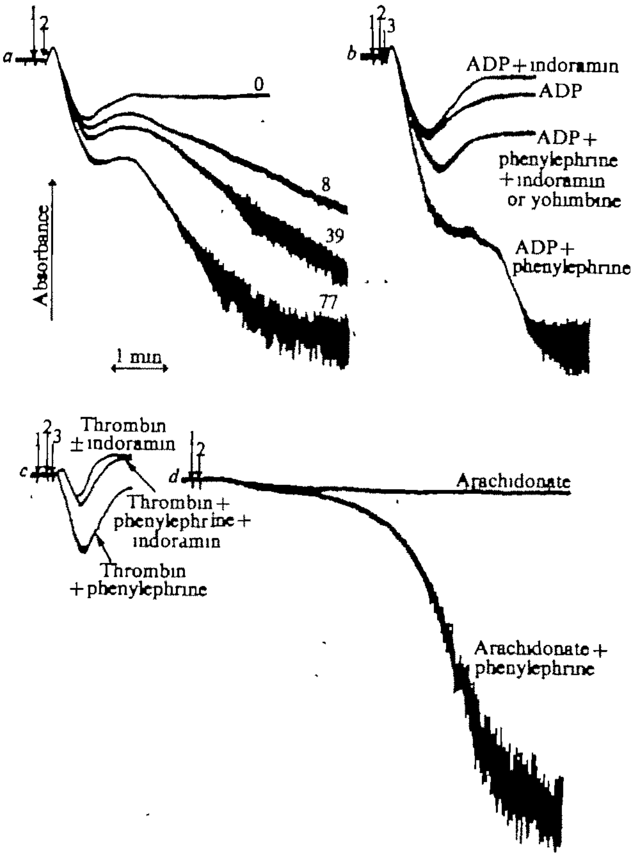

Fig. 3 Stimulation by phenylephrine of the response of human platelets to ADP, thrombin and arachidonate and the inhibition of this effect by yohimbine and indoramin. Platelet aggregation was monitored as described for Fig. 1. Additions were as follows: *a*, at 1, phenylephrine at the concentrations (μM) indicated by the numbers on the traces; at 2, 1.25 μM ADP, *b*, at 1 when indicated, 10 μM indoramin or 40 μM yohimbine, at 2 when indicated, 77 μM phenylephrine and at 3, 1.5 μM ADP; *c*, at 1 when indicated, 5 μM indoramin, at 2 when indicated, 77 μM phenylephrine, at 3, 0.28 units thrombin; *d*, at 1 when indicated, 38.5 μM phenylephrine; at 2, 0 4 μM arachidonate.

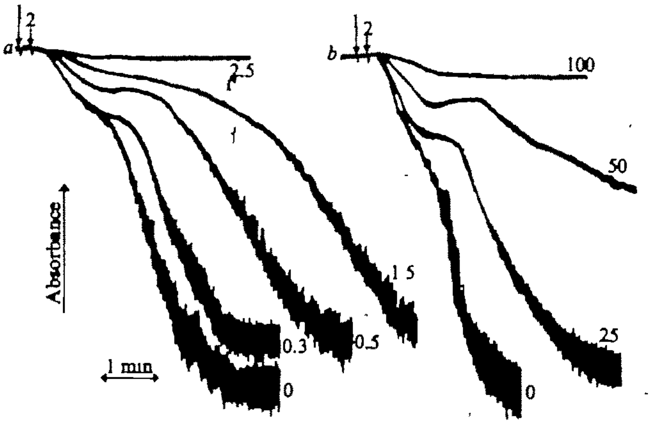

Fig. 2 Inhibition by yohimbine and indoramin of the response of human platelets to adrenaline. Platelet aggregation was monitored as described for Fig. 1. Additions were as follows: *a*, at 1, yohimbine at the concentrations (μM) indicated by the numbers on the traces, at 2, 5 μM adrenaline; *b*, at 1, indoramin at the concentrations (μM) indicated by the numbers on the traces; at 2, 5 μM adrenaline.

Our data also provide insight into the nature of the adrenoreceptors on human platelets that are responsible for initiation of the aggregation response. As yohimbine is two orders of magnitude more potent than indoramin as an antagonist of aggregation induced by adrenaline (Fig. 2), this latter response seems to be mediated by α_2 adrenoceptors. A similar conclusion is applicable to the action of clonidine as a partial agonist in stimulating the response to agonists other than adrenaline, although in this case, blockade by yohimbine occurs over a range of concentration significantly higher than that required for inhibition of the response to adrenaline (Figs 1, 2). In contrast, indoramin at concentrations <50 μM has little effect as an inhibitor of the clonidine-stimulated responses, as would be expected from the relative efficiency of the two antagonists on the response to adrenaline (Fig. 2). However, the pattern of inhibition by indoramin and yohimbine is exactly reversed for phenylephrine stimulation of the response to agonists other than adrenaline: In this case, complete blockade of the stimulated response by indoramin occurs at a concentration (5–10 μM) which has little, if any, effect on aggregation induced by adrenaline (Figs 2*b*, 3*b*, *c*). Blockade by yohimbine of the phenylephrine stimulation is, in contrast, less effective than that caused by indoramin and occurs only at concentrations of yohimbine well in excess of those required for inhibition of the responses to adrenaline or clonidine. This pattern of inhibition suggests that, in contrast to adrenaline or clonidine, phenylephrine is exerting its effects through α_1 adrenoreceptors which are, however, less effective in inducing aggregation and make only a minor contribution to the response to the natural agonist.

Both our data and those of Jakobs[6] seem, therefore, to be satisfied by a postulate which suggests that human platelets carry both α_1 and α_2 adrenoreceptors at which phenylephrine and clonidine, respectively, act as partial agonists. The α_2 adrenoreceptor is identified as being primarily responsible for mediating the response to the natural agonist. This conclusion seems to agree with the nature of the response of human platelets to adrenaline that involves secretion as well as aggregation[2,8]. The proposal by Jakobs[6] that the platelet carries a unique species of adrenoreceptor does not seem warranted by the data now available.

We thank Dr Stewart Johnson for gifts of clonidine and indoramin.

Amines inhibit the clustering of α_2-macroglobulin and EGF on the fibroblast cell surface

α_2-MACROGLOBULIN (α_2M), insulin and epidermal growth factor (EGF) have a common mechanism for internalisation[1]. We have proposed a model for this mechanism[1-3] in which the ligands bind to diffusely distributed receptors followed by the collection of the mobile ligand–receptor complexes over coated pits. These coated pits pinch off from the plasma membrane to form endocytic vesicles. The diffuse initial distribution of the α_2M receptors has been shown by binding α_2M to fixed cells and observing the location of α_2M by an electron microscopic immunocytochemical method[2]. The mobility of the ligand–receptor complexes has been demonstrated using fluorescence photobleaching recovery[4], and the clustering of such complexes has been demonstrated by fluorescence microscopy[1,3,5]. Electron microscopic immunocytochemical localisation has been used to show that the clustering occurs over coated pits which pinch off to form endocytic vesicles[2]. The mechanism proposed for the endocytosis of α_2M, insulin and EGF is similar to that described for the internalisation of low density lipoprotein (LDL), except that unoccupied LDL receptors may cluster in coated pits before binding LDL[6]. It seems likely that many molecules, including other polypeptide hormones and the lysosomal hydrolases[7] which bind to specific receptors on the cell surface, are internalised by a similar mechanism. To determine the role of clustering and internalisation in hormone action it would be useful to have an agent that inhibits these processes. It has been found that the internalisation of lysosomal enzymes is noncompetitively inhibited by some amines and ammonia (E. Neufeld, personal communication). It has also been reported that ammonia prevents the internalisation of diptheria toxin by HeLa cells[8]. In view of these effects, we examined the possibility that amines and ammonia would block the clustering of α_2M and EGF, and we report here that these agents are effective in blocking clustering and internalisation.

When rhodamine-labelled α_2-macroglobulin (R-α_2M) is added to the culture medium of Swiss 3T3-4 cells, the fluorescent emission from the R-α_2M is observed in a punctate distribution on the cells[5] (Fig. 1*a*) as a result of clustering and endocytosis[1,2]. In contrast to the punctate fluorescence seen in Fig. 1*a*, R-α_2M added after a brief incubation with methylamine forms a diffuse pattern of fluorescence on the cells (Fig. 1*b*). No inhibition of clustering was noted at amine concentrations below 0.1 mM, and the inhibition of clustering is complete at 10–30 mM methylamine hydrochloride.

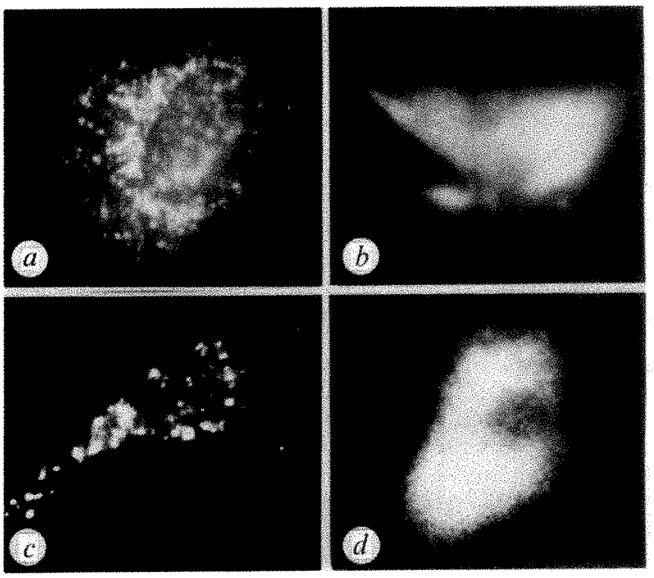

Fig. 1 Inhibition of α_2M clustering. *a*, Swiss 3T3-4 cells were incubated for 20 min at 37 °C in Dulbecco–Vogt's modified Eagle's medium containing 30 μg ml^{-1} R-α_2M. *b*, Cells were incubated with 10 mM methylamine hydrochloride for 20 min at 37 °C and 30 μg ml^{-1} R-α_2M was then added for a further 20 min incubation at 37 °C. In *c*, 30 mM methylamine was present before and during the 20 min incubation with R-α_2M. The cells were then rinsed with fresh medium and incubated for 20 min at 37 °C. This resulted in a punctate fluorescence pattern similar to that in *a*. When methylamine was present for the final incubation (not shown), the fluorescence remained diffuse as in *b*. *d*, Cells were incubated in medium without Ca^{2+}, containing 1 mM Mg^{2+} and 1 mM EGTA, for 5 min at 37 °C. 30 μg ml^{-1} R-α_2M was then added, and the cells were incubated for 30 min at 37 °C. After the indicated incubations, the cells were rinsed and fixed with 2% formaldehyde in Dulbecco's phosphate-buffered saline for 1 min at 23 °C. The fluorescence was recorded on videotape using a silicon intensifier target television camera[5], and photographs were taken from the video monitor. Magnification, ×678.

Ammonium acetate and the hydrochloride salts of methylamine, ethylamine, propylamine and *n*-butylamine were all effective in blocking clustering, and all showed a similar concentration dependence. *t*-Butylamine was slightly less effective than these amines in blocking clustering. Chloroquine (0.1 mM), lidocaine (1 mM), Tris-HCl (30 mM), *N*-acetyl-L-lysine-*N*′-methylamide (10 mM) and 1,4-diaminobutane-2HCl (putrescine) (10 mM) did not block clustering. It is apparently necessary for the amines to be inside the cells for the clustering to be inhibited, as simultaneous addition of methylamine and R-α_2M resulted in extensive clustering. The failure of putrescine to block clustering is probably due to its low rate of uptake[9], compared to aliphatic monoamines, which diffuse through the membrane as the uncharged species.

The fluorescence intensity of cells incubated with R-α_2M in the presence or absence of methylamine was approximately the same, indicating that the binding of α_2M by surface receptors is not blocked by the amine. Furthermore, R-α_2M which was bound diffusely to the cells in the presence of methylamine appeared in a punctate distribution 20 min after removing the amine from the medium (Fig. 1*c*). Fluorescence photobleaching recovery measurements[4,10] (F.R.M., unpublished) demonstrated that amines did not reduce the mobility of α_2M–receptor complexes.

0028–0836/79/0277—0661$01.00

The inhibition of clustering by methylamine was confirmed using immunocytochemical localisation. Figure 2*a* demonstrates the diffuse labelling of the plasma membrane. There was an occasional slight concentration of label in these conditions in a coated pit, but this degree of clustering is considerably less than that seen in the absence of methylamine (Fig. 2*b*). The morphology of the cells was not changed in any obvious way by methylamine treatment.

Removal of Ca^{2+} from the medium was also found to inhibit the clustering of R-α_2M (Fig. 1*d*). The R-α_2M bound to the cells in the absence of extracellular Ca^{2+} did not form clusters when fresh medium containing Ca^{2+} (without R-α_2M) was added to the cells. However, the cells were still able to form clusters after EGTA treatment; R-α_2M added with fresh Ca^{2+}-containing medium formed clusters normally. EGTA itself was not responsible for the inhibition of clustering. When excess (4 mM) Ca^{2+} was added to medium containing 1 mM EGTA, R-α_2M formed clusters on the cells. Magnesium was not able to substitute for calcium. Evidently, calcium must be present as the α_2M binds to its cell surface receptor, as addition of calcium after removal of the R-α_2M from the medium did not result in clustering.

EGF has previously been shown to form clusters which coincide with the clusters formed by α_2M[1,3]. Figure 3 shows that 30 mM methylamine blocks the clustering of a rhodamine-labelled derivative of EGF. As with α_2M, binding to cell surface receptors was not inhibited by methylamine.

It has been suggested that ammonia, chloroquine and lidocaine might block the degradation of EGF by the same mechanism, perhaps by inhibition of proteolysis in lysosomes[11]. Our results indicate that the proximal effect of ammonia (but not chloroquine or lidocaine) in blocking EGF degradation is the inhibition of clustering. Ammonia also blocks the degradation of human choriogonadotropin (HCG) by murine Leydig tumour cells, without affecting HCG-induced steroidogenesis[12]. We speculate that the internalisation of this hormone is blocked by ammonia.

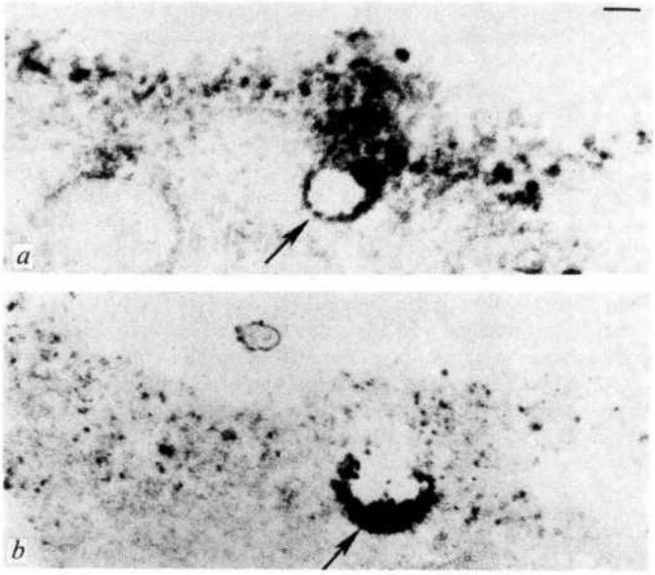

Fig. 2 Localisation of surface-bound α_2M. Cells were pretreated with 30 mM methylamine (*a*) for 20 min at 37 °C followed by incubation with 250 μg ml^{-1} α_2M for 5 min. They were then rinsed and fixed with 2% glutaraldehyde, and the surface-bound α_2M was detected using affinity-purified antibody to α_2M and peroxidase-conjugated anti-IgG (Cappel). Cells were incubated with diaminobenzidine substrate, post-fixed in 1.5% OsO_4, dehydrated in ethanol and embedded in Epon 812 as previously described[2]. Tangential thin sections were viewed without staining at 50 kV with a Hitachi HU-12A electron microscope. In *a* the diffuse labelling of the surface in 30 mM methylamine is shown, and a coated pit (arrows) shows little or no concentration of label above the rest of the surface. This is in marked contrast to the massive concentration of label in the coated pits in the absence of methylamine (*b*). Magnification, ×50,400; bar, 0.1 μm.

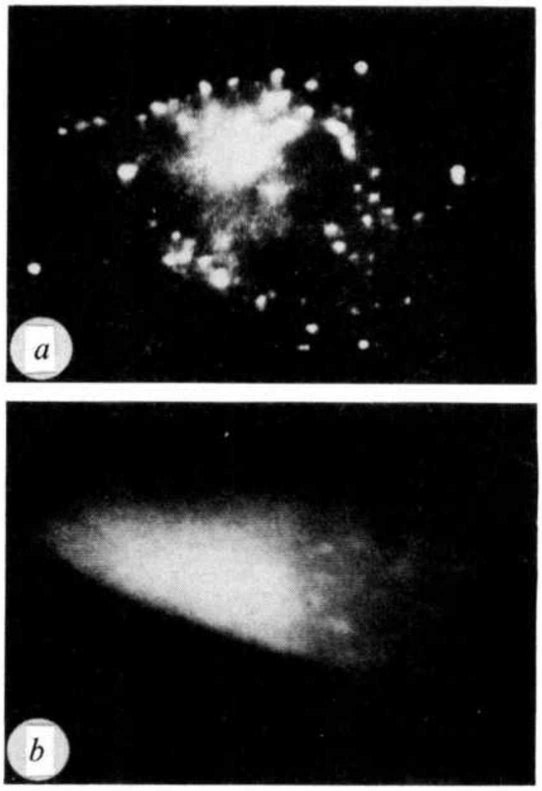

Fig. 3 Methylamine inhibition of EGF clustering. Cells were incubated in medium containing 1% fetal calf serum without (*a*) or with (*b*) 30 mM methylamine for 20 min at 37 °C. 50 ng ml^{-1} of rhodamine-labelled EGF was then added to the cells, and the cells were incubated for 20 min at 37 °C. They were then rinsed and fixed, and fluorescence was recorded as in Fig. 1. The rhodamine-labelled EGF consisted of rhodamine-labelled α-lactalbumin coupled to the α-amino group of EGF. The binding affinity of this derivative was shown to be the same as that of native EGF[16]. Magnification, ×1,130.

The mechanism for blocking clustering is not clear. One possible mechanism of action for the amines would involve an increase in the intracellular *p*H resulting from diffusion of uncharged amines across the plasma membrane followed by protonation inside the cell. It has been shown that chloroquine, methylamine and ammonia raise the lysosomal *p*H in this way[13]. The increase in *p*H could then, for example, interfere with a protein–protein interaction necessary for clustering.

An alternative is that the enzyme tranglutaminase is involved in the formation of clusters of receptor–ligand complexes over coated pits. This enzyme catalyses the formation of ε-(γ-glutamyl) lysine crosslinks between proteins[14]. It requires calcium for activity and is inhibited by ammonia and aliphatic amines, both of which are properties shared by the mechanism for the clustering of receptor–ligand complexes. ε-(γ-glutamyl) lysine crosslinks have been found in high concentrations in the plasma membrane proteins of mouse L cells[15]. According to this hypothesis, the binding of a ligand to its receptor would activate endogenous transglutaminase (through Ca^{2+} binding to the enzyme), which would then crosslink the receptor (or an associated protein) into the coated pit.

The inhibition of clustering by amines should prove useful in understanding the role of clustering and internalisation in various cellular functions. Hormone actions which require internalisation should be blocked by amines, and actions which occur only as a result of surface binding should be unaffected or enhanced. Further studies of the amine inhibition of clustering should help to elucidate the molecular mechanism for the clustering of ligand–receptor complexes.

We thank Ms Maria Gallo for preparing α_2M and affinity-purified antibody to α_2M and Ms Susan Yamada for technical assistance in preparing specimens for electron microscopy. Rhodamine-labelled EGF was supplied by Y. Shechter and J. Schlessinger.

Peptide map analyses of murine Ia antigens of the I–E subregion using HPLC

THE I REGION of the major histocompatibility complex (H-2) of the mouse[1] controls various immunologically related functions including immune responsiveness and T-cell, B-cell and macrophage interactions[2,3]. The only gene products of the I region which have been identified by immunochemical techniques are the Ia antigens which are encoded by loci mapping to the I-A and I-E subregions of the I region[4]. Previously there has been ambiguity over whether the I-E and/or I-C subregion(s) control molecules detected by immunoprecipitation. Recent evidence suggests that the former, not the latter, controls these molecules[5,6]. The Ia antigens are highly polymorphic by serological analysis and are expressed predominantly on B lymphocytes and epidermal cells[7]. Ia molecules are integral cell-surface glycoproteins and consist of two subunits of approximate molecular weights 35,000 (α) and 28,000 (β) which are noncovalently associated[7]. A general nomenclature has been agreed upon for the Ia polypeptides[8]. For example, the α polypeptide from the I–E subregion of a mouse of the H-2^d haplotype is denoted E^d_α. Partial N-terminal amino acid sequence analyses of Ia polypeptides from the I–E and I–A subregions of mice[8–14], humans[14,15] and guinea pigs[16] have led to several important observations. (1) The E_α polypeptides of mice show striking homology with human α chains (p34) at least at their N-termini. The E_β polypeptides of mice also demonstrate some homology with their guinea pig and human counterparts. (2) The Ia polypeptides from the I–A subregion of mouse show little apparent homology with their human, guinea pig and I–E-subregion counterparts. (3) The A_α, A_β and E_β polypeptides of various haplotypes differ by one or more residues at their N-termini. However, for the E^d_α and E^k_α polypeptides no amino acid differences have been unequivocally demonstrated. To determine whether the N-terminal differences in the E_β polypeptides extend throughout other regions of these polypeptides and whether the E_α polypeptides are identical, we have undertaken tryptic peptide analyses of two Ia molecules from the I–E subregion. We report here the application of high-pressure liquid chromatography (HPLC) to the separation of tryptic peptides and present comparative tryptic peptide maps for I–E subregion products from the H–2^d and H–2^k haplotypes.

Table 1 Genetic constitution of recipient–donor–target strain combinations of mice used to prepare alloantisera and Ia polypeptides

Strain		Haplotype	Regions of H-2 K	I A	 B	 J	 E	 C	 S	 D

(B10×HTT)F$_1$	(Recipient)	b/l	b	b	b	b	b	b	b	b/d
B10 A (5R)	Donor	i5	b	b	b	k	k	d	d	d
B10. D2	Target	d	d	d	d	d	d	d	d	d

Boxed regions indicate the specificity of the antiserum against the target.

The procedures used for isolation and separation of the tryptic peptides of Ia polypeptides are described in Fig. 1. Table 1 gives the genetic constitutions of the mice used in the preparation of the alloantisera and the Ia antigens. The specificities of the antisera have been discussed elsewhere[10,11]. Reverse-phase HPLC has been used to separate peptides of biological significance[17] and tryptic peptides of globular proteins[18]. We now report its application to the separation of radiolabelled tryptic peptides of integral membrane proteins. We have found that the number of radiolabelled peptides which we detect by HPLC and conventional ion exchange, for both transplantation antigens (unpublished results) and Ia polypeptides, are comparable.

If the N-terminal homology observed between the E_α and E_β polypeptides and human Ia polypeptides continues throughout their entire structures, then from amino acid composition data for human Ia p29 (β) and p34 (α) polypeptides[15], we can expect 23–26 tryptic peptides per molecule. Freed has reported ~12 tritiated arginine-containing peptides for the E^k_β polypeptide using conventional ion-exchange chromatography[19]. We detected about seven tritiated tyrosine-containing peptides and about 15 leucine-containing peptides for the E^k_β polypeptide (Fig. 1). Accordingly, we are monitoring approximately 30–65% (7/23–15/23) of the tryptic peptides of the polypeptide.

Comparison of tryptic peptides of the E_β polypeptides shows that there are several common peptides and multiple peptide differences (Fig. 1). We conclude that multiple amino acid differences are present in several regions of the E_α polypeptides. In contrast, the E^k_α and E^d_α polypeptides do not show any definite peptide differences (Fig. 1). One major peptide of the leucine map of the E^d_α polypeptide seems to be broader than its E^k_α counterpart; we cannot explain this difference. As comparative peptide maps overemphasise amino acid differences and as we cannot detect any definitive peptide differences, we conclude that the E_β polypeptides must be extremely similar, if not identical.

These comparative peptide maps permit us to draw several interesting genetic and evolutionary conclusions about the Ia polypeptides.

(1) Homology relationships. Several Ia polypeptides of the I–A subregion have been analysed by HPLC of tryptic digests[12]. The E_α and A_α polypeptides share at most one tyrosine-containing peptide. The E_β and A_β polypeptides generally share only one or two peptides, although the A^k_β and E^k_β polypeptides show co-chromatography of four of seven tyrosine peptides. We do not know whether this apparent similarity is fortuitous or

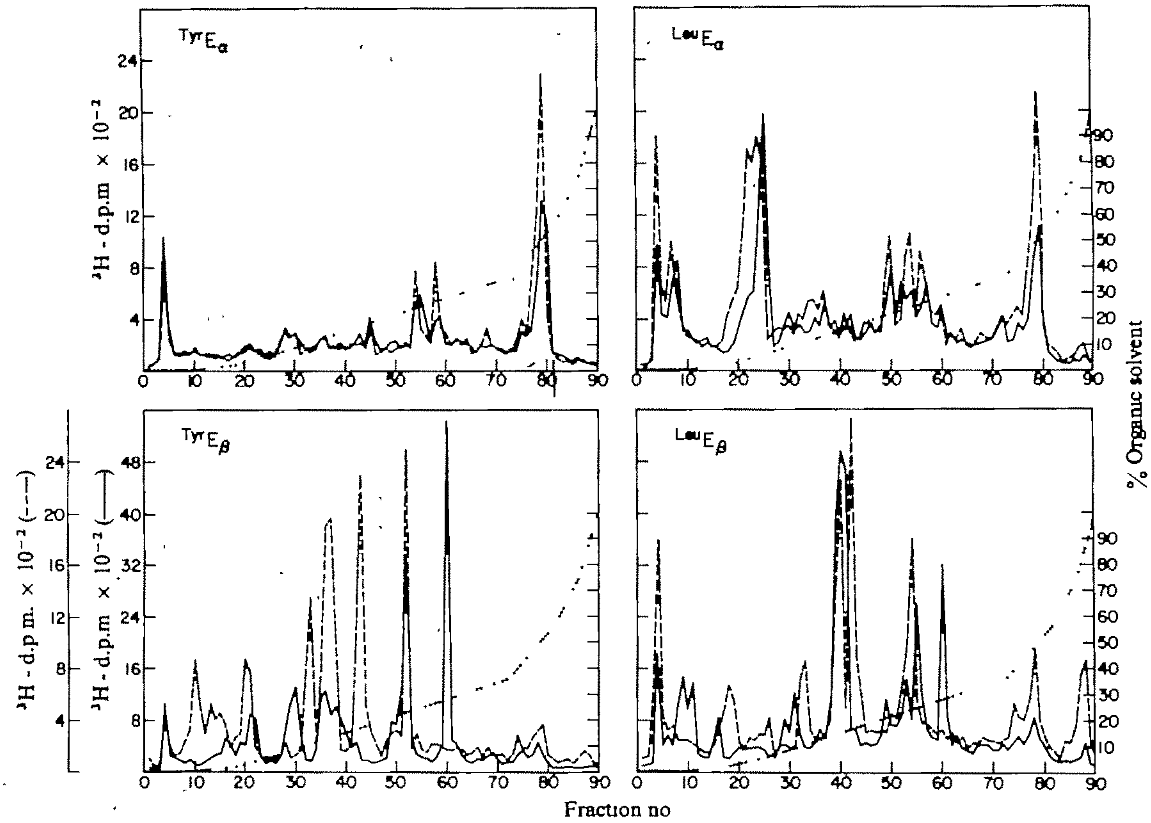

Fig. 1 HPLC tryptic peptide maps of α and β polypeptides of Ia molecules from the I–E subregion. ——, Peptides of the k haplotype, – – –, peptides of the d haplotype; · · ·, the concentration gradient of organic solvent used. Fraction number is plotted on the abscissa and the radioactivity of each fraction is plotted on the left ordinate. Ia antigens were biosynthetically radiolabelled and isolated by previously described procedures[10]. Splenic lymphocytes were cultured in the presence of either 1 mCi of tritiated tyrosine or 1 mCi of tritiated leucine. Radiolabelled Ia antigens were isolated by immunoprecipitation using specific alloantisera and *Staphylococcus aureus* Cowan I (ref. 23). The α and β polypeptides were separated by SDS–polyacrylamide electrophoresis[24] using 10% gels run in reducing conditions. The proteins were eluted from the gels in 0.01% SDS mixed with 0.5 mg porcine immunoglobulin and lyophilised. The polypeptides were reduced, alkylated and digested by the method of Brown[25] modified as follows. The polypeptides were boiled for 5 min in 0.5 ml of 0.6 M Tris, 0.02 M EDTA, 9% SDS, pH 8.3 buffer and reduced under argon for 3 h at 37 °C with dithiothreitol (0.025 M). The proteins were then alkylated in the dark for 1 h at room temperature using iodoacetamide (0.05 M) and reagents were then removed by centrifugation through a 2.5-ml column of Sephadex G-25 equilibrated with 0.05 M Tris, 2% 2-mercaptoethanol, 2% SDS, pH 7.5 (ref. 26). The proteins were then precipitated with 20% trichloroacetic acid, washed, dried and digested for 18 h at room temperature in 0.2 ml 0.05 M ammonium bicarbonate using 10 µl of trypsin–L(tosylamide-2-phenyl)-ethyl-chloromethyl-ketone (Worthington) (10 mg ml^{-1} in 0.001 M HCl). Another 10 µl of trypsin solution was added and after 4 h the resulting peptides were lyophilised. The peptides were analysed on a DuPont 830 HPL chromatograph using a 25-cm Zorbax-CN column at 49 °C. The column was initially equilibrated with 0.1 M sodium phosphate buffer, pH 2.1, and the peptides were eluted with a gradient of acetone (Burdick and Jackson). 1-ml fractions were collected every minute directly into scintillation vials and evaporated to dryness. 0.5 ml 0.01% SDS and 4 ml Aquasol-2 (NEN) were added to each vial and the radioactivity was then determined on a Beckman LS9000 scintillation counter

whether it signifies sequence homologies. In any case, it seems that the α and β polypeptides from the I–A and I–E subregions are not very closely related to one another.

(2) Genetic mapping. The mice from which the E^k and E^d molecules were isolated are congenic, presumably having distinct H-2 complexes superimposed on genetically identical B10 backgrounds. Haplotype-associated amino acid or peptide differences have been observed in the E_β polypeptides, which implies that the genes (structural or regulatory) controlling the synthesis of the E_β polypeptides are located within the H-2 complex. As the E_α gene product is apparently not polymorphic, no conclusions can be drawn about whether it lies in the H-2 complex. If the E^k_α and E^d_α polypeptides are indeed identical, the serological determinants on Ia molecules of the I-E subregion must reside on the corresponding E_β polypeptides.

(3) Complex allotypes. The E_β polypeptides exhibit multiple amino acid substitutions and can be defined as complex allotypes. The importance of distinguishing complex from simple allotypes, such as sickle-cell haemoglobin and its normal counterpart, is that a more complicated genetic organisation or evolutionary history is required to explain the generation of complex allotypes[26]. The α and β polypeptides of the I–A subregion and the K and D transplantation antigens, and the β polypeptide of the I–E subregion are all examples of complex allotypes. Thus, five distinct genes (or gene systems) encoded by the H-2 complex exhibit the phenotypic behaviour of complex allotypes.

Jones *et al.*[21,22] have reported that immunoprecipitates made using antisera having Ia specificities give a remarkably complex series of spots when analysed by two-dimensional gel electrophoresis and that these immunoprecipitates contain an invariant polypeptide of MW 31,000. We are now refining our peptide map procedures to identify which of these polypeptides have been analysed by amino acid sequence and peptide map techniques.

Promotion of microtubule assembly *in vitro* by taxol

TAXOL (Fig. 1) was isolated from the plant *Taxus brevifolia* (western yew) by Wani *et al.*, who reported that the molecule has antitumour activity in several experimental systems[1]. In our laboratory we have found that taxol, a low molecular weight neutral compound, completely inhibits division of exponentially growing HeLa cells at low concentrations of drug (0.25 μM) that have no significant effects on DNA, RNA or protein synthesis during a 4-h incubation with the cells. HeLa cells incubated with taxol for 20 h are blocked in late G_2 and/or M (ref. 2). We report here that taxol acts as a promoter of calf brain microtubule assembly *in vitro*, in contrast to plant products such as colchicine and podophyllotoxin, which inhibit assembly. Taxol decreases the lag time for microtubule assembly and shifts the equilibrium for assembly in favour of the microtubule, thereby decreasing the critical concentration of tubulin required for assembly. Microtubules polymerised in the presence of taxol are resistant to depolymerisation by cold (4 °C) and $CaCl_2$ (4 mM).

Many models have been proposed for the microtubule assembly system used in these experiments[3], but the exact mechanism for microtubule assembly *in vitro* is not known; the conditions required have been described elsewhere[4]. A dynamic equilibrium of microtubules with tubulin dimers has been demonstrated *in vitro*[5–7]. Our standard conditions for assembly in a final volume of 1.0 ml at 37 °C are: 1 mM EGTA, 0.5 mM $MgCl_2$, 1 mM GTP, 0.1 M 2-[*N*-morpholino]ethane sulphonic acid (MES) at *p*H 6.6 and 1 mg ml^{-1} tubulin.

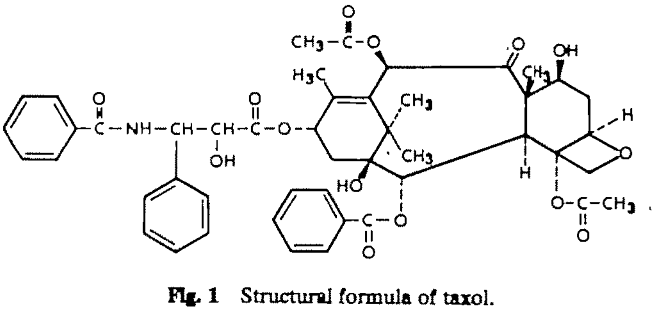

Fig. 1 Structural formula of taxol.

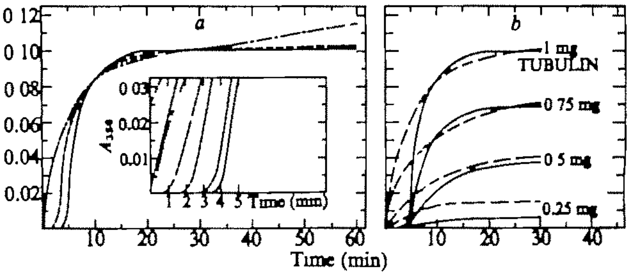

Fig. 2 Effect of taxol on microtubule assembly kinetics. Calf brain tubulin was prepared by two cycles of assembly–disassembly[19] and stored at −20 °C in MES buffer (0.1 M MES, 1 mM EGTA, 0.5 mM $MgCl_2$, adjusted to *p*H 6.6 with NaOH) containing 1 mM GTP and 4 M glycerol. Before each experiment the tubulin was dialysed for 3 h at 4 °C against 100 vols of MES buffer, and centrifuged at 120,000*g* for 20 min at 4 °C. Tubulin present in the supernatant was maintained in an ice bath. Tubulin purified by this method is 85% pure as determined on 3–27% SDS-polyacrylamide gradient reducing slab gels[20]. Assembly was monitored by the method of Gaskin *et al.*[5]. The cuvettes (1 cm path) containing MES buffer, drug and 1 mM GTP were kept at room temperature before addition of tubulin and shifting to 37 °C. Turbidity measurements were made at 350 nm every 20 s on a Gilford spectrophotometer equipped with an automatic recorder and a thermostatically regulated sample chamber. Taxol was dissolved in dimethyl sulphoxide at 10 mM and stored at −20 °C. The final concentration of dimethyl sulphoxide (0.5%) had no detectable effect on the assembly of tubulin. *a*, Standard assembly conditions: no additions (——); 0.05 (–· · ·–); 0.1 (–––); 0.5 (–– ·); 1 (· · ·); 5 (–·–); and 10 (–· · · ·–) μM taxol. *b*, Standard assembly conditions: 0.25, 0.5, 0.75 or 1 mg ml^{-1} tubulin, 37 °C. No additions (——); 5 μM taxol (–·–).

Microtubule assembly was monitored by the increase in turbidity[5] and by electron microscopy. In our conditions, taxol causes a dose-dependent decrease in the lag time for assembly (Fig. 2*a*); whereas the control has a 3.5 min lag time, 5 μM taxol essentially eliminates the lag time. The control assembly progress curve is sigmoid, but addition of 5 μM taxol gives hyperbolic kinetics. Ribbon structures and dimers are seen with the electron microscope at 30 s with 1 mg ml^{-1} tubulin and 5 μM taxol; in the control there are only rings and dimers (data not shown). The ribbon structures observed at 30 s with taxol are probably intermediates in assembly, as only microtubules are seen at 30 min. Figure 2*b* demonstrates that taxol decreases the lag time independently of tubulin concentration.

Microtubules polymerised in the presence of 10 μM taxol are shorter than in the control. Average microtubule lengths were determined by electron microscopy[7] at 30 min, a time at which equilibrium was apparently reached. The average length of the control microtubules is 4.12 ± 2.12 μm, whereas the microtubules polymerised in the presence of 10 μm taxol have an average length of 1.49 ± 0.65 μm.

Microtubules were polymerised in the absence and presence of 5 μM taxol for 30 min at 37 °C, and then chilled in an ice bath for 30 min. By electron microscopy, microtubules were seen only in the drug-treated sample. Ribbon structures, but no microtubules, were observed when polymerisation was carried out at 4 °C for 30 min in the presence of 50 μM taxol. Microtubules assembled at 37 °C in the presence of 10 μM taxol were completely resistant and those assembled in the presence of 5 μM taxol were partially resistant to depolymerisation by 4 mM $CaCl_2$ (Fig. 3*a*). Dimers, rings and microtubules were present 30 min after the addition of $CaCl_2$ to microtubules assembled in the presence of 5 μM taxol. Figure 3*b* demonstrates that microtubule assembly will take place in the presence of 4 mM $CaCl_2$ and 5 μM taxol.

Microtubules were centrifuged at 120,000*g* for 30 min and resuspended in 1 ml of MES buffer with or without 10 μM taxol. After 4 min, 4 mM $CaCl_2$ was added to the resuspended samples. Continuous turbidity measurements and electron microscopy indicated that no microtubules were present in the non drug-treated sample after the addition of $CaCl_2$, whereas

0028-0836/79/0277—0665$01 00

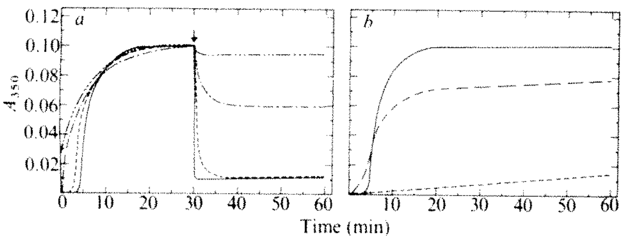

Fig. 3 Effect of $CaCl_2$ on microtubules assembled *in vitro* in the presence of taxol. *a*, Standard assembly conditions. No additions (——); 0.1 (– – –); 5 (– · –); and 10 (– · · · –) μM taxol. $CaCl_2$ is added at a final concentration of 4 mM at 30 min (↓). *b*, Assembly conditions as in (*a*). No additions (——); 4 mM $CaCl_2$ plus 5 μM taxol (– · –); 4 mM $CaCl_2$ (– – –).

the taxol-treated microtubules were resistant to depolymerisation by $CaCl_2$. Such experiments suggest that a taxol binding site is available on the intact microtubule.

Tubulin (7.7 μM; 1 mg ml^{-1} total protein) was assembled in standard conditions in the absence and presence of 10 μM taxol for 20 min. After centrifugation at 120,000*g* for 30 min, the amount of protein in the pellets and supernatants was determined[8]. In the absence of taxol, 0.57 mg of protein was pelleted by centrifugation. When tubulin was assembled in the presence of 10 μM taxol, 0.78 mg of protein was pelleted. A maximum amount of protein was pelleted at a taxol concentration approximately stoichiometric with the dimer concentration.

There is evidence that microtubule assembly *in vitro* takes place by the nucleated condensation mechanism of Oosawa and Kasai[9]. This model is supported by a requirement for a critical concentration (C_c) of protein to achieve assembly, and by tubulin–microtubule equilibrium data[5,6,10]. The critical concentration is approximately the inverse of the apparent microtubule propagation equilibrium constant (K_p^{app}) for the addition of a single tubulin dimer to a pre-existing microtubule[5].

$$\text{tubulin dimer} + \text{microtubule (length } n) \overset{K_p^{app}}{\rightleftharpoons}$$

$$\text{microtubule (length } n+1) \qquad \text{let } K_p^{app} = C_c^{-1}$$

Below the critical concentration, no microtubules are found by light scattering, electron microscopy or sedimentation velocity[5,10,11].

Taxol causes a decrease in the critical concentration of protein required for microtubule assembly *in vitro* (Fig. 4). Protein concentration was determined in both the supernatants and pellets. In the absence of drug (Fig. 4*a*), the critical concentration observed is 0.2 mg ml^{-1}(1.8 μM), a value which corresponds well with that previously reported[5]. In the presence of 5 μM taxol (Fig. 4*b*) the critical concentration decreased to ≤0.01 mg ml^{-1}(0.08 μM). The values for the apparent standard free energy (ΔG°_{app}) of addition of a tubulin dimer to a growing microtubule have been calculated using the formula $\Delta G^\circ_{app} = -RT \ln K_p^{app}$. For control and taxol-treated (5 μM) preparations, respectively, values for K_p^{app} were 5.7×10^5 and $\geq 1.1 \times 10^7$ l mol^{-1}, and for ΔG°_{app}, −8.0 and ≤ −10.0 kcal mol^{-1}. As taxol renders microtubules resistant to depolymerisation, the change in the apparent equilibrium constant could be the result of a reduced dissociation rate constant.

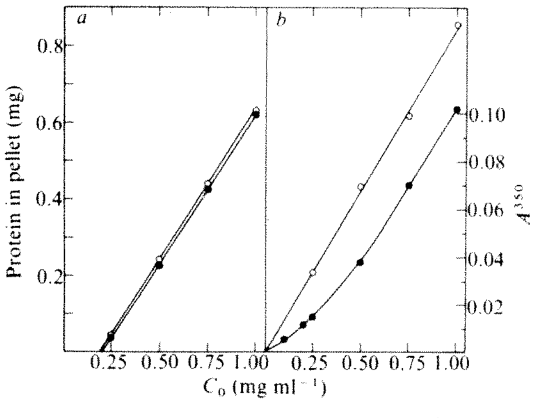

Fig. 4 Comparison of critical concentrations determined by centrifugation (120,000*g* at 25 °C for 30 min) of microtubules (○) and turbidity measurements (●) in the absence (*a*) and presence (*b*) of 5 μM taxol. C_0 is the total protein concentration. Determinations are made after a 30 min incubation in standard assembly conditions.

Turbidity at 30 min did not change appreciably compared with that of the control until the protein concentration was less than 0.25 mg ml^{-1} (Figs 2*b*, 4). Microtubules, tubulin hoops[12] with less than 13 protofilaments, and ribbons were observed at 0.1 mg ml^{-1} tubulin in the presence of 5 μM taxol at 30 min, whereas the control contained no structures (Fig. 5). At 1 mg ml^{-1} tubulin and 5 μM taxol, essentially no hoop structures or ribbons, only short microtubules, were found at 30 min.

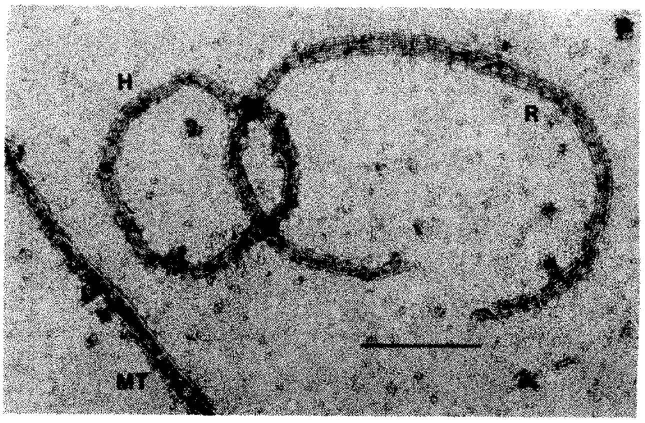

Fig. 5 Electronmicrograph of the structures assembled in the presence of 0.1 mg ml^{-1} tubulin and 5 μM taxol at 30 min in standard conditions. Structures were negatively stained with uranyl acetate[21]. MT, Microtubule; H, hoop; R, ribbon. Scale bar, 0.2 μm.

More and shorter microtubules are polymerised when assembly takes place in the presence of taxol. These shorter microtubules do not scatter light to the same degree as the control microtubules at the identical protein concentration[5]. However, as there are more of the short microtubules than there are of the control microtubules, there is very little difference in the amount of turbidity that develops at concentrations of protein above 0.25 mg ml^{-1} at 30 min. If the average length of the microtubules and the mass of protein pelleted after polymerisation in the presence of 10 μM taxol are taken into account, there is an approximate 3.8-fold increase in the number of microtubules (nucleations) in the drug-treated sample.

Phosphocellulose-purified tubulin, which is free of microtubule-associated proteins[13], will assemble in the presence of stoichiometric concentrations of taxol. Taxol also promotes assembly of charcoal-treated tubulin (1 mg ml^{-1}), which contains substoichiometric concentrations of GDP at the exchangeable site[14]. The drug has no effect on GTP or GDP hydrolysis in our microtubule preparations (data not shown).

There are similarities between microtubule and F-actin polymerisation. A nucleated condensation mechanism for the polymerisation of F-actin has previously been described[15]. Opposite-end assembly and disassembly have been shown for both F-actin polymerisation[16] and microtubule polymerisation at steady state *in vitro*[17]. Bound nucleoside triphosphate is hydrolysed during polymerisation in both systems. Phalloidin, a bicyclic peptide from the toxic mushroom *Amanita phalloides*, has been reported to accelerate the polymerisation of F-actin and confer resistance to depolymerisation[18]. Phalloidin and taxol represent natural products that enhance self-assembly systems. From our results, we consider that there may be low molecular weight cell constituents with activity similar to that of taxol which may be involved in the regulation of microtubule assembly in the cell.

We thank Dr Felicia Gaskin for advice and assistance, and Dr Richard Burger for his criticism of the manuscript. Molecular basis of thermostability in the lysozyme from bacteriophage T4

MOST proteins are denatured at temperatures above 50–60 °C, although some enzymes, especially those from thermophilic organisms, remain active at temperatures up to 80–90 °C. The determination of the three-dimensional structure of the thermostable protease thermolysin showed that heat-stable proteins do not contain unusual structural features absent from less stable proteins[1,2]. Furthermore, the amino acid sequences of similar proteins from both mesophilic and thermophilic sources have been shown to be homologous, suggesting that the respective structures are similar[3,4]. Nevertheless, such homologous amino acid sequences also include many differences which obscure those amino acid changes actually responsible for differences in thermostability. We report here the structure of a temperature sensitive (ts) mutant of T4 phage lysozyme. This permits the first direct comparison of two protein structures in which all differences are directly related to a change in thermal stability. It is shown that, except for the replacement of a partially exposed arginine by a histidine, the three-dimensional structure of the ts lysozyme is virtually identical with that of native lysozyme.

Bacteriophage T4 lysozyme, an endoacetylmuramidase, is produced late in the infection of *Escherichia coli* by T4 bacteriophage. It cleaves the bacterial cell wall, allowing the release of the progeny phage particles[5]. The amino acid sequence of the lysozyme has been determined[6], crystals suitable for detailed X-ray study have been obtained, the three-dimensional structure determined[7,8] to a resolution of 2.4 Å, and a thermodynamic analysis of the folding of the enzyme is underway (ref. 9 and unpublished results).

Since Streisinger developed a technique for identifying and isolating phage particles with mutations in the lysozyme gene[10], many different mutations in the lysozyme gene have been identified, the resultant changes in the amino acid sequence of the protein determined, and the properties of these mutant lysozymes discussed in the light of the three-dimensional structure of the wild-type enzyme[8,11].

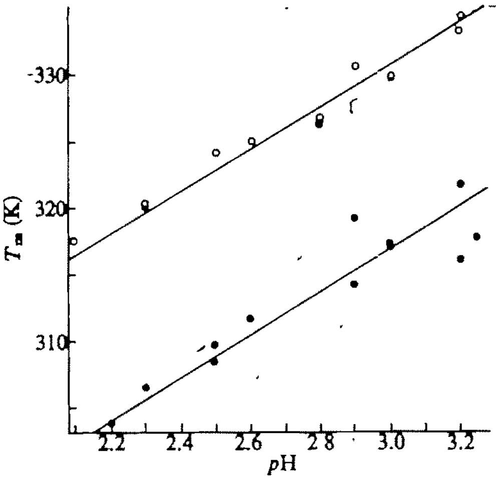

Fig. 1 The melting temperature (T_m) of wild-type (○) and temperature-sensitive (●) lysozymes as a function of *p*H. Denaturation was monitored by following changes in peptide circular dichroism at 223 nm. Details of the experimental method and of the analysis used to calculate T_m are given elsewhere[9]. Solvent conditions were as follows: 0.2 M NaCl, 10^{-4} M dithiothreitol, 10^{-6}–10^{-5} M lysozyme.

Lysozyme mutant strains were generated by use of 2-aminopurine, which induces single base pair substitutions. Temperature-sensitive mutants were selected applying the recognition method for lysozyme gene mutations[10]. Plaques of wild-type phage on plates incubated at 37 °C become surrounded by large haloes after exposing the plate to chloroform vapour. The haloes result from phage lysozyme diffusing from the plaque into the surrounding area and lysing the chloroform-treated bacteria. Halo size is a direct measure of the stability of the lysozyme. For ts mutants, the halo size decreases with increasing temperature on plates incubated at 30, 37 and 41 °C whereas wild-type plaque haloes stay large. By testing the ability of the mutant phage to recombine with a number of precisely mapped deletion mutants in the lysozyme gene, the locus of the amino acid change was determined to lie between residues 65 and 105.

The ts mutant lysozyme was purified according to the standard procedure for wild-type lysozyme[12], and was found to have a melting temperature about 14° lower than that of the native enzyme (Fig. 1). Crystals isomorphous with the native enzyme were obtained by the standard procedure[8]. The largest cell dimension change, in *c*, was 0.4 Å. We therefore were able to analyse the mutant by the standard difference Fourier technique (for example see ref. 13). A data set to 2.4 Å resolution was collected and a difference electron density map calculated between the native and the mutant lysozyme. Full details of the structure determination will be published elsewhere.

The difference density map is essentially featureless except at the location of the side chan of Arg 96, where a strong negative feature is seen at the site of the guanidinium group, and a positive peak overlaps the positions of C^{γ} and C^{δ} (Fig. 2). Clearly, Arg 96 in wild-type lysozyme has been replaced in the ts

0028-0836/79/0277—0667$01 00

mutant by an amino acid with a medium-size side chain. The location of the substitution is consistent with that determined genetically. Determination of the amino acid composition of the mutant lysozyme revealed that there were two histidines, compared with one in the wild-type enzyme, indicating that Arg 96 has been replaced by a histidine. Furthermore, the electron density map (Fig. 2) also strongly suggests that the ts lysozyme has a histidine at position 96.

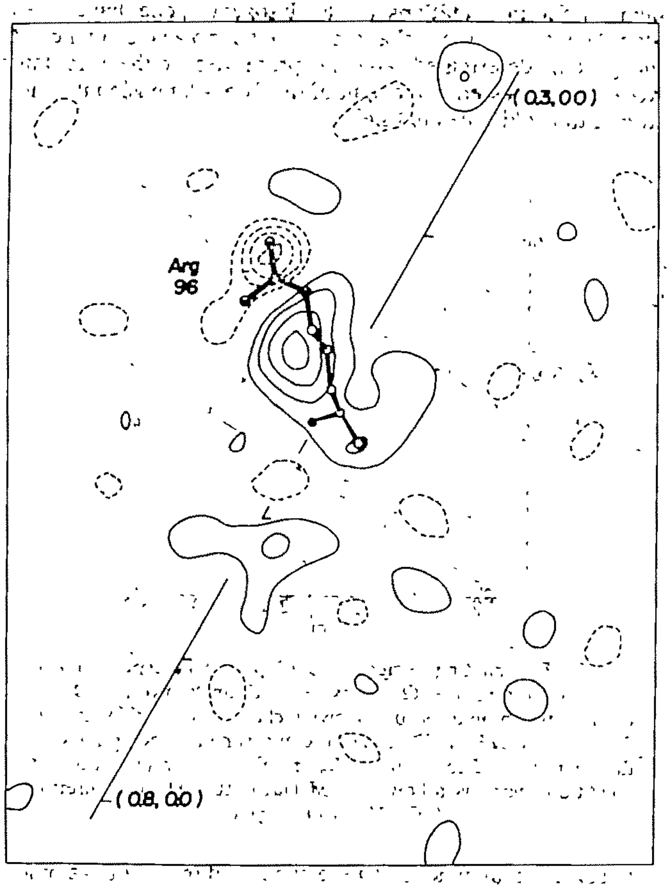

Fig. 2 Portion of the map showing the difference in electron density between native phage lysozyme and the temperature-sensitive mutant lysozyme with Arg 96 replaced by a histidine. The section shown, $z = 11/132$, approximately intersects the side chain of Arg 96. Contours are drawn at arbitrary equal intervals, with positive contours solid and negative broken. In the superimposed side chain of Arg 96, carbon atoms are represented by open circles and nitrogen by half solid circles.

In the native enzyme, the side chain of Arg 96 is well-ordered, and lies on the protein surface between the ring of Tyr 88 and the main chain and C^{β} of Leu 91 (Fig. 3). The hydrocarbon portion of the arginine side chain contributes to the major hydrophobic core of the C-terminal lobe of the molecule[7,8]. Substitution of an imidazole at this position presumably destabilises the hydrophobic core somewhat, providing at least part of the molecular basis for the observed temperature sensitivity. The imidazole ring of His 96 lies parallel to the ring of Tyr 88, and appears to donate a hydrogen bond to the carbonyl oxygen of the same residue (Fig. 3), possibly destabilising the α-helix 82–90. Detailed analysis of these interactions will take some time.

The main finding, however, which appears clearcut, is that the three-dimensional structure of the ts lysozyme is virtually identical with that of native lysozyme, except for the replacement of a partially exposed arginine by a histidine. Excluding residue 96, there is no evidence for structural changes larger than a few tenths of an angstrom. This finding is consistent with our earlier suggestion[2,14], based on the structure of the thermostable protease thermolysin, that differences in the thermostability of proteins are, in general, due to subtle changes in hydrophobic interactions, hydrogen bonds, and so on, and not to a single determinant such as metal binding or changes in secondary structure. In agreement with Perutz[15], our study shows that extra energy of thermal stabilisation can be provided without disturbance of the tertiary structure of the protein, although we do not see any change in the number of salt bridges in the mutant lysozyme. Also, our results confirm general thermodynamic arguments which suggest that the net free energy of stabilisation of proteins is small, and derives from a delicate balance between large stabilising forces, principally due to hydrophobic interactions, and large destabilising ones, principally due to chain entropy[16–18].

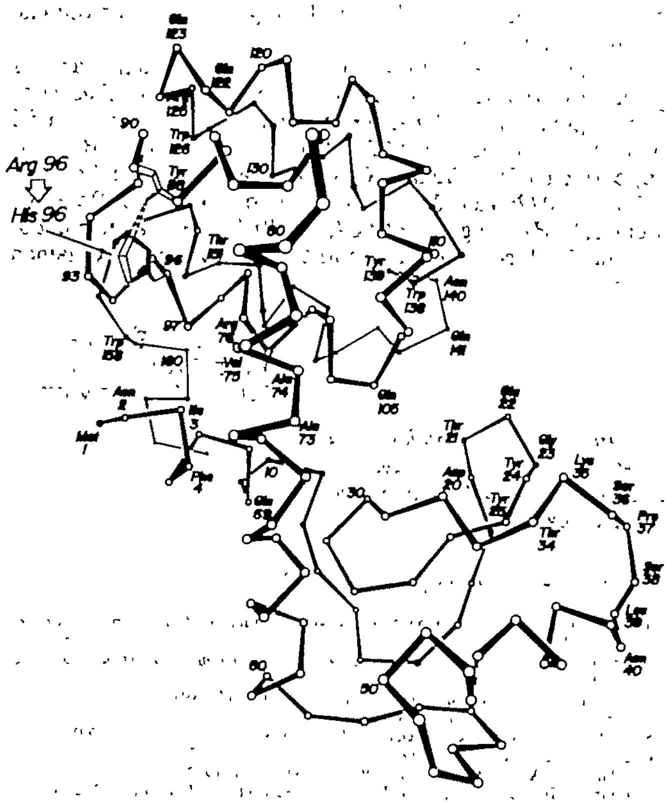

Fig. 3 Schematic drawing of the backbone of bacteriophage T4 lysozyme showing the location of His 96 in the temperature-sensitive mutant. (Adapted from ref. 8).

In addition to the mutant described here, three other temperature sensitive mutant lysozymes, with amino acid substitutions in other parts of the molecule, have been crystallised isomorphously with the wild-type enzyme. Clearly, these mutant lysozymes also have structures similar to that of the native enzyme. We hope that structural comparisons of these and other modified lysozymes will eventually provide a detailed accounting of the contributions of individual amino acid residues to the stability of a protein. Related studies of mutant lysozymes with modified activity should help clarify the mechanism of action of the enzyme.

We thank Kerrie Rine for technical assistance; Drs G. Streisinger and J. Owen for advice on lysozyme genetics, and Dr J. Schellman for discussions on lysozyme stability. M.G.G. was supported by the Swiss NSF. This work was supported in part by NIH grants GM 21967, GM 20066 and GM 20195.

Effect of a local anaesthetic on hydrocarbon chain order in membranes

THE mode of action of anaesthetics has provoked considerable interest and speculation[1,2]. For tetrodotoxin[3], it is clear that direct interaction of the anaesthetic with the sodium channel blocks nerve conduction; in other cases changes in lipid bilayer structure, such as membrane expansion[2], fluidus expansion[1] or surface-charge modulation[4], have been invoked. Recently, a mechanism involving an increase in lipid bilayer thickness has been suggested from results obtained using black film techniques[5–7]. We have investigated the hydrocarbon chain length of a lecithin bilayer in the presence and absence of the anaesthetic benzyl alcohol[8,9] using high-field deuterium nuclear magnetic resonance (NMR) spectroscopy of specifically deuterated lipids[10–16], to determine the changes in bilayer structure that occur on addition of the anaesthetic alcohol. We report here that at concentrations used for local anaesthesia there is no change in membrane thickness. By comparison, cholesterol (at 0.3 mol fraction) causes an ~0.46 nm increase in membrane thickness. We therefore suggest that the amount of solvent (tetradecane) in black lipid membranes, and hence their thickness, may be influenced by the presence of benzyl alcohol and cholesterol[5].

Figure 1*a* shows the effect of benzyl alcohol on the deuterium quadrupole splitting of a dimyristoyl lecithin labelled as $^2H_2$ in the sixth position of the 2-chain. As the concentration of benzyl alcohol increases, the quadrupole splitting and therefore the order parameter of the labelled methylene segment[13] decreases. This suggests a decrease in order of the 2-chain; cholesterol causes an increase[10,11,15,16]. Determination of the change in order parameter at each segment in the hydrocarbon chain permits evaluation of the total change in hydrocarbon chain length[10,13,17]. We determined the quadrupole splittings, and the order parameters, for a range of dimyristoylphosphatidylcholines labelled (as C^2H_2 or C^2H_3) at one of positions C-2, C-3, C-4, C-6, C-8, C-10, C-12, or C-14, in the 2-chain, at a total lipid–anaesthetic mol ratio of 1:3. In Fig. 1*b* representative spectra illustrate the effect of benzyl alcohol on the deuterium quadrupole splittings of a series of ^2H-labelled phosphatidylcholines, and Fig. 1*c* shows the effects produced by benzyl alcohol and cholesterol on these splittings. Benzyl alcohol and cholesterol have opposite effects on the order of the phosphatidylcholine acyl chains. Benzyl alcohol (above the gel–liquid crystal phase transition temperature of the phospholipid) causes a decrease in hydrocarbon chain quadrupole splitting or order parameter; cholesterol (above the gel–liquid crystal phase transition temperature of the phospholipid) causes an increase in hydrocarbon chain quadrupole splitting, or order parameters. Qualitatively, therefore, benzyl alcohol decreases and cholesterol increases hydrocarbon chain order.

At anaesthetic concentration, however, there is no effect of benzyl alcohol on membrane thickness. Local anaesthetic concentrations of benzyl alcohol are 4 mM for rat phrenic nerve and 12 mM for frog sciatic nerve[9]. At 40 °C the partition coefficient of benzyl alcohol between multi-bilayers of dimyristoyl

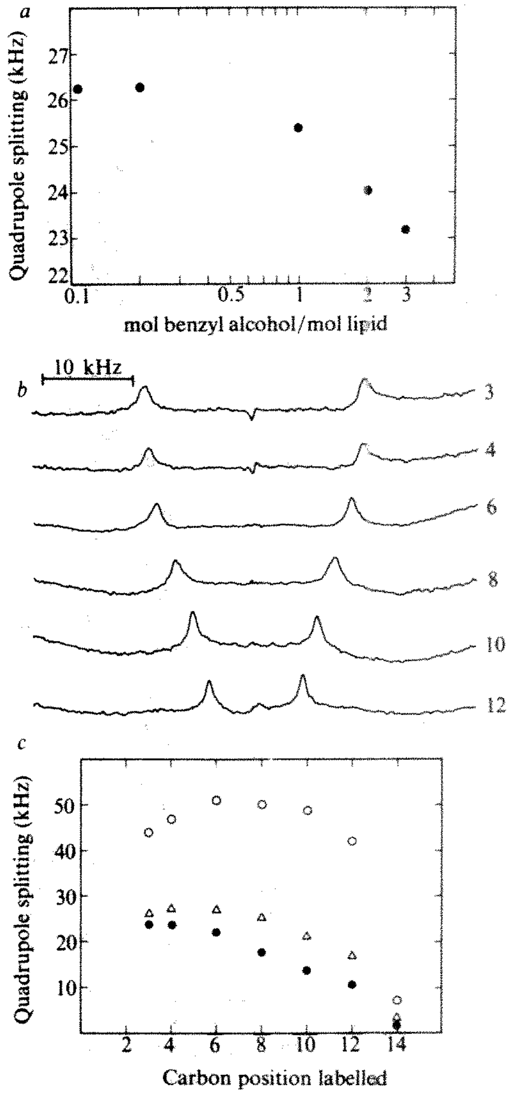

Fig. 1 Effects of benzyl alcohol, and of cholesterol, on deuterium NMR quadrupole splittings of specifically ^2H-labelled dimyristoylphosphatidylcholines. *a*, Graph of the quadrupole splitting of 2-(6′, 6′-d_2)dimyristoylphosphatidylcholine (10 mg) dispersed in excess deuterium-depleted water (250 μl) containing benzyl alcohol at 38° C, as a function of the benzyl alcohol–lipid mol ratio. The pure lipid quadrupole splitting value is 26.2±0.5 kHz. *b*, Representative deuterium Fourier transform NMR spectra of dimyristoylphosphatidylcholines, labelled in the 2-chain as C^2H_2 at the positions indicated. The samples contained a benzyl alcohol–lipid mol ratio of 3:1; spectra were recorded at 38 °C. *c*, Graph of quadrupole splittings of specifically deuterated dimyristoylphosphatidylcholines as a function of position labelled in the hydrocarbon chain, in the presence and absence of benzyl alcohol (3:1 benzyl alcohol–lipid mol ratio) or cholesterol (30 mol % cholesterol). Pure lipid and lipid–benzyl alcohol data obtained at 38 °C, lipid–cholesterol data obtained at 30 °C. Deuterium NMR spectra were obtained using the Fourier transform method at 5.2T (corresponding to a deuterium resonance frequency of 34 MHz) on a homebuilt instrument[10]. The synthesis of dimyristoylphosphatidylcholines specifically deuterated in the 2-chain are described elsewhere[10]. Benzyl alcohol was added as an aqueous solution to dry phospholipid and the mixtures homogenised at about 40 °C. △, Dimyristoylphosphatidylcholine alone; ○, in the presence of cholesterol; ●, in the presence of benzyl alcohol.

lecithin and water is 13.9 according to Katz and Diamond[18]. At local anaesthetic levels, the benzyl alcohol–dimyristoyl lecithin mol ratio is 0.04–0.11. As may be seen from Fig. 1*a* there is no decrease in the electric quadrupole splitting from the pure lipid value of 26.2±0.5 kHz in this range of benzyl alcohol concentration, a result consistent with spin-label studies[9], although on a different timescale and without the possible complications of a perturbing probe effect.

At higher benzyl alcohol–dimyristoyl lecithin mol ratios there is a decrease in quadrupole splitting (or order parameter) with increasing concentration of benzyl alcohol, which agrees with spin-label studies[9] (Fig. 1). From these results it is relatively straightforward to determine quantitatively the projections of each C–C segment onto the bilayer normal[10,13,17], and so determine the effective length of the hydrocarbon chain, or the total membrane thickness[10,13,17,19]. Calculated chain lengths are rather insensitive to chain tilt. For example, for pure dimyristoylphosphatidylcholine at 60 °C, the distance from C-2 to C-14 is 10.2(6) Å assuming no chain tilt, or 10.5(2) Å assuming a gaussian distribution of chain orientations with a probable tilt angle of 25° (refs 10, 17). Similar average chain lengths are obtained using flat or lorentzian distribution functions (E.O. and R. Jacobs, unpublished). Consequently, we obtain from the NMR data a model-insensitive value for the average chain length, or membrane thickness. These lengths are in excellent agreement with those determined using high-resolution neutron diffraction (D. Worcester, M. Meadows, D. Rice and E.O., unpublished). For example, 23 °C lecithin–cholesterol data give a total hydrocarbon region thickness of about 30–31 Å, and neutron diffraction measurements[10] indicate a thickness of about 33 Å (Table III of ref. 10). From the data in Fig. 1*b* and *c* we can calculate the thickness of the dimyristoylphosphatidylcholine membrane at 38° C and obtain values of about 2.5(0) nm for the hydrocarbon region thickness in the absence of benzyl alcohol and about 2.3(6) nm in the presence of benzyl alcohol. The fluidisation of the bilayer caused by benzyl alcohol[8,9] decreases the membrane thickness. Cholesterol (30 mol%) causes an increase in hydrocarbon chain order, corresponding to about a 0.46-nm increase in membrane thickness at 23 °C (ref. 10).

Previous workers[5,6] have found, using black lipid membrane capacitance and conductance measurements, a 1.2-nm increase in membrane thickness in the presence of benzyl alcohol, and a decrease in hydrocarbon region thickness in the presence of cholesterol. Although the fatty acid composition of the lecithin used in the black lipid membrane studies differed slightly from ours, neutron beam and X-ray diffraction measurements on the egg-lecithin–cholesterol system indicate no significant decrease in membrane thickness on addition of cholesterol[21–23]. Similarly, other ^{2}H NMR and electron spin resonance spin-label studies of egg lecithin and egg-lecithin–cholesterol systems indicate an ordering of the hydrocarbon chains by cholesterol[15,24,25], which must correspond to an increase in projected chain length. In the absence of hydrocarbon solvents, such as tetradecane, an increase in projected chain length must correspond to an increase in membrane thickness, as neutron and X-ray data rule out $\geqslant$0.2 nm-chain interdigitation.

We therefore suggest that the previous black lipid film results[5,6] may be attributable to the inclusion of variable concentrations of solvent tetradecane in the lipid membrane, the exact amount being a function of the amount of cholesterol or benzyl alcohol present.

Deuterium nuclear magnetic resonance results suggest that the direct effect of benzyl alcohol on membrane bilayer thickness is negligible at the anaesthetic levels commonly used in clinical studies. At much higher levels (corresponding to an ~30–80-fold overload) there are small (≈0.1 nm) decreases in membrane thickness which are consistent with recent X-ray and neutron-beam studies of the effects of gaseous general anaesthetics on lipid bilayer thickness[26]. Taken together, our results cast considerable doubt on the importance of membrane thickness changes as a factor in the mechanism of action of many anaesthetics.

We thank Mr Michael Meadows for carrying out preliminary experiments, and an anonymous referee for valuable comments. This work was supported by the USNSF, the USNIH, the American Heart Association, the Illinois Heart Association and the Alfred P. Sloan Foundation. E.O. is an Alfred P. Sloan Research Fellow.

X-ray diffraction patterns from molecular arrangements with 38-nm periodicities around muscle thin filaments

A SERIES of meridional and near-meridional reflections have been observed in X-ray diffraction patterns (ref. 1 and Fig. 1*a*) from the crab *Plagusia* leg muscle in the living, resting state, and have been attributed to troponin molecules which lie in pairs on thin filaments at 38-nm intervals. In the pattern (ref. 1 and Fig. 1*b*) obtained from the same muscle in rigor, the corresponding series of reflections was observed to have stronger intensities and higher order reflections. The reflections were interpreted as arising from both troponin and the cross-bridges. Electron micrograph[2] showed that cross-bridges occurred in symmetrical pairs around the thin filaments with a repeating distance of 38 nm in which one or a few closely spaced pairs may be included. Recently, reflections indexed as orders of 76 nm in X-ray diffraction patterns from insect flight muscle in rigor[3] and those from scallop striated muscle in rigor[4] have also been interpreted in terms of the cross-bridges attached in pairs to thin filaments with a repeating distance of 38 nm. We report here a method that enables us to analyse diffractions generated by molecular arrangements of this type. These arrangements are described by a set of identical helices, and the systematic modulation of intensities, indexed as orders of 76 nm, is interpreted in terms of displacement between these helices.

ENERGY AND THE ENVIRONMENT

Democratic Decision Making

Edited by J. Surrey, Christian Lenzer, C. Phipps and J. Valleix

The outcome of a lively conference at the Council for Europe in Strasbourg, this book examines the challenges facing Europe over the next quarter-century arising from the complex and interrelated problems of energy and environment policy

The stark choice confronting politicians the report says, is between on the one hand, allowing societies to maintain present life-styles and trends and neglecting the risk of future resource scarcity, and on the other hand of preparing public opinion for unpopular decisions needed to avert future crisis.

Contents

THE WELLCOME TRUST

Competitive Awards for 1979

· Mental Disorders · Neurology · Veterinary Medicine · Toxicology

The Wellcome Trustees seek to encourage research in areas which they have identified as requiring special attention, by considering applications, on a competitive basis, for substantial research programmes over a period of up to five years. These awards are only available for research in the United Kingdom.

Research into Mental Subnormality

Award totalling £150,000 over 5 years

The scientific basis of the proposal may be in any of the basic sciences relevant to the field, but preference will be given to work with clinical applications or implications. (Ref: CA/MS/N).

Research into Pain

Award totalling £150,000 over 5 years

Research concentrating on peripheral aspects of pain, such as pain signals and their origin, the conditions giving rise to them, and the mechanisms involved, will be given priority, as will proposals linking research in basic science and clinical departments. (Ref: CA/P/N).

Veterinary Medicine

Award totalling £150,000 over 5 years

The Trustees are seeking research proposals for work in any field linking animal and human medicine. (Ref: CA/VET/N).

Research into Toxicological Mechanisms

Awards totalling £500,000

The Trustees are seeking substantial proposals of widely varying kinds for research into the basic mechanisms of toxicity They consider that this is not a subject that can develop in isolation and therefore expect that proposals will contain a strong collaborative element It is their hope that their support will lead to the establishment of a continuing nucleus of toxicological study For example, this support might make possible the appointment of a lecturer in toxicology who would act as the centre of a group including, perhaps, a pharmacologist, a biochemist, a chemist, a clinician and an epidemiologist

It is not the intention that these awards should be used to support toxicological work as an appendage to other studies or to aid the development of an industrial or epidemiological monitoring system Nor is it the immediate aim to foster teaching programmes, although it is hoped that these may develop later (Ref. CA/TOX/N).

Applicants should send a two-page summary of their research proposals, quoting the appropriate reference, and should also indicate how they would allocate the funds requested Following consideration of these summaries selected applicants will be invited to submit detailed proposals

The closing date for summary proposals is 16th March 1979 and they should be sent to The Wellcome Trust, 1 Park Square West, London NW1 4LJ. Tel: 01-486 4902.

Circle No. 16 on Reader Enquiry Card.

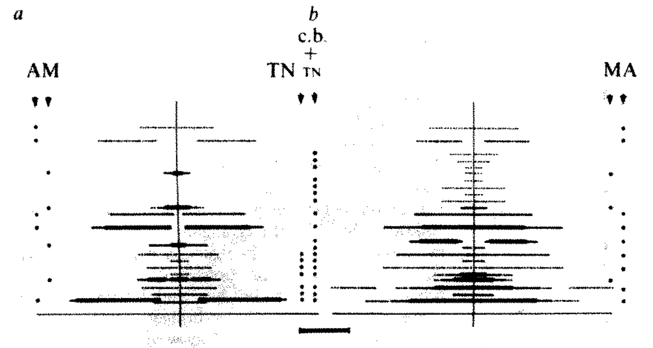

Fig. 1 Schematic representation of X-ray diffraction patterns[1] from crab *Plagusia* leg muscle in the living resting muscle (*a*), and in rigor (*b*). In addition to actin layer lines (marked by A) and meridional reflections (marked by M) attributed to myosin projections on the surface of the thick filaments, there is a series of meridional and near-meridional reflections (including intensities observed at $<0.07\ \text{nm}^{-1}$ on some of the actin layer lines) which were indexed as orders of 2×38 nm. In *a*, the reflections (marked by TN) were seen up to the 9th order, whereas in *b* those (marked by c.b. + TN) were observed up to the 24th. Thick solid lines, solid lines and dotted lines represent intensities observed even on the third film, up to the second one and on only the first film of each set, respectively. Bar, $0.1\ \text{nm}^{-1}$.

The thin filaments consist of actin, tropomyosin and troponin in a molar ratio of 7:1:1. The actin helix has a symmetry of 28/13 (28 molecules are included in 13 turns of the short-pitch helix) in the crab leg muscle in rigor. If we assume that these protein molecules interact with each other at specific sites, then the arrangement of troponin can be described by two identical 2/1 helices as shown in Fig. 2*a*. Axial displacement (Δz) and azimuthal rotation ($\Delta\phi$) between two molecules in pairs are specified by *k* multiple of those values between adjacent two-actin subunits along the 28/13 actin helix, where *k* is an odd integer. Ohtsuki[5,6] proposed a plausible model with $k = 1$, which remains to be proved.

Uniformly spaced layer lines, indexed as orders of 76 nm, are predicted from the single 2/1 helix as shown in Fig. 3*a*. Every even (odd) order Bessel function contributes to every even (odd) order layer line. The addition of another 2/1 helix results in a systematic intensity modulation which depends on *k*. As there is no trace of lattice sampling on the layer lines in the actual resting and rigor patterns from the crab leg muscle, we propose that the cylindrically averaged intensity[7] on each layer line can be written as

$$\langle F(R)F^*(R)\rangle_l = \sum_n J_n^2\,(2\pi Rr)|a_l^n|^2 \qquad (1a)$$

$$a_l^n = \sum_j \exp i\{-n\phi_j + 2\pi l z_j/c\} \qquad (1b)$$

where J_n is the *n*th order Bessel function, a_l^n the modulation term, and r, ϕ_j and z_j radial, azimuthal and axial coordinates of a molecule on the *j*th helix. In equation (1*a*), the effect of shape and size of a subunit on the intensity is not included. The summation in equation (1*a*) is taken over *n*, satisfying the selection rule[8] of $l = n + 2m$, where *m* is an integer. As $\Delta\phi = (1 - 1/14)\pi k$ and $\Delta z = c/28 \times k$, then $|a_l^n|^2 = 4\cos^2\{\pi k/28 \times (l+n)\}$ for l = even and $4\sin^2\{\pi k/28 \times (l+n)\}$ for l = odd. If $k = 1$ is assumed, even order Bessel terms would be dominant around the equator and $l = 28$, and odd orders would be dominant around $l = 13$ and 15 as shown in Fig. 3*c*, because modulation terms for meridional J_0 reflections (near-meridional $J_1 + J_{-1}$ reflections), for example, gradually vary with even (odd) values of *l*. If $k = 3$ is assumed, modulation terms vary three times faster with *l* (Fig. 3*d*).

In the actual resting pattern from the crab leg muscle (ref. 1 and Fig. 1*a*), (1) reflections are observed at every order from 2nd to 9th, except at 5th, (2) even order reflections have intensity maxima on the meridian whereas odd orders have not. These features are well explained only when $k = 1$. The presence of a meridional reflection at $l = 4$ and near-meridional one at $l = 9$ are hardly explained by $k = 3$. $k = 5$ and 7 are also excluded. The near meridional reflection at $l = 5$ may be buried in the strong reflection at 14.4 nm (assigned to thick filament). In the muscle in the resting state, the actin helix symmetry is slightly different from 28/13, and accordingly, the troponin helix is deformed slightly from 2/1. This difference is too small to affect the diffraction patterns[2]. We conclude that the troponin arrangement in Ohtsuki's model is valid for the thin filaments of the crab leg muscle, illustrating an application of this method in which intensity modulation is interpreted in terms of helical arrangement of molecules about the thin filament axis.

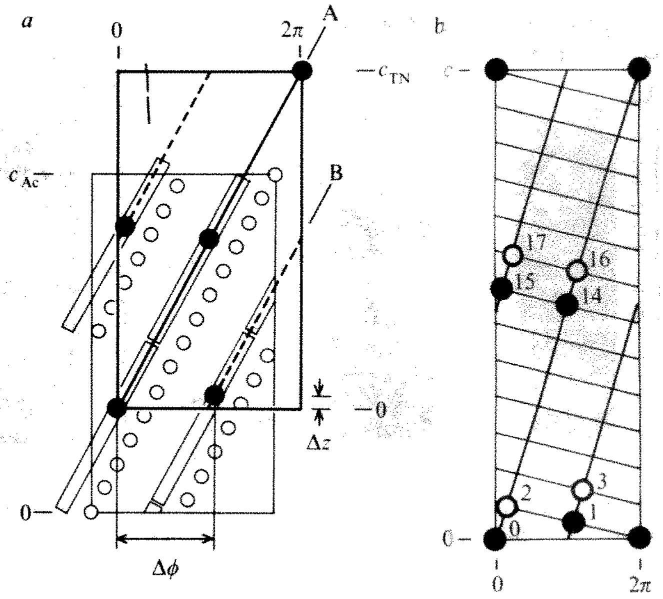

Fig. 2 *a*, The radial projection of the thin filament in Ohtsuki's model. A troponin molecule (closed circle) is attached to a specific site on a tropomyosin molecule (rectangular) which interacts specifically with seven actin subunits (open circles) arranged in a helix with the symmetry of 28/13 and the repeating distance of c_{Ac}. The arrangement of troponin molecules consists of two identical 2/1 helices, A and B, with the repeating distance of $c_{TN} = c_{Ac}$. Axial displacement (Δz) and azimuthal rotation ($\Delta\phi$) between two helices are specified by *k* multiples of those values between adjacent two actin subunits along the 28/13 actin helix, where *k* is an odd integer. Ohtsuki's model assumed $k = 1$. In the crab leg muscle[1], the symmetry of the actin helix is 28/13 in rigor, but in the living resting state it is between 26/12 (= 13/6) and 28/13. This means that the troponin helix differs slightly from 2/1 in the resting muscle. The solid frames represent one repeating unit of the structure. The shape of each molecule and the precise relationship between them are not shown. *b*, The radial projection of two possible models for the cross-bridge arrangement around the thin filament in crag leg muscle in rigor. When a pair of cross-bridges ($L = 1$) occurs symmetrically around the thin filament at intervals of 38 nm, four lattice points (closed circles) out of 28, labelled from 0 to 27 along the genetic helix, are occupied by cross-bridges. This arrangement is the same as the troponin arrangement shown in *a*($k = 1$). When two pairs ($L = 2$) of cross-bridges occur at positions adjacent to each other, four more sites (open circles) are occupied. In the latter case, the arrangement can be described by four identical 2/1 helices; each helix includes molecules labelled 0 and 14, 2 and 16, and so on.

If we assume that the head portions of myosin molecules are specifically attached to actin subunits, the surface lattice of cross-bridges around thin filaments in rigor (Fig. 2*b*) is the same as that of troponin molecules with $k = 1$, namely, cross-bridges occur in pairs at intervals of 38 nm. When another pair comes to the next position and both pairs are included at every 38-nm interval (Fig. 2*b*), the surface lattice can be described with four

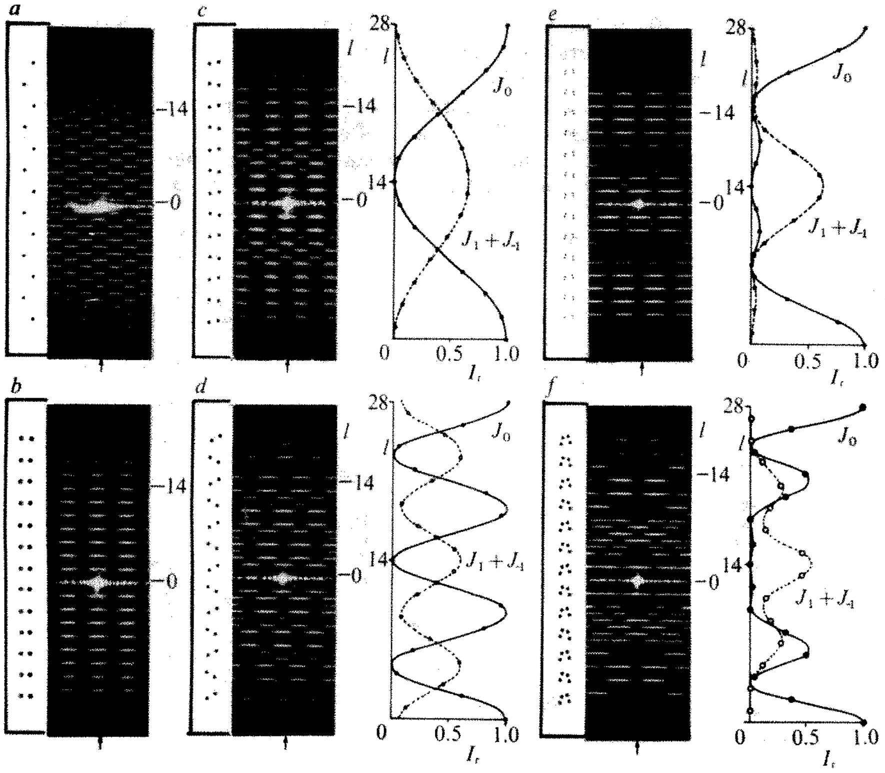

Fig. 3 Models of molecular arrangement around the thin filament and intensity modulations of diffraction patterns predicted from them. Models are *a*, single 2/1 helix; *b*, a pair of subunits in every 38 nm. The arrangement can be described with two identical helices with $\Delta z = 0$ and $\Delta\phi = 0$. *c*, The same as in Fig. 2*a*, *b* (closed circles only). The arrangement can be described with two identical 2/1 helices with $k = 1$. *d*, Two identical 2/1 helices with $k = 3$. *e*, The same as in Fig. 2*b* (closed circles plus open circles). *f*, Offer and Elliott model[10] for the arrangement of cross-bridges in insect flight muscle in rigor. In every 38 nm two pairs are attached to positions next but one to each other. In each set, the left is a model. Closed circles represent troponin and cross-bridges. The right of *a* and *b*, and the middle of *c*–*f* show optical diffraction patterns obtained from these models. To make higher order layer lines visible, the size of the circles in every model is chosen as that in *e*. The meridian is indicated by an arrow in each pattern. On the right in *c*–*f*, relative intensity maxima (I_r) of J_0 and J_1+J_{-1} contributions are plotted against l. These are calculated by equation (1), and the contribution of the form factor is neglected. In reality, unity in intensity in *e* and *f* is stronger by a factor of 4 than that in *c* and *d*. The necessary exposure time for the optical diffraction pattern in *a* is then 4 times as long as those in *b*, *c* and *d*, and 16 times as long as those in *e* and *f*. Note that if two molecules in pairs are axially aligned as in *b*, no odd order reflections can be observed. All the models are based on the actin helix of 28/13. Although the actin helix is slightly different in the crab leg muscle in the resting state, nevertheless, the difference is so small that the diffraction patterns are not affected[2].

identical 2/1 helices. When the number of pairs is increased to L, modulation terms, for example, for meridional J_0 reflections calculated by equation (1) are given as

$$|a_l^{n=0}|^2 = \sin^2(2L\pi l/28)/\sin^2(\pi l/28) \qquad (2)$$

which is an example of Laue function (Fig. 3*e*). Note that the more cross-bridges there are, the smaller the number of reflections on which intensities become concentrated. In the actual pattern from the crab leg muscle in rigor (ref. 1 and Fig. 1*b*), (1) meridional and near-meridional reflections were observed at orders from 2nd to 24th, of 76 nm; (2) meridional reflections at $l = 12$, 14 and 16 are absent, apparently due to a selection rule (if the form factor is diminished there, we cannot explain the fact that near-meridional components at $l = 13$ and 15 are observed in the actual pattern); (3) even order reflections have intensity maxima on the meridian, whereas odd order reflections have not. These features can be explained both by the model with $L = 1$ and by that with $L = 2$. In the diffraction pattern predicted from the $L = 2$ model, a few reflections (especially at $l = 2$) would be almost four times stronger and the rest would be weaker than in the $L = 1$ model. Nevertheless, we cannot decide between the two without measuring intensity distribution. Models with $L \geqq 3$ predict extinction of a meridional reflection at $l = 4$ in disagreement with the actual pattern. Any other model can be excluded. As we have pointed out[1], troponin molecules also contribute to these reflections. However, the result is not altered by the troponin contribution in this qualitative analysis of intensity modulation, as troponin does not make an important contribution to these intensities; the ratio of intensity of reflection in resting pattern to the corresponding one in the rigor pattern is smaller than 1/4 and higher order ($l > 9$) reflections are not observed in resting patterns.

To decide between the two possible models, and to determine the spatial relationship between troponin and cross-bridges on the same thin filament and also the size and shape of each molecule, we must make the analysis quantitative by obtaining a cylindrically symmetrical Patterson function[9].

Offer and Elliott[10] have proposed a model for the cross-bridge arrangement of insect flight muscle in rigor. In this model, two pairs of cross-bridges are included every 38 nm, but the second pair is positioned next but one to the first pair (Fig. 3*f*). The intensities predicted by the model, again based on intensity modulation calculated by equation (1), seem to be consistent with the recorded X-ray diffraction pattern[11]. In this muscle, the thin filaments are themselves arranged in a helical manner about the thick filament[12,13]. The absence of meridional reflections at $l = 2$ and 4 may be explained by the large helix. Lack of reflection at $l = 3$ might support the model, although other possibilities cannot be excluded. The disappearance of several near-meridional components of the diffraction pattern from the muscle after immersion in S-1 solution[3] could well be explained by the occurrence of more cross-bridges on the surface lattice with a symmetry of 28/13.

Vibert *et al.*[4] have recorded a series of reflections from scallop striated muscle in rigor which are thought to be similar to those from crab leg muscle in rigor. They observed an increase in intensities of near-meridional components at 38 nm and at 19 nm, after removal of the regulatory light chains. We might explain these observations by a rearrangement of the cross-bridges: from the arrangement with $L = 1$, for example, to that with $L = 2$. If this hypothesis is true, the intensities of some reflections would be decreased simultaneously.

I thank Professor F. Oosawa and Dr N. Sakabe for helpful comments on earlier drafts of this paper.

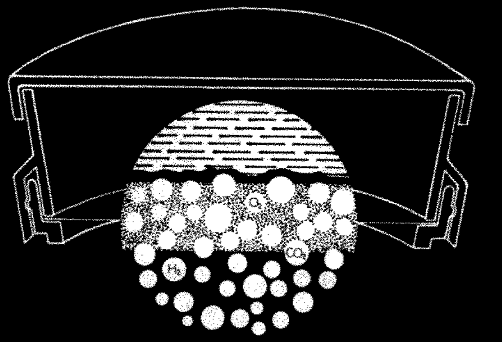
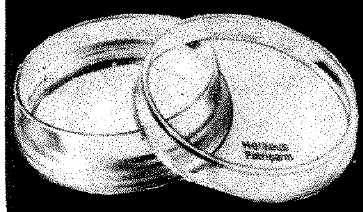
A new approach in tissue culture



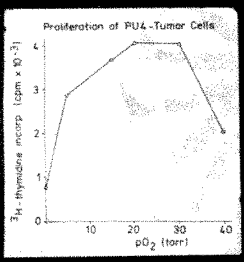


PETRIPERM
a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Heraeus—
CO_2-Incubator

Nature of chemical elements

G. N. Cantor

The Transcendental Part of Chemistry. By D. Knight. Pp. 289 (Dawson: Folkestone, UK, 1978.) £12.

CHEMISTRY, with all its associations with *praxis*, industry and sombre men in white coats, has or at least has had a 'transcendental' part as fascinating as that of any branch of physics. Yet the standard texts on the history of chemistry have all too often portrayed the development of their subject as an accumulation of experiments which lead directly to improvements in theory. By contrast this revisionist account, like some others of the genre, attempts to show both the subtle interplay between theory and experiment and the influence of metaphysical assumptions on both of these. In so doing Dr Knight and other recent historians of chemistry have uncovered some of the diverse intellectual roots of nineteenth-century chemistry.

This book concentrates on the theories of matter articulated by chemists and, in particular, their views about the nature of chemical elements. Two recurrent positions are identified: while some considered that the profusion of chemical substances were reducible to a very small number of fundamental types of particle—possibly even a single kind—though capable of many different arrangements, others adopted the view that each element was distinct and that it was the chemist's business to ascertain these, their properties and interactions. The relationship of these assumptions to practical chemistry is most clearly seen in the bitter dispute over the value of Prout's hypothesis. As Berzelius and others argued, experimental data refuted the hypothesis and thus seemed strongly to favour the latter position. However, the proponents of the former doctrine did not abandon the field but over a period of time made a strong comeback. The present book ends with Crooke's discovery of primary 'radiant matter' and, from the opposing party, Mendeleev's classification of the elements.

Much of the explicit history of chemistry discussed by Dr Knight is familiar terrain However, his interpretation of these events takes us far beyond the conventional bounds of chemistry. Matter theory is one of those areas influenced both by scientific and extra-scientific issues, and has thus provided a particularly interesting topic for historical analysis. For example, chemists of the early nineteenth century were able to draw on a stock of earlier theories such as those of Newton and his elaborators. Moreover, contemporary developments in many branches of science—such as electrochemistry, optics and heat theory—depended on and thereby affirmed certain current theories of matter. Finally, Dr Knight discusses the influences of theological, philosophical and other conceptual issues, citing evidence that some chemists conceived their matter theories as a bulwark against materialism and thus atheism.

The wide scope of this subject is both the book's strength and its weakness. The reader may at times lose the thread of the argument in moving rapidly from one topic to another and from the late eighteenth to the late nineteenth centuries. In very few cases do the specific relationships between metaphysics and practice emerge with the clarity which these complex issues deserve. Moreover, the philosophical underpinnings of matter theory—such as the definitions of 'matter', 'mechanism' and the role of analogy—deserve sustained analysis.

Despite these shortcomings Dr Knight has written a stimulating and enjoyable book which reflects the awareness among many historians that science has been influenced by extra-scientific factors and that a complex and intriguing relationship exists between metaphysical beliefs, scientific theory and experiment. ☐

G. N. Cantor is Lecturer in History and Philosophy of Science at the University of Leeds, UK.

Solid-state theory

Introduction to Solid State Theory. By O. Madelung. Pp. 486. (Springer: Berlin, Heidelberg and New York, 1978.) DM59; $29.50.

ONE might argue that solid-state physics is close to the point where the various parts are becoming so disparate and highly developed that there is no place for a relatively short (486 pages) graduate level account Professor Madelung's book on solid-state theory is intended for graduate students and research workers whose interests are primarily experimental, and provides a coverage of the main current theoretical ideas without using the formalism of modern many-body theory. He has produced a book which is small and coherent enough to be read in conjunction with a graduate course

The problem of writing a book of this sort is in the danger of either including discussions of a very wide range of subjects all of which are too brief to be useful; or concentrating on some aspects, and so giving an unbalanced account of the subject as a whole. The situation is complicated by the fact that there does not seem to be a consensus of opinion of what every solid-state experimenter should know. There are many obvious candidates such as, pseudo-potential theory, excitons, polarons, BCS theory of superconductivity, Boltzmann transport equation, the Hubbard Model, and so on. But equally there are many more subjects which may or may not deserve more than a passing mention; I would list here the Kondo effect, diffusion in ionic lattices, electron-hole recombination processes at imperfections, Anderson localisation (which Professor Madelung does include) and ferroelectricity and structural phase transitions, spin glasses, charge density waves, the Friedel sum rule and vitual bound states in metallic systems (which he does not). Everyone has his own list!

Pressing on with this argument one should ask: Is it a useful thing to try to do? Do we believe that an experimentalist concerned, say, with light scattering from magnetic insulators ought to know more than is present in the standard undergraduate textbooks on all, or any, of the topics I have mentioned? Also, how far is it useful to separate the theory of the behaviour of an isolated solid from the theory of the solid responding to some probe and if not which experiments should be included?

Professor Madelung believes that there are underlying themes in theoretical solid-state physics, and that this means that a study of one part of the subject is enriched by a knowledge of the rest. The primary theme that he has chosen is that of elementary excitations with a secondary theme of the dual descriptions of extended and localised states; and this has particular relevance to imperfect systems. The effects of uniform electric and magnetic fields have been included and most of the experiments which are discussed involve either absorption of light or simple transport properties.

The book uses the compact notation of second quantisation but calculations are performed using time-independent perturbation theory. This has the advantage that the new physical ideas are not obscured by unfamiliar formalism. There is a useful list of problems and topics for discussion to help the student assimilate the material. A further strength of the book is its excellent bibliography which includes a large number of review articles as well as books and original papers.

I find myself convinced that there is a place for a book of this length at this level and would recommend Professor Madelung's book, particularly to new graduate students.

G. A. Gehring is the Physics Tutor at St Hugh's College, and a Lecturer in the Department of Theoretical Physics at the University of Oxford, UK.

Psychopharmacology handbook

Handbook of Psychopharmacology Edited by L. L. Iversen, S. D. Iversen and S. H. Snyder. Vol. 7: Principles of Behavioral Pharmacology. Pp. 453. $41.40 Vol. 8: Drugs, Neurotransmitters, and Behavior. Pp. 590. $47.40. Vol. 9: Chemical Pathways in the Brain. Pp. 410. $35.40. (Plenum: New York and London, 1978.)

WITH these three volumes the Iversen–Snyder *Handbook* moves from the field of basic neuropharmacology into behavioural pharmacology. A total of 30 chapters contributed by 47 authors encompasses a range of subjects from the analysis of operant schedules (Dews and de Weese) to the localisation of gabaminergic neurones (Fonnum and Storm-Mathisen). The contributions are of a high standard and many are highly readable, but it is inevitable in an undertaking of this size that their relationship one to another is often uncertain Thus, each author attempts to produce a major review of his topic, but is bound to cover material which is also included elsewhere either in these or earlier volumes. Handbooks (and Handbücher) have always suffered from this problem, but of the genre the Iversen–Snyder production has much to commend it. In few other places can one find so much information relevant to the discipline.

Psychopharmacology is nothing if not cross-disciplinary. This should be most evident where two well established disciplines—for example, Psychology and Pharmacology—meet, as they do in volume 7 (Principles of Behavioral Pharmacology). It is interesting to see the extent to which one field has influenced the other In some cases the impact seems to have been small In the Dews and De Weese review referred to above drugs appear as another environmental variable to be accommodated by the same Skinnerian framework that describes other aspects of behaviour. The fact that such agents may be acting upon specific chemical mechanisms within the brain, and that these mechanisms may be regulating specific aspects of behaviour, is regarded as irrelevant to the description of drug action. The purely inductive approach seems, in this case, to act as a defence against asking some obvious, if difficult, questions. From a different psychological viewpoint Milner demonstrates a similar insularity. In giving a useful introductory survey to theories of motivation and learning which would be at home in a textbook of psychology, followed by some neural models, Milner implies that all this may be relevant to recent work on the physiology of central monoamine systems. Yet when it comes to making specific predictions from his own theory, or assessing the progress of other theories of the functions of monoamine neurones, Milner is reticent. It is at this point that the discipline of psychopharmacology (if there is one) gets interesting.

By contrast the work reviewed by Marshall and Teitelbaum (Neuropsychology of Motivated Behaviours) reveals the contribution which a rigorous application of the techniques of neuropsychology to preparations derived from advances in neuropharmacology (6-hydroxy-dopamine induced lesions of dopamine neurones) can make to our understanding of the mechanisms of behaviour. The theoretical implications of this work are considerable, though not developed at length by these authors, and give support to the view that neuroscience is in some respects leaving psychology behind. Other chapters in this volume cover major technical questions (for example, Robbins on motor activity, Mackintosh and others on ethological contributions and methods). Kumar has contributed a succinct but wide-ranging review of animal models of relevance to psychiatry, attempting to synthesise psychodynamic (for example, object loss), ethological, operant (for example, learned helplessness) and neuropharmacological, hypotheses. New dimensions to psychopharmacology are reviewed by Broadhurst (genetics) and Mabry and Campbell (development)

Many issues in volume 7 re-appear in volume 8 (Drugs, Neurotransmitters and Behavior), sometimes in a more controversial form. Here major motivated behaviours (eating, drinking, sleep) or motivational constructs (reward, punishment, fear, frustration) are foci for a discussion of pharmacological, behavioural and often many other aspects. Sometimes the relevance for psychopharmacology is obscure. For example, in a somewhat partisan account of the anatomy of self-stimulation, Routtenberg and Santos-Anderson make a virtue of discounting the neuropharmacological interest of the reward phenomenon. To this reviewer it remains an interesting and viable hypothesis that all reward

Applied group theory

Induced Representations in Crystals and Molecules: Point, Space and Non-rigid Molecule Groups. By S. L. Altmann. Pp. 369. (Academic: London, New York and San Francisco, 1978.) £18; $32 25. Review by H. C. Longuet-Higgins, *Nature*, **274**, 403 (1978).

DR ALTMANN has drawn the Editor's attention to certain sentences in Professor Longuet-Higgins' review, which he believes are open to criticism.

Professor Longuet-Higgins now writes:

First, my remark that Dr Altmann's groups are "virtually useless for classifying the rotational levels of non-rigid molecules" might have ben misconstrued to imply that the book deals explicitly with rotational levels. This it does not do, nor does it claim to do so, although Dr Altmann does give reference to theoretical work which is relevant to the treatment of rotational levels.

Secondly, the statement in the review that the symmetry operations relevant to an overall molecular state must "commute with the full molecular hamiltonian" could be taken to imply that the book defines symmetry operations to commute only with the Born–Oppenheimer hamiltonian; that is not the case.

Finally, my statement that "the book is, unfortunately, riddled with misprints . . . spelling mistakes ." could be read as suggesting that such errors were numerous. In fact I found very few.

I apologise unreservedly to Dr Altmann for having allowed these matters to escape my attention

H. C. Longuet-Higgins

New books from CAMBRIDGE

Case Studies in Genetics

M. A. TRIBE, I. TALLAN and M. R. ERAUT

An introduction to genetics, in which many of the fundamental concepts are presented through a series of well researched case studies; prominence is given to human genetics. Although aimed at first year undergraduates, the book could be used by able sixth formers with a knowledge of biology above 'O' level. It has been designed assuming a knowledge of cell division, elementary genetics and protein synthesis as given in Books 3 and 9 of the Basic Biology Course. This book follows the self-instructional format of the others in the series. As well as the questions within the text, there is an extensive array of self-assessment questions at the end of the book, as well as a comprehensive glossary of terms.

Basic Biology Course 12 **Hard covers £9.50 net**
Limp bound £3.95 net

An Analysis of Primary Medical Care

W. J. STEPHEN

This volume examines the provision of primary medical care in twenty-three different countries, selected because of their variety and importance. The underlying thesis of the account is that the health of any population depends more on the availability of good primary health care than on the advanced technology and sophistication of modern hospitals. The reasons why resources have been allocated in a way that does not reflect this view are argued fully. Note is also taken of the fact that medicine and politics have become interwoven in most countries of the world. **£12.50 net**

Uniform Algebras and Jensen Measures

T. W. GAMELIN

These lecture notes are devoted to an area of current research interest that bridges functional analysis and function theory. The topics covered include the rudiments of Choquet theory, various classes of representing measures, the duality between abstract subharmonic functions and Jensen measures, applications to problems of approximation of plurisubharmonic functions of several complex variables, and Cole's theory of estimates for conjugate functions. Many of the results, including Cole's theory, are published here for the first time.

London Mathematical Society Lecture Note Series 32 **Limp bound £6.50 net**

Mechanical Behaviour of Ceramics

R. W. DAVIDGE

This book presents the scientific foundations of the mechanical behaviour of ceramics and demonstrates how these can be used in engineering situations. The emphasis is on principles, illustrated by a careful selection of experimental data. The treatment is at a level suitable for undergraduate and graduate students on materials-oriented courses and for research and development workers involved in engineering applications of ceramics.

Cambridge Solid State Science Series **£15.00 net**

The Enzyme Game

D. PEACOCK and M. A. TRIBE

This book is a simulated research exercise concerned with identifying the structure and mechanism of action of an unidentified enzyme. Its aim is to provide students with the opportunity of working collaboratively in small groups to discuss and develop a research programme. The game is ideally suited for teaching students taking courses in the biological sciences in universities, colleges of education, polytechnics and sixth forms in schools.

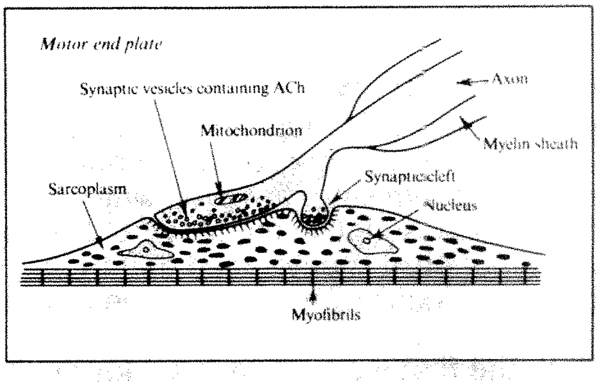
Basic Biology Course **Limp Bound £15.00 net**

Grassland Ecosystems of the World

Edited by R. T. COUPLAND

This volume describes the structure and functioning of grassland ecosystems. Descriptions of the abundance and biomass of plants, animals and microorganisms are provided, as well as an assessment of the activities of each functional group of organisms in relation to production, consumption and decomposition. Static models of energy flow and nutrient cycling are included, and the effects on the ecosystem of the management of grazing land and cropland are also considered. This book is a companion to the forthcoming BP 19, *Grasslands, Systems Analysis and Man*, each representing an independent approach to the problems of studying grasslands.

International Biological Programme 18 **£25.00 net**



Mechanisms of Drug Action on the Nervous System

R. W. RYALL

Drugs affecting the peripheral nervous system and the brain are among the most widely used in contemporary medicine. This book analyses currently available information on the therapeutic or toxic effects of drugs in relation to the underlying physiological processes and pathological phenomena. It attempts to fill the gap between the many excellent textbooks of therapeutics and the highly specialised research reviews and monographs. The book is aimed principally at undergraduate students in the natural and medical sciences, and is the first in a new series.

Announcing a major new journal

Marine Biology Letters

CALL FOR PAPERS

Editors-in-Chief: D.J. CRISP, N.E.R.C. Marine Invertebrate Biology Unit, University College of North Wales, Bangor, LL57 2DG, Wales, U.K. and R.K. KOEHN, Department of Ecology and Evolution, Division of Biological Sciences, State University of New York, at Stonybrook, 11794, U.S.A.

Aims and Scope

The journal will provide a medium for the rapid publication of essentially short, definitive articles on marine organisms, which are broadly concerned with biophysical, biochemical and physiological processes as they affect the individual or the population.

Specific areas to be included are:- sensory and motor neural mechanisms; respiratory physiology and energy metabolism; aspects of nutrition and reproduction; homeostatic mechanisms and hormonal control; experimental embryology and cytology; biochemical and population genetics. Articles on multidisciplinary studies will also be considered and occasional reviews will be published following invitation by the Editors-in-Chief.

Editorial Policy

Marine Biology Letters will not be an appropriate medium for purely descriptive papers such as works on descriptive morphology, descriptive ecology or natural product chemistry. However, where the main purpose is to analyse or explain function, descriptive matter would not be excluded if it formed an integral part of the contribution. It is envisaged that the average paper will be in the region of 6-8 printed pages in length, but papers will not be rejected on account of brevity.

With the first issue scheduled for publication in July 1979, MARINE BIOLOGY LETTERS will become a vital forum for the rapid and constructive exchange of ideas and developments, providing researchers with a unique opportunity to keep abreast of advances in the area.

1979 Volume 1 in 6 issues,

signals are channelled through a final catecholamine element (whether dopaminergic or noradrenergic); whether or not this turns out to be the case it is the association of reward pathways with specific neurohumoural mechanism that must be of particular interest to the psychopharmacologist.

The balance is to some extent redressed by the discussion of Stein *et al.* of the neuropharmacology of reward and punishment. Noradrenaline features prominently, as expected, in relation to the former function, but dopamine now also has a place. The increasingly cogent evidence for a relationship between 5-hydroxytryptamine and punishment mechanisms, and their possible relevance to the actions of the benzodiazepines, is also reviewed. Diverse neuropharmacological approaches to feeding (Hoebel), drinking (Setler) and reproductive behaviour (Meyerson and Eliasson) are comprehensively handled, but many conceptual problems remain. In Jouvet's account of the current state of research on the neurohumoural mechanisms of sleep and waking it is apparent that much that earlier seemed to be clear on the basis of short-term experiments becomes obscure when the ability of the brain in the long term to compensate to apparently decisive insults is revealed.

This volume ends with provocative chapters by Gray on fear and frustration, and Hunter *et al.* on learning and memory. Gray believes that nonreward, punishment and novelty are classes of stimuli that have characteristics in common and may act by a single neurohumoural mechanism. His view that this includes the locus coeruleus projection to septum and hippocampus is in interesting contrast to the views of Stein and others expressed earlier in the volume. Hunter *et al.* review the evidence that noradrenaline and perhaps also 5-hydroxytryptamine and acetylcholine, may be directly involved in the acquisition and storage of new information.

In volume 9 the series returns from the knotty problems of correlating anything with behaviour to the more certain but rapidly expanding field of neurotransmitter pathway mapping. Here the juxtaposition of a number of reviews will be invaluable to the worker who wants a comprehensive account.

The *Handbook of Psychopharmacology* invites comparison with *Psychopharmacology: A Review of Progress 1957–1967* (ed. D. H. Efron, P.H.S. Publication 1836, US Government Printing Office, Washington, 1968) and its successor *Psychopharmacology: A Generation of Progress* (ed. M. A. Lipton, A. D. Di Mascio and K. K. Killam; Raven: New York, 1978). Both the *Handbook* and its competitors are good value. Reviews are presented in more detail, particularly with respect to techniques and their difficulties, in the *Handbook*. Therefore for a shorter review of an aspect with which he is unfamiliar, and particularly with viewpoints and theories, the reader may be advised to go the "Progress" volumes. For a more detailed account the *Handbook* presents much information in a readable form.

Metal ion solvation

Metal Ions in Solution. By J. Burgess. Pp. 481. (Wiley: New York, London and Toronto, 1978.) £25; $55.

As implied by the absence of the word "complex" from the title, this book is not concerned with metal complex ions in general. The author has wisely chosen to focus attention on the properties and certain reactions of metal ions that contain one or more solvent molecules as ligands. In view of the abundance of the present literature on inorganic solution chemistry, this is enough for any man to attempt. The result is a book that brings together in convenient form a wide variety of topics which are discussed in sufficient depth to provide a grasp of essentials and a stimulation to further study.

About two-thirds of the book deals with the study of metal ion solvation by spectroscopic and other techniques, thermodynamic aspects (thermochemistry and redox potentials), hydrolysis and polymerisation. The remaining third is concerned with kinetics and mechanisms—solvent exchange, anation reactions, redox reactions, and reactions of coordinated solvents. The solvolysis and stability constants of complexes are not covered. The treatment of aqueous systems necessarily forms a major part of the discussion, but there are frequent references throughout to non-aqueous solvents and a chapter on mixed solvents and selective solvation. Each topic is introduced at a level that requires a knowledge of basic physical chemistry and then progresses rapidly to the edge of the research literature.

The book is well organised, as shown by the extensive table of contents, and well documented with over 1,700 references and nearly 200 tables of

Vincent J. Maglio & H. B. S. Cooke
The Evolution of African Mammals
Current knowledge about the origin and evolution of the Class Mammalia in Africa is summarised in this book. The major geological deposits of the African Cenozoic are reviewed and the broader patterns of faunal evolution are identified. The modern mammalian fauna and environments are discussed, as is man's impact on wildlife. 77 line drawings, 66 halftones, bibliographies. February 1979, £42.00.

Geerat J. Vermeij
Biogeography and Adaptation
Patterns of Marine Life
Through this discussion of evolutionary process and adaptive response, Vermeij elucidates the general principles that underlie the great diversity of marine forms found in the world's oceans. 81 halftones, 9 line drawings. February 1979, £17.50.

B. Raymond Fink and Robert J. Demarest
Laryngeal Biomechanics
Fink and Demarest offer a new model of laryngeal function and provide both an atlas and a treatise of the behaviour of the larynx, for its size the most complex and versatile mechanical device in the body. Commonwealth Fund, 69 halftones, 26 line drawings. January 1979, £21.00.

H. J. Phaff, J. W. Miller & E. M. Mrak
The Life of Yeasts
2nd edition, revised & enlarged
The second edition of this book covers recent and major advances in knowledge of the morphology, physiology, genetics and ecology of yeasts, increasingly studied as prototypical eukaryotes. 15 line drawings, 13 halftones. January 1979, £10.50.

Circle No. 14 on Reader Enquiry Card.

data. The text is set out clearly and seems to be almost entirely free of misprints. There are a few criticisms, of course, but these arise mainly from personal prejudice as to the best way of teaching a particular topic and are perhaps most appropriately aired by direct communication with the author. According to the author the book is intended to occupy the middle ground between the elementary textbook and the erudite review. This is a fair claim. The enterprising undergraduate will find much of use and interest but, considering all the other parts of chemistry to be studied, will probably find the price beyond his means. Teachers will find the basis for courses at various levels in some important areas where inorganic and physical chemistry overlap. Research workers will find the necessary background (up to the end of 1975) to topics that border on their main fields of interest. There is something for everyone here. **J. S. Coe**

J. S. Coe is Senior Lecturer in the Department of Chemistry, King's College, University of London, UK.

Aspects of the nude mouse

The Nude Mouse in Experimental and Clinical Research. Edited by J. Fogh and B. C. Giovanella. Pp. 502. (Academic: New York and London, 1978.) $31; £20.15.

THE most provocative sentence in this interesting book is written by Rygaard. "If the nude mouse had appeared a decade earlier probably nobody would have paid any attention to the odd animal. Had it appeared a decade later most of the problems to which it may offer a solution would have been solved by other means". The last point is surely wrong, The congenitally athymic, nude mouse has been useful in confirming solutions that had been fairly well established using the less perfect T lymphocyte-deficient animals that immunologists have strived so hard to improve but the real value and fascination of this mutant arise from the new problems it has suggested. Thus the appearance of the *nu* gene would have stimulated a flurry of activity had it appeared at any time in the foreseeable future. Immunologists have achieved solutions to some of their problems but the strength of the subject lies in the number of soluble problems on our plate.

This is a timely, useful and well organised collection of chapters on many aspects of the nude mouse. The authors can be cleanly divided into those who regard the nude as a self-replenishing (although hopelessly complicated) test tube for sustaining human tumours, and those who exploit the nude to clarify the mechanisms by which normal and nude mice sometimes resist infection, grafts of foreign tissue and tumours. It is clear that the nude mouse reared under conventional conditions is near perfect in its incapacity to reject by an immune response grafts from other strains or from other species as distant as birds and reptiles. However nude mice do not in general show a higher incidence of either spontaneous or induced tumours. Rygaard and Povlsen found no tumours in a series of nudes observed for 5,600 years of mouse life. According to Stutman's thoughtful analysis the *nu* gene has probably no influence on the incidence of tumours: nudes seem to develop tumours less frequently than other mice because they are usually dead before they are six months old. Of all the observations in disagreement with the doctrine of immune surveillance this is the easiest to grasp. The T cell system of cell-mediated immunity is of established value in defence against infection and so it is unnecessary to search for additional advantages such as the infanticide of tumours.

If it is not done by T cells do animals use another system for stifling tumours and is this enhanced in the nude mouse? Here and elsewhere a great deal is written about NK cells—apparently lymphocytes possessing Fc receptors which kill a certain range of tumour cells *in vitro*. One is left convinced that the NK cell will come to be regarded as either the major immunological discovery of this decade or as a remarkable fiasco.

The ingenuity applied to the exploitation of the nude mouse is only just beginning. Two separate strains of nude, athymic rats have recently been discovered. These may or may not share precisely the same genetic defect with each other and with the nude mouse. In their turn they will confirm much of the new information gleaned from the nude mouse and will suggest fresh problems of their own.

W. L. Ford

W. L. Ford is Professor of Experimental Pathology at the University of Manchester, UK.

Catalytic processes

Chemistry of Catalytic Processes. By B. C. Gates, J. R. Katzer and G. C. A. Schuit. Pp. 464. (McGraw-Hill: New York, London and Toronto, 1978.) £21.35.

THIS is an interesting book which brings together the chemistry of catalysis and many of the concepts and techniques of importance to the operation of processes on the industrial scale. The plan adopted is to cover just five of the most significant types of catalytic processes and use them as a framework upon which to build. This approach might give the impression that the treatment of the subject would be more specialised and less general than is appropriate for a book of this kind, but, in fact, such an impression would be completely false. A great deal of fundamental chemistry is introduced as a basis for discussion of the chosen processes

The chapter on cracking provides an account of catalysis on amorphous and crystalline acidic surfaces, describes the chemistry associated with carbonium ion intermediates and in addition it covers aspects of reactor design needed for catalyst regeneration to avoid loss of activity from coking The second chapter is concerned with a number of reactions on transition metal complexes falling mainly under the classification of homogeneous catalysis; the basic chemistry included in this chapter deals with structure, bonding and reactions of organometallic complexes.

There is a very substantial amount of relevant fundamental material in the chapter on reforming. The treatment ranges from discussions of bonding in metals and alloys to consideration of the structures of typical oxide supports and from evidence for the nature of hydrogen adsorption on clean surfaces to the mechanisms of various hydrocarbon reactions on metals and on alumina.

The final chapters cover oxidation as exemplified by the ammoxidation of propylene and hydrodesulfurisation. Once again the same general combination of fundamental chemistry with relevant process engineering is provided in these chapters.

Taken as a whole this is a stimulating book which should appeal to a wide range of chemists and engineers who have a concern with reactions on surfaces. The novel approach and the skilful blend of recent ideas and developments with the more traditional aspects of the subject make the volume both attractive and timely.

Charles Kemball

Charles Kemball is Professor of Chemistry at the University of Edinburgh, Scotland.

Synopses of the British Fauna (New Series) edited by Doris M. Kermack and R. S. K. Barnes **No. 13**

British and Other Phoronids

C. C. Emig

March/April 1979, vi + 58pp., £2.80/$5.75 0.12.238750.3

Phoronids are a small, but widely distributed, group of benthic marine animals. The author provides keys and descriptions to enable not only the British species to be identified but also all other known species. This book, which is based on research over the last 20 years is the most recent review of the life history of phoronids and their morphological and anatomical characteristics. This synopsis includes full descriptions of species of phoronids occurring outside British waters.

The Soil-Root Interface

Proceedings of an International Symposium and published under the aegis of the New Phytologist

edited by J. L. Harley and R. Scott-Russell

March/April 1979, xx + 448pp., £15.40/$31.75 0.12.325550.3

While some aspects of the interactions between plant roots and the soil have been investigated for a century or more, there are others about which, very little was known until recently. The growth of interest in this field of research has to a large extent been due to the development of new experimental techniques which have permitted the examination of the more complex factors of water supply, nutrient availability and the pathology of plants. The specialized knowledge required for these studies necessitates a multi-disciplinary approach and those involved felt that there was a need to meet to discuss ideas and recent progress in the physical, chemical, biochemical, biological and microbiological characteristics of the interfacial region. This volume is the outcome of that meeting, which was held in Oxford in March 1978.

Studies of Language, Thought and Verbal Communication

edited by R. M. Blakar and R. Rommetveit

February/March 1979, approx. 500pp., £22.40/$47.25 0.12.594660.0

This book covers nearly two decades of theoretical and empirical inquiries into language, thought and human communication. A wide range of substantial issues is covered in the volume: from micro-analysis of the process of reading to patterns of communication in families containing schizophrenic members; and from contractual aspects of communication to analysis of language as a means of social power. Eight papers in Section 1 examine dominant traditions within research on language, thought and communication and outline an alternative conceptual framework. Section II follows with twenty-seven papers giving empirical support to this alternative social-cognitive framework.

An Introduction to Quarks and Partons

F. E. Close

March/April 1979, xiv + 472pp., £26.40/$54.50 0.12.175150.3

High Energy Physics has experienced a renaissance during the last four years, and the significance of quarks has become universally recognised. Since the excitement generated by recent discoveries such as that of the psi particle in 1974, and subsequently of 'charm', there has been no major *book* — as opposed to summer school reports — to cover progress in the rapidly developing field of High Energy Physics. This graduate text aims to correct this situation by presenting the basic ideas on quarks and partons at a level that can be understood by theorists and experimentalists with some familiarity with elementary particle physics or, simply, quantum mechanics. After this grounding, and with the aid of the comprehensive bibliography, the reader should be able to investigate the subject to whatever depth he chooses.

Annual Reports on NMR Spectroscopy Volume 8

edited by G. A. Webb

March/April 1979, x + 380pp., £28.00/$58.00 0.12.505308.8

The major aim of this widely-acclaimed series is to provide timely accounts of those areas of NMR spectroscopy where significant advances are being made. In recent years the advent of FT—NMR techniques has shifted the emphasis away from proton NMR towards less receptive nuclei such as 13c and 15N which are now being studied routinely in many laboratories. This, and recent progress in the theoretical interpretation of NMR parameters, is reflected in this series which covers NMR applications in all branches of science.

COMING SHORTLY!

JOURNAL OF NEUROSCIENCE METHODS

Editor-in-Chief
J. S. KELLY, MRC Neurochemical Pharmacology Unit, Department of Pharmacology, Medical School, Hills Road, CAMBRIDGE CB2 2QD, U.K.

Associate Editors
V. E. DIONNE, Burlington, VT., U.S.A. **E. G. MERRILL,** London, U.K. **F. VANDESANDE,** Ghent, Belgium.

Aims and Scope

The **JOURNAL OF NEUROSCIENCE METHODS** publishes research papers and a limited number of broad and critical reviews dealing with new methods or significant developments of recognised methods used to investigate the organisation and fine structure, biochemistry, histo- and cytochemistry, physiology, biophysics and pharmacology of: receptors, neurones, synapses and glial cells, in the nervous system of man, vertebrates and invertebrates. These studies may also be applicable to the clinical and behavioural sciences, tissue culture, neurocommunications, biocybernetics or computer software.

Although articles should be written in sufficient detail to allow others to verify these methods, they should also be intelligible to a broad scientific audience.
In addition, the journal publishes letters sent in camera-ready format, on paper supplied by the editorial office, containing comments or discussion of methodology described in this journal or any other journal devoted to the neurosciences.

R. E. Zigmond, Cambridge, MA., U.S.A.

The following is a selection of papers appearing in initial issues. (First issue due March 1979)
A critical review of immunocytochemical methods for light microscopy *F. Vandesande (Ghent, Belgium)*
Techniques for precision beveling of relatively large micropipettes *K. T. Brown and D. G. Flaming San Francisco, Calif., U.S.A.)*
Photoelectrode with a very short time-constant for recording intracerebrally Ca^{2+} transients at a cellular level *E. Labeyrie and Y. Koechlin (Paris, France)*
Stereotaxic electrode placement in the neonate rat *A. Heller, J. G. Hutchens, M. L. Kirby, F. P. Karapas and C. Fernandez (Chicago, Ill., U.S.A.)*
Computer-assisted mapping with the light microscope *D. J. Forbes and R. W. Petry (Duluth, Minn., U.S.A.)*
A new moving-coil microelectrode puller *D. R. Ensor (Edinburgh, Scotland)*
Immunoglobulin elusion from multiple-sclerosis brain *D. H. Gilden and T. Tachovsky (Philadelphia, Pa., U.S.A.)*
A method of reversible inactivation of small regions of brain tissue. *J. G. Malpeli and P. H. Schiller (Champagne, Il., U.S.A. and Cambridge, Mass., U.S.A.)*

announcements

Awards

The Royal Society has recently awarded the following medals: The Copley Medal to **Professor R. B. Woodward**; Royal Medals to **Professors R. A. Gregory, A. Salaam** and **T. Kilburn**; The Davy Medal to **Professor A. Eschenmoser**; The Darwin Medal to **Dr G. Pontecorvo**; The Leverhulme Medal to **Sir Frederick Warner**; The Mullard Medal to **Dr J. W. Black**; The Esso Medal to **A. G. Frame, J. M. Laithwaite, A. D. Evans, Dr J. F. W. Bishop** and **Dr T. N. Marsham**; The Rumford Medal to **Sir George Porter**; The Hughes Medal to **Professor W. Cochran.**

The following awards of the New York Academy of Science were made recently: The Distinguished Service Award of The New York Academy of Sciences was presented posthumously to **Margaret Mead,** eminent anthropologist and humanist, in recognition of her outstanding contributions to science and society; **Harrison Brown** has received The New York Academy of Sciences Award; **Anna Goldfeder** has received the Academy's Presidential Award; **Philip Leder** has received The New York Academy of Sciences Award in Biological and Medical Sciences. **Michael E. Fisher** has received The New York Academy of Sciences Award in Physical and Mathematical Sciences; **Michael Cole** has received The New York Academy of Sciences Award in Behavioral Sciences; **Peter Rentzepis** has received the A. Cressy Morrison Award in the Natural Sciences; **John J. McKetta** has received The Boris Pregel Award for Applied Science and Technology; **Paul Edward Garber** has received the I. B. Laskowitz Award for Research in Aerospace Engineering Sciences, Support Systems and Components; **Barbara McClintock** has received the Louis and Bert Freedman Foundation Award for Research in Biochemistry; **Victor Sidel** has received the Sarah L. Poiley Memorial Award; **Patrick Eggena** has received the Dr Harold Lamport Award; **Orville L. Chapman** has received the Gregory and Freda Halpern Award in Photochemistry.

Professor J. H. Burn, Emeritus Professor of Pharmacology, Oxford University, has been awarded the first Wellcome Gold Medal of the British Pharmacological Society.

The 1979 Israel Prize in the Life Sciences has been awarded to **Professor Hans Lindner,** Head of the Weizmann Institute's Hormone Research Department, for his outstanding achievements and most important contributions to endocrinology and the biology of reproduction.

The American Geophysical Union (AGU) has presented **Hsieh W. Shen,** Professor of Civil Engineering, Colorado State University, with the Robert E. Horton Award.

The first Wellcome Trust Award for Research in Biochemistry Related to Medicine has been made to **Dr D. J. H. Brock,** Reader in Human Genetics in the University of Edinburgh.

R. W. Whorlow, Senior Lecturer in the University of Surrey's Department of Physics, has received the first Annual Award of the British Society of Rheology, in recognition of his outstanding services to the Society for his work in the teaching and science of rheology.

Appointments

The President of the Royal Society, the Rt. Hon. the Lord Todd, OM, has appointed the following Vice-Presidents for the year ending 30 November 1979: **Dr B. J. Mason, CB,** Treasurer of the Royal Society; director-general of the Meteorological Office; **Professor D. C. Phillips,** Biological Secretary of the Royal Society; professor of molecular biophysics at the University of Oxford; **Dr T. M. Sugden, CBE,** Physical Secretary of the Royal Society; master of Trinity Hall, Cambridge; **Dr M. G. P. Stoker, CBE,** Foreign Secretary of the Royal Society; director of the Imperial Cancer Research Fund Laboratories; **Professor P. Allen,** professor and head of the department of geology and director of the sedimentology research laboratory in the University of Reading; **Sir Arnold Hall,** chairman and managing director, Hawker Siddeley Group Limited; **Professor D. C. Smith,** Melville Wills professor of botany and director of biological sciences in the University of Bristol; **Sir Michael Woodruff,** emeritus professor of surgery in the University of Edinburgh.

Professor Dennis J. Greenland has been appointed Deputy Director-General of the International Rice Research Institute in the Philippines.

Tony Benn, Secretary of State for Energy, has appointed **W. P. Blair** to be a member of the Advisory Council on Energy Conservation. Mr Blair is an Executive Council member of the Electrical, Electronic, Telecommunications and Plumbing Union (EETPU).

Dr Page Faulk, formerly Director of the Division of Developmental Immunology to The Medical University of South Carolina, US, has been appointed as Director of The Blond McIndoe Centre with effect from the 1st January 1979 and the Royal College of Surgeons of England have conferred on him the title of Honorary Research Professor.

Dr Charles M. Brown, senior lecturer in Biological Sciences at the University of Dundee, has been appointed to a new Chair in the Department of Brewing and Biological Sciences at Heriot-Watt University, Edinburgh. He will take up his appointment on 1 July 1979.

On 1 July 1979, **Dr Daniel A. Pollen** will become Director of Neurological Research and Chairman of the Division of Neurobiology at the Barrow Neurological Institute of St Joseph's Hospital and Medical Center in Phoenix, Arizona. Dr Pollen leaves the Neurosurgical Service of the Massachusetts General Hospital and Harvard Medical School where he was Associate Professor of Physiology in the Department of Surgery.

Dr J. W. Bridges, Reader in the University of Surrey's Department of Biochemistry and Director of the recently founded Institute of Industrial and Environmental Health and Safety, has been appointed to the new Chair in Toxicology—the only University Chair in Toxicology in the UK.

Joel L. Lebowitz, Professor of Mathematics and Physics and Director of the Center for Mathematical Sciences Research at Rutgers University, has been installed as president at The New York Academy of Sciences' 161st Annual Meeting held at The American Museum of Natural History on 5 December 1979.

Edward R. Hitchcock, a Birmingham medical graduate of 1952, has returned to the University as Professor and Head of the Department of Neurosurgery.

The Trustees of the Nuffield Foundation have approved a scheme devised by the Foundation's Committee on Rheumatism Research for the appointment of Senior Visiting Fellows in Rheumatism Research. The Committee hopes that the first appointment under this scheme will be made in time for the beginning of the academic year 1979–80. These Fellows will normally be based at a suitable laboratory in the UK during the tenure of their fellowship, but will be expected to visit most other centres of rheumatism research in Britain during the period of their appointment. Correspondence should be addressed to John Maddox, Director of the Nuffield Foundation, Nuffield Lodge, Regents Park, London NW1.

Meetings

2–6 April, **Appropriate Energy Technology for Development**, Glasgow (Dr J. Twidell, Appropriate Technology Seminar, Dept. of Applied Physics, University of Strathclyde, Glasgow, UK).

3–5 April, **Analytical Symposia**, London (T. Goodall, Pye Unicam Ltd, York Street, Cambridge, UK).

4–6 April, **Cell Adhesion and Motility**, Glasgow (Dr J. D. Pitts, Dept of Biochemistry, University of Glasgow, UK).

18–20 April, **ELSE, 4th General Assembly**, Budapest (Miss N. Morris, 30 Longdown Road, Lower Bourne, Farnham, Surrey, UK).

19–20 April, **Superconducting Electrical Machines**, Oxford (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

15 May, **Cancer—The Patient**, London (The Secretary, The Marie Curie Memorial Foundation, 124 Sloane Street, London SW1, UK).

16 May, **Industrial Applications of Particle Beams for Materials Analysis**, London (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

16–17 May, **32 Chemists' Conference**, Scarborough (K. Speight, British Steel Corporation, Sheffield Laboratories, Hoyle Street, Sheffield, UK).

2–13 July, **Factors Influencing Urban Design: A Systems Approach**, Louvain-la-Neuve (Dr P. Laconte, Expansion Dept., Université Catholique de Louvain, 13 Ave G. Lemaître, B-1348 Louvain la-Neuve, Belgium).

4–6 July, **194th Meeting of the Society for Experimental Biology**, Belfast (Dr M. W. Steer, Dept of Botany, Queen's University, Belfast, UK).

11–13 July, **Polypeptides Hormones**, Baltimore (E. G. Bassett, Miles Laboratories Inc., PO Box 40, Elkhart, Indiana, 46515).

15–22 July, **Bioethics and Public Policy**, Boulder (A. Perry, Institute of Society, Ethics and the Life Sciences, 360 Broadway, Hastings-on-Hudson, New York 10706).

16–19 July, **Endocrinology '79**, London (Conference Secretariat, The Endocrine Unit, Royal Postgraduate Medical School, Du Cane Road, London, W1, UK).

17–20 July, **INTERMAG—Magnetism and Magnetic Materials**, New York (Dr E. F. Luborsky, General Electric R&D Center, PO Box 8, Schenectady 12301).

19–21 July, **Genetic Aspects of Fertility and Fetal Wastage**, Southampton (European Society of Human Genetics, Dr M. Seabright, Wessex Regional Cytogenetics Unit, Salisbury General Hospital, Salisbury, UK).

1–3 August, **Theoretical and Practical Aspects of Recombinant DNA Techniques**, Sao Paulo (Prof. F. J. S. Lara, Dept. of Biochemistry, Institute of Chemistry, University of Sao Paulo and Institute Butantan, Sao Paulo 20780, Brazil).

13–24 August, **The Scientific and Mathematical Foundations of Engineering Acoustics**, Massachusetts (R. H. Lyon, Massachusetts Institute of Technology, Room 3-366, Dept. of Mechanical Engineering, Cambridge, Massachusetts 02139).

15–17 August, **20th Canadian High Polymer Forum**, Quebec (Dr. I. H. McEwan, Canadian Industries Ltd, Paint Research Laboratory, 1330 Castlefiled Avenue, Toronto, Ontario, Canada M6B 4B3).

26–31 August, **Biochemical Development of Nervous Tissue in Culture**, Tel Aviv (Dr E. Giacobini, Dept. of Biobehavioral Sciences, University of Connecticut, Storrs, Connecticut).

27–31 August, **The Teaching of Chemistry—Interaction between Secondary and Tertiary Levels**, Dublin (Professor D. J. Waddington, University of York, UK).

28 August–1 September, **Neurochemistry of the Retina**, Athens (Dr N. G. Bazan, Instituto de Invetigaciones Bioquimicas, Univ. Nacional del Sur—Conicet, Av. Alem 1253, 800—Bahía Blanca, Argentina).

APPOINTMENTS VACANT

UNIVERSITY OF SURREY

DEPARTMENT OF BIOCHEMISTRY

LECTURER IN BIOCHEMISTRY

Applications are invited from suitably qualified graduates for a Lectureship in Biochemistry in the Biochemistry Department. Preference will be given to applicants with postgraduate experience and an interest in mammalian or physiological biochemistry. Industrial experience would also be advantageous.

Salary will be within the range £3,883 to £7,754 per annum according to qualifications and experience.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH, or Tel: Guildford 71281, Ext. 452. Application from men or women in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent to the above by March 12, 1979. 9761(A)

CHAIRPERSON, PROFESSOR OF CHEMISTRY

DEPARTMENT OF CHEMISTRY

State University of New York at Albany—Applications are invited for this position to start on September 1, 1979 or as soon thereafter as possible. The Department of Chemistry has a commitment to continuing development of outstanding programs in research and teaching and seeks a Chairperson to provide leadership in these areas and to guide the future growth of the department. The applicant should be a chemist of senior rank, with an established reputation in research and interest in teaching and administration. Each applicant should send a resume and the names of at least three references to: J. A. Zubieta, Chairman, Search Committee, Department of Chemistry, State University of New York at Albany, Albany, New York 12222. Applications should be completed before March 30, 1979. An EO/AA employer. 9743(A)

Graduate Biologist

In our group studying new approaches to drug therapy of enteric disease a vacancy exists for a pharmacologist or physiologist with a particular interest in gastrointestinal function.

We should be pleased to consider newly qualified graduates in the above disciplines (2:i Hons. degree minimum standard) through to PhDs with up to one year's post doctoral experience. Experience of *in vivo* experimentation is desirable and an interest in goal orientated research and drug evaluation essential.

Walton Oaks is pleasantly situated in the Surrey countryside near Dorking and Reigate. The Company provides excellent working conditions including flexible working hours.

Application forms (to be returned by March 16) may be obtained from **Mrs. M. R. Minchin, Personnel Officer, Beecham Pharmaceuticals Research Division, Animal Health Research Centre, Walton Oaks, Dorking Road, Tadworth, Surrey. (Telephone: Tadworth 4444).** 9785(A)

Beecham Pharmaceuticals

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of

SENIOR LECTURER

in the

DEPARTMENT OF VETERINARY PATHOLOGY

Candidates must be veterinarians with a Ph.D. in Pathology and teaching experience at University level. Salary scale: K£2,988 to K£3,984 per annum (K£1 equals £1.34 sterling). The British Government may supplement salary by £5,430 per annum (sterling) for married appointee or £3,648 per annum (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages; superannuation scheme; medical aid scheme; various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University of Nairobi, P.O. Box 30197, Nairobi, Kenya by April 5, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9720(A)

MEDICAL RESEARCH COUNCIL

LABORATORY ANIMALS CENTRE

TWO RESEARCH OFFICERS

One post is in the Centre's Accreditation Department. Its duties will include visiting commercial breeders of laboratory animals throughout Great Britain who are accredited or recognised by the Centre.

One post is in the Director's Department and is concerned with a research programme into Specific Pathogen Free cats, with some administrative responsibility for the day-to-day running of the department.

Candidates for either post should have at least two years' postgraduate experience in biology or zoology; a knowledge of small animals would be an advantage but not essential. Salary according to age, qualifications and experience plus £354 London Weighting. Contributory Superannuation Scheme.

Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to: The Director, M.R.C. Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

MRC
Medical Research Council
9621(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited from registered Medical, Dental or Scie
graduates for the post of

LECTURER

in the

DEPARTMENT OF ANATOMY

The appointment carries responsibil for teaching preclinical medical an or dental students at ordinary a honours levels. The appointee m engage in research work. Salary ran £3,883 to £7,754 per annum. Dut to commence not later than October 1979.

Applications (two copies), togetl with the names and addresses of thi referees, should be forwarded to t Vice-Principal (Administration) a Registrar, University College, P. Box 78, Cardiff CF1 1XL, from wh further details may be obtained. Cl ing date: March 31, 1979. Referer 1720. 9765(A)

UNIVERSITY OF NOTTINGHAM

SCHOOL OF AGRICULTURE

TEMPORARY LECTURESH in SOIL SCIENCE

There will be a vacancy for Lecturer in Soil Science in the Depa ment of Physiology and Environment Studies. The appointment will be f two years from September 1, 197 with a possible extension for the thi year, and it will be made in the fi three steps of the Lecturer Scale.

The main emphasis in the S Science Section relates to physical a clerical aspects of soil/plant relatic ships and it is expected that the p son appointed would strengthen the interests: research experience is des able.

Further particulars and forms application, returnable not later th March 12, 1979, from the St Appointments Officer, University Nottingham, University Park, N tingham NG7 2RD. Ref. No. 675. 9766(A)

UNIVERSITY OF ST. ANDREWS

DEPARTMENT OF ANATOMY AND EXPERIMENTAL PATHOLOGY

Applications are invited for the post of

TECHNICIAN (GRADE 4)

in the above Department. The successful applicant will take charge of the dissecting room and embalming suite, participate in the preparation of material for display in the departmental museum and assist with the preparation of teaching material.

Salary at appropriate point on scale £2,955 to £3,402 per annum (under review).

Applications, with the names of two referees should be sent to The Establishments Officer, The University, College Gate, St. Andrews, Fife, by March 2, 1979. 9792(A)

UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for the following posts in the

DEPARTMENT OF FOOD SCIENCE AND TECHNOLOGY

PROFESSOR/ASSOCIATE PROFESSOR IN FOOD SCIENCE

Applicants should have a good B.Sc. in Food Science and Ph.D. in any area of Food Science and Technology with wide teaching and research experience at University level. Past experience in setting up and organising new Food Science Laboratories would be of advantage. The appointee would be required to teach in his/her area of speciality in an integrated undergraduate training programme for B.Sc. (Food Science) and B.Sc. (Agric) courses. The appointee would also be required to initiate and supervise research projects in the area of Food Science both at undergraduate and postgraduate levels.

LECTURER/SENIOR LECTURER IN FOOD ENGINEERING AND FOOD MANUFACTURE

Applicants should have a good B.Sc. in Food Science and Ph.D. in Food Engineering or Food Manufacture with considerable teaching and research experience at University level. Past experience in setting up new Food Science Laboratories would be advantageous. The appointee would be required to teach all aspects of Food Engineering and Food Manufacture to undergraduate students studying for B.Sc. (Food Science) and B.Sc. (Agric). The appointee would also be expected to initiate and supervise research programmes in the area of Food Science both at graduate and postgraduate levels.

SENIOR LECTURER/LECTURER IN FOOD MICROBIOLOGY

Applicants should have a good B.Sc. in Food Science and a Ph.D. in Food Microbiology with considerable teaching and research experience at University level. Experience in setting up new Food Microbiology Laboratories would be advantageous. The appointee would be required to teach Food Microbiology to students studying for B.Sc. (Food Science) and B.Sc. (Agric). The appointee would also be required to initiate and supervise research work in the area of Food Microbiology at undergradute and postgraduate levels.

LECTURER IN FOOD ECONOMICS AND MANAGEMENT

Applicants should have a good B.Sc. in Food Science or Home Economics and Ph.D. in Food Economics and Management with considerable teaching and research experience at University level. The appointee will be required to teach Food Economics and Management to students studying for B.Sc. (Food Science) and B.Sc. (Agric). The appointee would also be required to initiate and supervise research work in Food Economics and Management both at graduate and postgraduate levels.

Salary Scales (Salaries are exclusive of 50% expatriation allowance): Professor £T2,700 p.a.; Associate Professor £T2,380 to £T2,580 p.a.; Senior Lecturer £T1,980 to £T2,480 p.a.; Lecturer £T1,620 to £T1,980 p.a. (£T1=£1.22 sterling.) The British Government may supplement salaries in range £4,356 to £5,964 p.a. (sterling) for married appointees and £2,754 to £4,038 p.a. (sterling) for single appointees (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family pasages; F.S.S.U.; biennial overseas leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania, by April 8, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9796(A)

UNIVERSITY OF CALIFORNIA, BERKELEY

DEPARTMENT OF
ENTOMOLOGICAL SCIENCES,
COLLEGE OF
NATURAL RESOURCES

FACULTY POSITION IN INSECT PATHOLOGY

Full-time, 11-month research (75 per cent) and teaching (25 per cent) position available in insect pathology at the Assistant Professor level available July 1, 1979. Expertise mandatory in one of the following areas: bacteriology, comparative virology, mycology, or protozoology. Ph.D. and background in pathology required and postdoctoral experience desirable.

Responsibilities will be in basic and applied research and teaching in insect pathology and pest management. Experience in pathogen-insect relationships, pathogenicity, and the manipulation of pathogens for insect control will be weighting factors when judging applicants.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of three references by April 1, 1979 to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an Equal Opportunity/Affirmative Action Employer. 9755(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited
for the post of

SENIOR LECTURER

in the
DEPARTMENT OF PHARMACY

Applicants must have a good degree in Pharmacy and a Ph.D. in Pharmaceutics. In addition the applicants are expected to have teaching and research experience at University level. Those with postgraduate qualifications in related branches of Pharmacy will also be considered. Salary Scale: K£2,988 to K£3,984 per annum (K£1 equals £1 sterling). The British Government may supplement salary by £5,430 per annum (sterling) for married appointee or £3,648 per annum (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages; superannuation scheme; medical aid scheme; various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University of Nairobi, P.O. Box 30197, Nairobi, Kenya by April 5, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9759(A)

Industrial Scientist

Senior Scientific Officer/Higher Scientific Officer

Applications are invited for the above pensionable post in the Industrial Science Division of the Department of Commerce situated at 17 Antrim Road, Lisburn, Co Antrim.

The successful candidate will work in a section which is involved in the continuous survey of international innovation and the technical appraisal of research and development projects.

The duties will involve the vetting of submitted projects and the evaluation of them in the context of existing technology or innovations to be found in patent and other literature.

The Industrial Science Division offers Industry and Government a wide range of scientific and technical services to aid in legislative administration, production, quality control and research and development.

The Division has substantial library facilities for the use of the successful candidate, and the services of the Information Officer may be called upon to survey the literature by means of computer links with UK and foreign data bases.

Appointment may be made at either Senior Scientific Officer or Higher Scientific Officer.

Applicants should normally have had some experience of Research and Development in either the pure or applied fields and preferably be qualified as chemists, chemical engineers, chemical technologists or physicists. Applicants must have industrial experience preferably in more than one manufacturing situation.

SENIOR SCIENTIFIC OFFICER

Over 25 and under 32 years of age on 31 December 1979 and possess a 1st or 2nd class honours degree in Chemistry, Physics, Chemical Engineering or Chemical Technology and have at least 4 years' appropriate post-graduate experience as outlined above.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age on 31 December 1979 and possess an Honours degree in Chemistry, Physics, Chemical Engineering or Chemical Technology and have at least 2 years' appropriate post-graduate experience as outlined above.

Exceptionally, applications may be considered from candidates over the age limit who have specialised experience.

The Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainments and experience) to be best qualified.

SALARY SCALES

Senior Scientific Officer—£5,154-£6,898
Higher Scientific Officer—£4,101-£5,448

The salary will be subject to review with effect from 1 April 1979.

Grading and Starting salary will be related to qualifications and experience.

Please write or telephone for an application form quoting job reference SB 77/79/NA to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext. 256). Completed forms must be returned to arrive not later than 8 March, 1979.

9707(A)

NORTHERN IRELAND CIVIL SERVICE

MEDICAL LAB TECHNICIAN

Graduate preferred, trained in light and transmission electron microscopy, required as soon as possible to work in Oxford. Knowledge of day-to-day maintenance of an up-to-date electron microscope an advantage. Manufacturers contract for regular major service and breakdowns maintained. Initial three year contract on current Whitely Council scales.

Apply for further details to: Director, L.E.P.R.A., Fairfax House, Colchester. 9704(A)

UNIVERSITY OF DAR ES SALAAM
TANZANIA

Applications are invited for the following posts in the

DEPARTMENT OF AGRICULTURAL ENGINEERING AND LAND PLANNING

LECTURER/SENIOR LECTURER/ASSOCIATE PROFESSOR IN SOIL AND WATER ENGINEERING

Candidates should possess B.Sc. in Agricultural Engineering, Engineering, Agriculture with engineering specialisation or Geography together with M.Sc. and/or Ph.D. with emphasis on Soil and Water Engineering; and/or Land Planning. Practical experience with responsibility in Land Planning and management for arable and livestock farming; soil conservation and/or irrigation is desirable, as is teaching experience. The appointee will be required to teach in the B.Sc. and M.Sc. programmes in the general area of Soil and Water Engineering with emphasis on Land evaluation, Land capability, classification and Land development for agricultural production including arable and livestock farming. He/she will be expected to supervise B.Sc. and M.Sc. work and undertake research in this area of study, and develop liaison with field staff in government and parastatal organisations.

LECTURER/SENIOR LECTURER/ASSOCIATE PROFESSOR IN PROCESSING AND STORAGE OF AGRICULTURAL CROPS

Candidates should possess a B.Sc. in Agricultural Engineering, Agriculture or Engineering preferably together with M.Sc. in a relevant specialist study. Responsible practical and/or research experience is also required and teaching experience would be an advantage. The appointee will be required to teach in B.Sc. and M.Sc. programmes in the general area of farm village and estate level processing of foodstuffs including crop drying and storage, processing of dairy products and crops of economic importance such as coffee, cotton, sisal, sugar. He/she will be required to supervise students undertaking special studies; participate in the Department's research programme; collaborate with and provide advice to units within and outside the University.

LECTURER/SENIOR LECTURER/ASSOCIATE PROFESSOR IN FARM AND RURAL STRUCTURE

Candidates should possess a B.Sc. in Agricultural Engineering, Agriculture or Engineering preferably with M.Sc. or Ph.D. in a relevant area of study. Responsible practical and/or research experience is also required and teaching experience is desirable. The appointee will be required to teach in B.Sc. and M.Sc. programmes in the general area of functional and constructional aspects of structures for livestock, storage and processing; layout of buildings and equipment and provision of service. Particular attention is given in the Department to requirements at farm and village level. It is anticipated that the expert will disseminate sound practice in the field through liaison with rural communities and advisory workers. He/she will be expected to undertake research and development work.

LECTURER/SENIOR LECTURER/ASSOCIATE PROFESSOR IN FARM POWER AND MECHANISATION

Candidates should be holders of B.Sc. in Agricultural Engineering or in Agriculture with strong mechanisation option and responsible experience in the application and management of farm machinery in agricultural producton. A relevant M.Sc. or Ph.D. is highly desirable, as is teaching experience. The appointee will be required to teach in the B.Sc. and M.Sc. programmes in the general area of farm power and machinery management, and to supervise students undertaking special duties. He/she will be expected to contribute to the Department's research programme and work in conjunction with other units within and outside the University when appropriate.

Salary scales (salaries exclusive of 50% expatriation allowance): Associate Professor £T2,380 to £T2,580 p.a.; Senior Lecturer £T1,980 to £T2,480 p.a.; Lecturer £T1,620 to £T1,980 p.a. (£T1=£1.22 sterling.) The British Government may supplement salaries in range £4,356 to £5,220 p.a. (sterling) for married appointees and £2,754 to £3,330 p.a. (sterling) for single appointees (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages; F.S.S.U.; biennial overseas leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania, by April 8, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9797(A)

CHARING CROSS HOSPITAL
SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

required for Tissue Typing Section of our Haematology Department. State Registration and experience in HLA Typing essential. For further details, please ring Mr T. Fletcher, Senior Chief Medical Laboratory Scientific Officer, Haematology, on (01)-748 2040, Bleep 91.

Application forms from District Personnel Department,
Charing Cross Hospital, Fulham Palace Road,
Hammersmith, London W6

9790(A)

UNIVERSITY OF DUBLIN
Trinity College

DEPARTMENT OF PHYSIOLOGY
LECTURER

Applications are invited from medical, dental or science graduates for this position which carries main responsibility for teaching in the following courses:

Histology (some general and all special) to Dental students.

Histology to Pharmacy Students.

Anatomy and Physiology: a co-ordinated course to students of Remedial Linguistics (Speech Therapy).

A research interest is essential in an area or areas related to the teaching programmes.

Salary scale: £4,232 to £8,321 per annum. Appointment is likely to be made within the range £4,232 to £4,680.

Application forms and further particulars relating to this post may be obtained from:

The Establishment Officer,
The Establishment Officer,
West Theatre,
Trinity College,
Dublin 2

to whom completed applications should be sent **not later than March 14, 1979.**

9706(A)

CHARING CROSS HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral Research Assistant interested in reproductive biology with specific reference to the placenta. The applicants will be expected to have experience in membrane biochemistry, immunology and cell biology. Salary on scale £3,883 to £6,555 plus £450 London Allowance. Further details obtainable from Dr Contractor, 01-748 3441, extension 127.

Applications including full curriculum vitae and names of two referees should be sent to The Secretary, Charing Cross Hospital Medical School, The Reynold's Building, St Dunstan's Road, London W6 8RP. (Ref: 470/1).

9771(A)

MEDICAL RESEARCH COUNCIL
DEVELOPMENTAL NEUROBIOLOGY UNIT
INSTITUTE OF NEUROLOGY

Applications are invited from young postdoctoral morphologists to participate in a programme to study effects of metabolic factors on brain development. Research experience in quantitative morphological methods, light and electron-microscopic autoradiographic, and immunohistochemical techniques will be of advantage. The appointment will be for one year in the first instance with the possibility of extension for a further two years. Salary will be at the appropriate point on the MRC scale for non-clinical scientific staff.

Applicants should send a Curriculum Vitae giving full details of qualifications and experience, and the names of two referees to: Dr R. Balazs, MRC Developmental Neurobiology Unit, Institute of Neurology, 33 John's Mews, London WC1N 2NS. 9734(A)

UNIVERSITY OF CALIFORNIA, BERKELEY
DEPARTMENT OF ENTOMOLOGICAL SCIENCES, COLLEGE OF NATURAL RESOURCES
FACULTY POSITION IN NATURAL PRODUCTS CHEMISTRY

Full-time, 11-month research (80 per cent) and teaching (20 per cent) position available in Natural Products Chemistry at the Assistant Professor level. Ph.D. in organic chemistry or other fields(s) relevant to natural products required with evidence of interest in chemicals active in insects.

Responsibilities will be in basic and applied research involving bioactive chemicals from insects, plants, and other biological materials that influence insect growth, development, reproduction, and behaviour. Research will include identification and synthesis of active components, and studies on their potential use in managing insect populations. Teaching duties may include developing a course in chemical ecology, environmental chemistry, insect biochemistry, or chemical pest control.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of at least three references by April 1, 1979 to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an Equal Opportunity/Affirmative Action Employer.

9756(A)

Biochemistry Technician required for research project involving glycoprotein separation and metabolism in calcified tissues. Experience with chromatographic, immunochemical and radioisotopic techniques useful, but not essential. Salary on Whitley Council Medical Laboratory Scientific Officer scale £3,261 to £4,680 per annum, according to age, qualifications and experience. Apply giving curriculum vitae and the names of two referees to: Dr J. T. Triffitt, M.R.C. Bone Research Laboratory, Nuffield Department of Orthopaedic Surgery, University of Oxford, Nuffield Orthopaedic Centre, Oxford OX3 7LD. 9772(A)

TWO NON-MEDICAL RESEARCH ASSISTANTS

required in the Host Defence Unit of the Department of Medicine, Cardiothoracic Institute, to assist in a three-year project investigating phagocyte function and muco-ciliary clearance mechanisms in human and animal respiratory infections. Practical experience in either humoral/cellular immunology, electron microscopy, or cell physiology/biochemistry essential.

Applications, stating age, qualifications and giving details of practical experience, with particular reference to the areas stated, together with the names and addresses of two referees to R. A. Perkins, Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP. Please quote reference HDU 1/79. 9773(A)

LABORATORY SCIENTIFIC OFFICER required in Department of Oral Immunology and Microbiology for three years, for research into immunity to Streptococci in man and animals. Experience in immunology and/or microbiology desirable. Salary for qualified Laboratory Scientific Officer not less than £3,261, on scale rising to £3,930, plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. I.M.I.

9794(A)

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE
AGRICULTURAL CHEMISTRY DIVISION

SPECIALIST ADVISER ANALYTICAL CHEMISTRY)

Applications are invited for a post of Specialist Adviser (Analytical Chemistry) in the Division's Analytical Services Unit. Applicants should have a degree or equivalent qualification in Chemistry or Agricultural Chemistry. Experience in the establishment operation and control of large scale analyical procedures woud be an advantage.

The salary will, according to age, qualifications and experience, be on one or other of the following scales:-

Grade IV—£2,998 (Honours — 1st or 2nd Class — £3,167) rising to £3,924

III—£4,178 riisng to £6,898

Further particulars and application forms may be obtained from the Secreary, the West of Scotland Agricultural College, Auchincruive, Ayr KA6 5HW with whom applications should be odged not later than March 2, 1979.

9744(A)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the post of **SRC** Postdoctoral Research Associate to work on the kinetics of the coupled transport of β-galactosides and protons into *Escherichia coli*. Applicants with experience of pre-steady-state kinetics are particularly wanted but experience in the fields of membrane transport or bioenergetics would also be considered relevant. Further details may be obtained from Dr I. C. West.

The apopintment will be for three years, starting as soon as possible. The starting will be at the appropriate point on the 1A Research Associate scale (£4,382 at age 26, under review).

Applications, including a *curriculum vitae* and the names of two referees, should be sent to the Administrative Assistant, Department of Biochemistry, The University of Newcastle upon Tyne, Newcastle upon Tyne, NE1 7RU.

9745(A)

THE ROYAL FREE HOSPITAL HAMPSTEAD

MEDICAL PHYSICS TECHNICIAN GRADE I

Salary Scale: £5,787 to £6,576 per annum (including all allowances)

To be in charge of large Inter-departmental Mechanical Workshops based in one of London's largest and most modern Hospital/Medical School complexes.

The Workshop is responsible for making scientific and research equipment required by a variety of Hospital and Medical School Departments.

The successful applicant will have had extensive closely related experience in a multi-user Department and have proven ability to supervise the work of junior staff.

Candidates must possess either a recognised formal qualification or a minimum of 9 years' experience in a relevant field.

Application form (to be returned by March 7, 1979) and Job Description available from the Personnel Departments, The Royal Free Hospital, Pond Street, Hampstead, London, NW3 2OG. Telephone: 794-0500 Ext. 4286. Please quote ref: 0762.

Camden and Islington Area Health Authority (T).

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Agricultural Entomologist - Tropical Agricultural Mission Bolivia

To work with Sugar Cane Growers Association's (CIMCA) research team on research station north of Santa Cruz. To carry out an integrated control programme on pests in sugar cane involving both insecticidal and biological control methods in addition to testing of resistant material. Will also be required to train local staff in sugar cane pest control methods.

Appointment 2 years, salary (UK taxable) in range £6,400 to £8,400 p.a., plus variable tax-free overseas allowance in range £1,440 to £2,825 p.a. (Ref. 331X)

Crop Physiologist Botswana

To work as part of a 3-man team including Tropical Agronomist and Soil Physicist for a Dryland Farming Research Scheme—Phase III, situated at the Agricultural Research Station, Gaborone, Botswana.

The crop physiologist will study the edaphic and aerial factors which are optimum for crop growth (mainly sorghum). This work will include the study of water and energy balances of the sorghum crop by analysing the climate in relation to crop growth, water use and also the soil physical properties. Specific studies are also necessary on the role of night temperatures on grain development and yield. The successful candidate will work to a Team Leader chosen from the Team. Applicants should have a degree in science or agricultural science with research experience in plant physiology and preferably overseas experience.

Appointment 3 years, salary (UK taxable) in range £5,700 to £9,700 p.a., plus tax free overseas allowance in range £1,360 to £3,375 p.a. (Ref. 331X).

These posts are wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:—

HELPING NATIONS HELP THEMSELVES

Plant Protection Division Jealott's Hill Research Station have the following vacancies in the Botany Section of the Biological Research Group:

Technical Officer

Plant Physiologist–Ref DS/Bot 1

A plant physiologist with PhD or equivalent qualification is required to assist in the discovery and evaluation of new herbicides. Experience of experimental work in controlled environment rooms and under glasshouse conditions is desirable. The person appointed will join a multidisciplinary project team and will be responsible for the work of two small experimental teams which include graduate level staff.

Experimental Officer

Plant Physiologist–Ref SRS/Bot 2

A graduate plant physiologist with 2/3 years' relevant experience is required to join a team carrying out experiments in controlled environment rooms and glasshouses on new herbicides The job holder will supervise a team of one or two assistants and will respond to the Technical Officer with overall responsibility for the work programme.

Experimental Officer

Field Trials–Ref SRS/Bot 3

A graduate with a degree in Botany or Agricultural Sciences and at least two years' practical experience of field experimentation is required to organise and perform the initial field screening of Plant Growth Regulators. The person appointed will respond to a Technical Officer with overall responsibility for the work programme.

Jealott's Hill Research Station is situated on a pleasant country estate between Bracknell and Maidenhead and subsidised coaches run to and from Jealott's Hill and these two towns We offer good salaries and fringe benefits include membership of the ICI Profit Sharing Scheme and Pension Fund. We have a good self service restaurant and recreation club on site.

If you are interested in any of these vacancies please write for an application form quoting reference number to:

THE CITY UNIVERSITY

CHEMICAL ENERGY RESEARCH UNIT

POSTDOCTORAL SCIENTISTS

for staff positions in the above Unit The objective of the Unit is to provide research and consultancy services on energy to industry and government departments Candidates should have research experience in one of the following areas Electrochemistry, Corrosion Science, Gas Phase Catalysis, Solid State Chemistry

Salary within the range £3,883 to £5,842 per annum plus £450 London Allowance and U S S benefits Applications, together with the names of two referees should be sent to Dr A C C Tseung, Director, Chemical Energy Research Unit, The City University, Northampton Square, London EC1V 0HB

9762(A)

Ministry of Agriculture Fisheries and Food

ROYAL BOTANIC GARDENS
WAKEHURST PLACE, ARDINGLY, SUSSEX

Forest Tree Seed Physiologist

required to investigate the physiology of loss of viability in stored seeds of tropical forest trees with a view to overcoming the present difficulties encountered in their collection, transportation and storage. The work will involve determining and quantifying the "orthodox" or "recalcitrant" nature of their storage physiology; this aspect will be carried out at Wakehurst Place. The development of the results into practical and proven techniques will necessitate considerable periods of individual field work in the latter part of the project. Close co-operation with the Commonwealth Forestry Institute in the selection of species for investigation is essential. The appointment will be for a period of 3 years.

QUALIFICATIONS: An honours degree in botany, biology or forestry with at least 2 years relevant post graduate experience.

AGE: Applicants should preferably be under 30 years of age on 31 December 1979.

SALARY: Will be at higher scientific officer level—£4,101 rising to £4,415 per annum.

Application forms (for return by 8 March 1979) can be obtained from Miss S. Stephens, Ministry of Agriculture, Fisheries and Food, Room 504, Victory House, 30-34 Kingsway, London WC2B 6TU (telephone: 01-405 4310 extn. 318 or 319). 9736(A)

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY
RESEARCH FELLOW

Applications are invited for a posiion to work with Dr R. S. Jones and rofessor D. V. W. Parke on an A.R.C. upported project concerned with an spect of environmental carcinogenesis. Applicants (male or female) should be raduates of either chemistry or biohemistry and possess a Ph.D./D.Phil.

The appointment is for a period of years and will commence as soon as ossible at a starting salary within the ange of £3,883 to £6,553 per annum Range 1A).

Applications, in the form of a curriulum vitae, including the names and ddresses of two referees, should be ent to the Assistant Secretary (Peronnel), University of Surrey, Guildord, Surrey, GU2 5XH, to be received y March 15, 1979.

Further information may be obtained rom Dr R. S. Jones, in the Departnent of Biochemistry. 9728(A)

UNIVERSITY OF SALFORD
DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY
POSTDOCTORAL RESEARCH FELLOW

Required for a project sponsored by Pfizer Central Research, entitled 'Studies on the Synthesis of novel beta—Lactam Antibiotics' under the supervision of Dr S. M. Roberts. The appointment is tenable for one year in the first instance, commencing October 1, 1979.

Commencing salary within the range:— £3,883 to £4,382 p.a. (under review) USS.

Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (tel: 061-736 5843 ext. 215) to whom completed applications should be returned by not later than March 31, 1979, quoting reference no. CH/254/N. 9776(A)

UNIVERSITY OF ESSEX
Department of Chemistry
TEMPORARY LECTURESHIP IN ORGANIC CHEMISTRY

Applications are invited for a one-year Lectureship commencing October 1, 1979 on salary scale £3,883 to £7,754 (under review).

Applications (two copies), including a curriculum vitae and the names and addresses of two academic referees, should reach the Registrar (AG/69/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, by March 31, 1979. 9717(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
RESEARCH TECHNICIAN

Applications are invited for the post of Research Technician within a small team investigating the physical biochemistry of connective tissue, under a programme grant which is supported by the M.R.C. Candidates should be in possession of City and Guilds, H.N.C. or equivalent in chemistry and should have had experience in quantitative analysis. Inclusive initial salary related to qualifications and experience will be £3,711 to £4,263 per annum.

Enquiries to Dr A. Maroudas, Tel: 01-247 5454, Ext. 421. Application forms from The Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, quoting reference RTBJU/2/79. 9727(A)

POSTDOCTORAL POSITION for work on the reticulo-stimulating effect of vaccines from anaerobic coryneforms C. *parvum* vaccines). Applicants should have major interest in biochemistry and cell fractionation procedures. Send curriculum vitae and names and addresses of three referees to Dr C. S. Cummins, Anaerobe Laboratory, Viginia Polytechnic Institute and State University, Blacksburg, Va. 24061. An Equal Opportunity/Affirmative Action Employer.

9737(A)

Ministry of Agriculture, Fisheries and Food
Food Science Division, London

Chemist/ Biochemist

This post is in the Food Surveillance Section, which assists the Division in providing an advisory service on all aspects of food science, food technology and human nutrition, both at home and abroad.

The chemist/biochemist appointed will act as scientific secretary to the Steering Group on Food Surveillance and working parties on the Monitoring of Foodstuffs for Heavy Metals. The work will involve administering food surveillance programmes designed to determine the incidence of contaminants in food, identifying areas of future observation, preparing reviews and committee papers and presenting data in official reports.

Candidates, normally aged under 32, should have a good honours degree in chemistry, biochemistry or closely related discipline. At least 4 years' post-graduate experience, preferably including knowledge of mycology, analytical chemistry, food technology and toxicology, is essential. The ability to prepare technical papers and reports advantageous.

Appointment as Senior Scientific Officer (£5620–£7360) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 23 March 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/36/AE.*

Department of Agriculture and Fisheries for Scotland, East Craigs, Edinburgh

Agricultural Botanist

. . . to join a small team testing new varieties of fodder crop species to establish their distinctness, uniformity and stability. The agriculturalist appointed will assess the field performance of new species under Scottish conditions and undertake statutory certification of seed stocks.

Candidates, normally aged under 30, should have a good honours degree or equivalent in an appropriate discipline. At least 2 years' relevant post-graduate experience is essential. An interest in modern taxonomic methods and experience of herbage variety testing is highly desirable.

Appointment as Higher Scientific Officer (£4100–£5450) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 23 March 1979) write to Scottish Office, Personnel Division, PM(PTS)3, Room 404, 16 Waterloo Place, Edinburgh, or telephone Edinburgh 031-557 8400 ext 4311/5088. *Please quote ref: SA/18/DLA.*

PHYSICAL OCEANOGRAPHER
(109-025-026)

Salary: $16,500 – $34,045
Ref. No: 78-NCRSO-32-143 (N)
Fisheries and the Environment
Ocean and Aquatic Sciences
Bedford Institute of Oceanography
Dartmouth, Nova Scotia

The successful candidate will plan and conduct research on the physical processes which determine biological productivity on continental shelves, with a special emphasis on the role of tidal dynamics. The duties will involve participation in work at sea and extensive use of numerical simulation and analysis techniques.

Qualifications

Applicants must possess a Ph.D., or a lesser degree with evidence of research experience and productivity to a doctorate, in physical oceanography, physics, applied mathematics or a related field. Research experience and a demonstrated capacity to make original contributions in the study of continental shelf oceanography, particularly in the area of tidally-included shallow-water frontal systems, is required. Knowledge of English is essential.

How to Apply

Send your application form and/or résumé to:

FLINDERS MEDICAL CENTRE
Adelaide, South Australia
HOSPITAL SCIENTIST OIC ROUTINE MICROBIOLOGY

Flinders Medical Centre is an integrated university medical school and teaching hospital of 500 beds. The DEPARTMENT OF CLINICAL MICROBIOLOGY with a staff of 25 and headed by Assoc. Prof. P. J. McDonald is responsible for diagnostic services as well as clinical microbiology teaching and research with the School of Medicine, Flinders University.

The Department is presently divided into several sections including serology, virology, chlamydia, anerobic and cellular research and routine microbiology. Applications are invited for the position of OFFICER-IN-CHARGE — ROUTINE MICROBIOLOGY. This section, the largest in the Department, handles the routine diagnostic areas of bacteriology (including anaerobes and T.B.), parasitology and mycology. Approximately 3000 specimens are processed monthly.

The successful appicant will have had several years' experience in medical microbiology including diagnostic, teaching and developmental research responsibilities and by keeping abreast of current literature will be innovative in approach to diagnostic methods. The position itself carries responsibilities in the area of routine methods, evaluative projects and in-service training of staff as well as participation in the teaching of medical students and the departments research programs.

Salary is within the range $A10,891 to $A17,331 and it is expected the appointment will be made at the upper end of the range. After an initial period, personal reclassification to a higher scale is possible. A proportion of removal expenses will be provided.

Applications stating full curriculum vitae and confidential letters of recommendation pertaining to the position from two referees should reach The Administrator, Flinders Medical Centre, Bedford Park, South Australia, **5042** no later than March 27.

Further enquiries should be directed to the Senior Microbiologist, Mr T. R. Grimmond. Telephone 03-2759911. 9750(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
POSTDOCTORAL RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for a postdoctoral biochemist to work in collaboration with Dr Anne Grant and Professor J. Hermon-Taylor on the biochemistry and surface components of human pancreatic and other cancer cells in tissue culture. The post, supported by the Cancer Research Campaign, is available immediately and runs until December 31, 1981 with the possibility of extension. Salary in the range £5,551 to £6,612 (under review). Further particulars and applications forms available from Professor J. Hermon-Taylor (01-672-1255 Ext. 4716) Department of Surgery, or the Establishment Officer, St George's Hospital Medical Schoil, Cranmer Terrace, London SW17 0RE. 9724(A)

MEDICAL RESEARCH COUNCIL LABORATORY OF MOLECULAR BIOLO

Applications are invited for a requiring research on the structure chromatin. The person appointed be expected to pursue biochem studies as a member of a resea group working on the biochemistry three dimensional structure of nuc somes and higher order structu Experience in protein and nucleic a chemistry would be an advantage.

The appointment will be for th years in the first instance, start October 1, 1979. Candidates must h at least an upper second class hono degree and three years relevant p graduate experience.

Salary on scale starting from £4, per annum.

Applications, with full curricul vitae and names of two referees, sho be sent to the Administrative Sec tary, M.R.C. Laboratory of Molecu Biology, The Medical School, H Road, Cambridge CB2 2QH, to received not later than March 1979. 9806(A

THE UNIVERSITY OF MA CHESTER. There is a vacancy fo TECHNICIAN (Grade 5, Univer Scale) in the biochemical resea laboratories of the clinical dep ments at the Medical School (Stopf Building). Applicants should have least eight years experience in clinical chemistry or biochemical oratory and possess A.I.M.L.S. H.N.C. in appropriate subjects.

Salary scale (under review) £3, to £3,720 per annum.

Applications, quoting two refer should be sent as soon as possible Professor P. H. Adams, Department Medicine, Royal Infirmary, M chester M13 9WL from whom furt particulars may be obtained.
9760(A

UNIVERSITY OF GLASGO
SECOND CHAIR OF ZOOLOGY

The University invites applicati for a second chair in its Departm of Zoology.

Further particulars may be obtai from the Secretary of the Univers Court (Room 18), University Glasgow, Glasgow G12 8QQ, w whom applications (15 copies; copy in the case of overseas ap cants), giving the names and addres of three referees, should be lodged or before March 16, 1979.

In reply please quote Ref. 4270. 9710(A

MEDICAL RESEARCH COUNCIL
Radiobiology Unit, Harwell
MAMMALIAN GENETICIST OR CYTOGENETICIST

A scientist is needed to join a group studying the genetic effects of radiation and other mutagenic agents in mammals. The emphasis is on methods of exploring the sensitivity to mutagenesis of germ cells of different sexes, developmental stages and species in the intact animal Formal genetics and cytogenetics relevant to the mutagenesis work are also included Candidates with experience of genetics of higher organisms, or of handling rodent chromosomes, at either meiotic or mitotic stages, would be at an advantage.

Possible subjects of research include

(i) comparison of the sensitivity to mutagens of various mammalian species, with particular emphasis on methods of studying chromosome changes in oocytes and early embryos,

(ii) studies of the causes of chromosomal non-disjunction in mammals,

(iii) factors affecting the sensitivity of oocytes to mutagenesis.

There are excellent research facilities. The Unit also includes groups studying cell mutation, cytogenetics, pathology, and effects of radionuclides.

Applicants should hold a relevant good honours degree, with three year's research experience, and preferably a Ph.D. Salary and conditions of service according to M.R.C non-clinical scientific scales. Hostel accommodation for single, or housing for married, people may be available.

Applications, with curriculum vitae and names of two referees, should be sent to Administrator, M.R.C Radiobiology Unit, Harwell, Didcot, Oxon. OX11 0RD, from whom further particulars may be obtained. 9733(A)

UNIVERSITY OF BATH
BIOCHEMISTRY GROUP
RESEARCH OFFICER

required to work with Dr D. Hough on a S.R.C.-supported project to investigate 'The attachment of immunoglobulin to the membrane of human lymphocytes'. The work will include maintenance of lymphoid cell cultures, radiolabelling and radioimmunoassay of membrane immunoglobulins. Persons expecting to graduate in July may be considered for this post, which is available for two years

Commencing salary £3,384 per annum (under review).

Application forms from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 79/20/N. Closing date will be March 6, 1979 9708(A)

UNIVERSITY OF STIRLING
DEPARTMENT OF BIOCHEMISTRY
CHIEF TECHNICIAN

Applications are invited for the post of Chief Technician in Biochemistry The successful candidate will supervise the technical staff in the department and will be in charge of the teaching laboratories. Candidates should hold an HNC or equivalent qualification and should have experience in biochemistry or related area The post is tenable from April 1979 The salary will be within the Grade 6 scale £3,654 to £4,365 (under review)

Further particulars may be obtained from The University Secretary, University of Stirling, Stirling FK9 4LA

Closing date for applications March 7 9713(A)

Wellcome

Pathologist–Toxicologist

to join the Pathology Department of The Wellcome Research Laboratories located in Beckenham, Kent.

The Department is responsible for safety evaluation of new drugs and biologicals, including vaccines, for assessment and development of toxicological test methods, and it collaborates with other research workers at Beckenham and elsewhere within the Group The staff of the Department numbers about 70 people, including 12 graduates, and it has extensive facilities, including ample resources for many different types of research.

The successful applicant will report to the Head of the Department ,and take part in the routine work and research of the Department. Much of the work is based on morbid anatomy and experience of human or veterinary pathology is necessary. Knowledge of laboratory animal pathology would be advantageous, but it is not essential as further training could be given. Proven interest in research would be of value.

Applicants should have a medical or veterinary qualification and preferably a higher degree or qualification of the Royal College of Pathologists.

The Laboratories are situated in pleasant parkland surroundings within easy reach of Central London and conditions of employment are excellent and include subsidised canteen, pension scheme, 4 weeks' holiday, relocation expenses where appropriate and sports and social facilities.

Required for Electron Microscope Unit of the Anatomy Department to work under the direction of Grade 5 Technician The unit has an AEI EM 6B and a new JEOL CX100 with scanning facility and carries out work for other departments of the college Applicants should possess an O.N.C or equivalent qualification and have had three years' laboratory experience Salary on scale £3,153 per annum rising to £3,525 per annum inclusive (under review). Four weeks annual holiday Contributory pension scheme Apply in writing with full details to The Head Clerk (Ref 210230/N), King's College London, Strand WC2R 2LS. 9725(A)

UNIVERSITY OF LONDON
KING'S COLLEGE
RESEARCH TECHNICIAN GRADE 5

Required in Department of Physics, to work with Solid State Physics Group. Main responsibilities will be the maintenance, development and setting up of research equipment and preparation of samples Preference will be given to applicants with experience in either electronics or high vacuum and cryogenic techniques

Salary on scale £3,651 per annum inclusive (under review) rising to £4,185 per annum Four weeks annual holiday. Contributory pension scheme. Apply in writing with full details to: The Head Clerk (Ref 210232/N), King's College London, Strand WC2R 2LS 9726(A)

THE GERMAN CANCER RESEARCH CENTRE
in Heidelberg (Federal Republic of Germany)

invites applications for the post of

HEAD OF THE DIVISION
(Abteilungsleiter)

MOLECULAR BIOLOGY OF THE CELL

The applicant should have experience in research on structures of the nuclear genome and/or the regulation of gene activity at the molecular level.

Preference will be given to candidates with experience in methods of isolation and cloning of genes and gene fragments.

The applicant should be prepared to cooperate closely with other divisions in the German Cancer Research Centre; modern laboratory facilities and access to central services are provided.

Applications, together with a list of publications, should be sent by April 30, 1979 to:

Deutsches Krebsforschungszentrum,
Stiftungsvorstand, Im Neuenheimer Feld 280,
6900 Heidelberg 1, Federal Republic of Germany.
9742(A)

Veterinary Research

The Ministry of Agriculture, Fisheries and Food needs Research Officers in its veterinary laboratories at Weybridge and Shinfield. The main work of these laboratories is research into animal diseases and the means of dealing with them: examinations in connection with scheduled diseases and official control schemes are also carried out and certain biological products are prepared. Newly appointed Research Officers normally spend part of their first two years in training. During their careers they will broaden their experience by working on a variety of research subjects.

Central Veterinary Laboratory, Weybridge

In the Departments of Biological Products and Standards, Biochemistry, Diseases of Breeding, Bacteriology, and Virology.

Cattle Breeding Centre, Shinfield

For research into cattle and pig fertility and problems of breeding.

Candidates should normally be members of the Royal College of Veterinary Surgeons or expect to qualify in 1979, but candidates with an honours degree in an appropriate science subject may be considered, providing they have had at least 2 years' postgraduate practical experience in work relevant to veterinary science.

Appointment will be as Research Officer (Veterinary Service) with salary starting between £5,720 and £7,020, according to qualifications and experience, and rising to £8,240; Shinfield figures £275 less. There are prospects of promotion to posts carrying salaries of £9,500 and above. Non-contributory pension scheme.

For further details and an application form (to be returned by March 23, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote S/5077/4. 9714(A)

UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for the following posts in the

DEPARTMENT OF ZOOLOGY

LECTURER/SENIOR LECTURER IN MARINE BIOLOGY (Fish Taxonomy/Aquaculture)

Applicants should hold a Ph D. with several years research and teaching experience in Fish Taxonomy and/or aquaculture Appointee will be required to organise undergraduate courses in Fish Taxonomy and/or aquaculture and to teach and supervise research in his/her subject area at postgraduate level, to organise and carry out research in fish taxonomy and biology. He/she will have to work in collaboration with other members of the Department in an integrated research programme

LECTURER/SENIOR LECTURER IN MARINE BIOLOGY (Marine Ecologist)

Applicants should have a Ph D. with several years research and teaching experience in Benthic Ecology/Coral reef ecology of tropical waters. The appointee will be required to organise undergraduate courses in Marine Ecology and to teach in his/her area of specialisation at postgraduate level; to plan and carry out research in Benthic Ecology/Coral reef ecology He/she will have to work with other members of the Department in an integrated research programme.

LECTURER/SENIOR LECTURER IN MARINE BIOLOGY (Fisheries Biology/Population Dynamics)

Applicants should hold a Ph.D. with research and teaching experience in Fisheries biology especially in the area of fish population dynamics The appointee will be required to organise undergraduate courses in Fisheries biology and to teach and supervise research in his/her subject area at postgraduate level, to organise and carry out research in Fisheries biology relevant to Tanzania He/she will be expected to work in collaboration with other members of the Department in an integrated research programme.

Salary Scales (Salaries are exclusive of 50% expatriation allowance). Senior Lecturer £T1,980 to £T2,480 p a, Lecturer £T1,620 to £T1,980 p a (£T1=£1 22 sterling.) The British Government may supplement salaries in range £4,356 to £4,782 p a (sterling) for married appointees and £2,754 to £3,018 p a (sterling) for single appointees (reviewed annually and normally free of tax) and provide children's education allowances and

Detailed applications (2 copies) with curriculum vitae and naming holiday visit passages. Family passages, F S S.U., biennial overseas leave. 3 referees to be sent direct to Chief Academic Officer, University of Dar es Salaam, P O. Box 35091, Dar es Salaam, Tanzania, by April 8, 1979.

Applicants resident in the U K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address 9798(A)

UNIVERSITY OF AUCKLAND
New Zealand

Applications are invited for the following full-time teaching position Conditions of Appointment and Method of Application are available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. Applications in accordance with 'Method of Application' will be accepted at any time up to March 31, 1979.

Commencing salary in accordance with qualifications and experience will be established within the range for Lecturers or Senior Lecturers, at present NZ$11,529 to NZ$16,780 per annum.

ANALYST IN GEOCHEMISTRY
Lecturer status:

The position would suit a graduate with a research degree in Geochemistry or in suitable aspects of Mineralogy and Petrology, and with training and experience in both X-ray flourescence and wet chemical techniques. Applicants should note that analytical equipment in the Geology Department includes XRF, AA, DTA, TGA, IR, XRD, X-ray cameras, microprobe, PDP8 computer, and HP10 calculator and XY plotter, with access to campus facilities for SEM and B6300 and Prime computer systems.

Duties are concerned with the departmental research programme and instruction of senior students in analytical techniques and related topics. The major component of this work will be bulk rock and trace element analyses of selected samples, and some water analyses. The Analyst will be able to function as a co-worker in some of these research topics. In addition, it is expected that the Analyst will develop a personal research programme in Geochemistry as a second priority. 9781(A)

UNIVERSITY OF EDINBURGH
THE EDINBURGH SCHOOL OF AGRICULTURE
UNIVERSITY DEMONSTRATOR IN ANIMAL PRODUCTION

Applications are invited from suitably qualified graduates for the post of UNIVERSITY DEMONSTRATOR IN ANIMAL PRODUCTION This is a new post and is tenable for a period of up to three years.

The successful candidate will be involved in demonstrations and practical classes with farm animals for postgraduate, graduate and H.N.D. students. There will be involvement with lecturing and an opportunity to develop research interests.

Salary scale· £3,384 to £4,882 per annum.

Further details are available from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL to whom applications should be sent not later than March 15, 1979. Please quote Reference 1022. 9769(A)

---

e and postdoctoral positions are availle for studies on the protein synthesing system with special emphasis on ructure and function of mRNP rticles, ribosomes—topography, biomesis and function—under various nditions of growth and development Teaching opportunities available, oply with resumé to Professor ruce H. Sells, Laboratories of olecular Biology, Faculty of Medine, Memorial University of Newundland.

9751(A)

Wellcome

Senior Technician

BIOCHEMICAL RESEARCH FROM £3,400

to join the Biochemical Research Department of The Wellcome Research Laboratories, located at our main manufacturing site in Dartford, Kent.

The successful candidate will assist a scientist in endocrinological research, in particular on the mechanisms of polypeptide hormone secretion

Candidates should be qualified to H.N.C. level in biology/chemistry or equivalent and have approximately two years' relevant experience. There will be an opportunity for the successful candidate to progress by day-release to a B.Sc. degree

The Wellcome Foundation Limited is a major British-owned international pharmaceutical organisation producing a wide range of chemical and pharmaceutical products

Excellent benefits include 4 weeks' holiday, pension, life assurance and sick pay schemes, subsidised restaurant, first class sports and social facilities and generous assistance with relocation expenses, where appropriate.

For further details and an application form, please write to or ring
Ian Griffiths, Personnel Division,
The Wellcome Foundation Limited,
Dartford, Kent.
Tel: Dartford (32) 23488, ext. 2061.

9731(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of

LECTURER IN BIOCHEMISTRY

tenable from October 1979.

The successful candidate will be expected to be interested in mammalian and medical biochemistry and to participate in teaching and research in these areas A medical degree would be an advantage although is not essential The Department provides courses for science, medical and dental undergraduates Excellent facilities are available for most types of biochemical research

Salary within the range £3,883 to £7,754 p a (plus USS), depending on age, qualifications and experience

Applications (2 copies) naming 3 referees should be sent by March 30, 1979 to Miss L R Heyes, Senate Registry, University of Birmingham, P O. Box 363, Birmingham B15 2TT, from whom further particulars may be obtained

9779(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF OCEANOGRAPHY

Applications are invited for the post of Lecturer in the Department of Oceanography. The post is tenable immediately

The person appointed will be expected to teach and carry out research in Marine Chemistry

The initial salary will be within the range £3,883 to £5,367 per annum on a scale rising to £7,754 per annum.

Applications, together with the names of three referees, should be received not later than March 22, 1979 by The Registrar, The University, P.O Box 147, Liverpool L69 3BX, from whom further particulars may be obtained Quote Ref RV/498/N

9777(A)

Director

National Center For Toxicological Research Food and Drug Administration

The U.S Food and Drug Administration is seeking candidates for the position of Director of the National Center for Toxicological Research (NCTR) The Center, an interagency facility, conducts research programs on the biological effects of potentially toxic chemical substances found in the human environment The Director of NCTR provides leadership and direction to all Center operations and provides scientific liaison between NCTR and other Government agencies, private organisations and the worldwide academic, scientific and medical communities The Center is located in Jefferson, Arkansas and has a staff of approximately 600 employees The Center is well-equipped with sophisticated and modern laboratories to support advanced research in virtually all areas of toxicology

FDA is looking for candidates of recognised scientific distinction and administrative ability Candidates should possess an advanced degree in a relevant field of science (such as a Ph D in biochemistry, pharmacology, toxicology, or statistics, an M D., or a D V M.) The position also requires appropriate research experience and an association with multidisciplinary issues This is a Civil Service position that pays up to $47,500 per year in basic salary. The Director will also be eligible to receive performance bonuses and special stipends that may result in a higher total pay This position has been designated for inclusion in the Federal Government's Senior Executive Service (SES), and the selectee will be required to enter the SES. Information on the SES will be available for interested applicants

Send curriculum vitae and/or Standard Form 171 (Personal Qualifications Statement) and bibliography to

HEW/Food and Drug Administration,
NCTR Search Committee,
c/o Ms. Patricia Sykes,
Rm. 9-89, 5600 Fishers Lane,
Rockville, Maryland 20857, U.S.A.

FDA/An Equal Opportunity Employer.

Microbial Physiologist

Overseas Assignment

The Kuwait Institute for Scientific Research, a rapidly expanding institute for applied science and technology, is seeking a Microbial Physiologist who is interested in the opportunity for a career challenge

In this position, you will be responsible for the yield coefficient and productivity studies of SCP production from LPG and methanol in bench-scale fermenters.

We require a PhD in Microbiology or Biochemistry with at least 3 years' experience in continuous culture techniques, microbial growth efficiency or hydrocarbon microbiology.

Kuwait Institute offers attractive salaries commensurate with qualifications and experience, furnished housing, liberal fringe benefits including round trip air tickets and free medical benefits.

Please airmail complete resume by April 1, 1979 to: **Mr. Habib Al-Sahhaf, Personnel Manager, Kuwait Institute for Scientific Research, P.O. Box 24885, Safat, Kuwait, State of Kuwait.** 9703(A)

Kuwait Institute for Scientific Research

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Land Resources Management, Perth, WA

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees —2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

Field: Coastal Dynamics

General The Division has 60 professional staff doing problem-oriented research on the environmental, societal, economic and technological implications of land use One program includes studies of the dynamics of both ocean and land in the coastal zone

Duties. The appointee will work in a multidisciplinary team and will be expected to develop a research program on the prediction of sea level oscillations on the coastline and the energetics of the coastline Other areas of interest are sediment motion and shore erosion, and transport of sand by wind

Qualifications: A PhD or equivalent research experience in applied mathematics, engineering, physical oceanography or physics The ability to relate scientific analysis to problems of resource management is essential.

Salary: Research Scientist or Senior Research Scientist $A15,422 to $A22,405 p a An outstanding applicant may be offered appointment at a higher level

Tenure: A fixed term of three years

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 284/91 should reach

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 21st March 1979

Applications in U S A and Canada should be sent to. The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W , Washington, D.C , 20036, U S.A 9775(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF GENETICS

Applications are invited for the temporary post of

POSTDOCTORAL RESEARCH FELLOW

in the above Department The successful candidate will participate in current research programmes involving the cloning of fungal and bacterial DNA and will be using techniques that include nucleic acid hybridisation, heteroduplex mapping and separation and mapping of restriction fragments Familiarity with some or all of these would be an advantage, but persons with related biochemical experience are encouraged to apply. Candidates should possess a Ph D degree The appointment will be made for a fixed term of three years with effect from October 1, 1979

Salary at an appropriate point on the IA Scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience

Informal enquiries about the post may be addressed in the first instance to Dr S Baumberg (ext 597) or Dr J C Wootton (ext. 7155) at the University (tel (0532) 31751).

Application forms and further particulars of the post may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 50/4/D

Closing date for applications March 31, 1979 9787(A)

UNIVERSITY OF ESSEX

CHAIR IN BIOLOGY

Applications are invited for a chair in Biology for appointment from October 1, 1979. The Chair will be filled in the fields of Developmental/Cell Biology, or microbial/molecular genetics

Applications (12 copies), including a curriculum vitae and the names and addresses of three referees, should reach the Registrar (C/1), University of Essex, Wivenhoe Park, Colchester CC4 3SQ, from whom further particulars may be obtained, by March 15, 1979 9716(A)

BIOCHEMICAL SOCIETY

Applications are invited for a senior post in the Society's Editorial Office The post involves responsibility for editorial processing of material for the **Biochemical Journal** and other Biochemical Society publications, and the successful applicant will be required to act as a deputy for the Editorial Manager As well as a degree in biochemistry or related subject it is essential that candidates (probably of age 35-45) should have had sound postgraduate experience of scientific editorial work and academic publishing and be capable of supervising the work of others, A salary commensurate with the seniority of this post will be offered Please apply in writing, giving the names of two referees, to the Eexcutive Secretary, Biochemical Society, 7 Warwick Court, London WC1R 5DP

9622(A)

FRIEDRICH MIESCHER-INSTITUT

seeks

EXPERIENCED PLANT CELL BIOLOGIST

to form and lead a group doing basic research on morphogenesis from single cells of corn and other cereals.

Applications, before April 1, 1979, to Dr R. R. Bürk, Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland 9735(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitab qualified persons for appointment the following positions

THE JOHN CURTIN SCHOOL O MEDICAL RESEARCH.

PROFESSORIAL FELLOW IN NEUROCHEMISTRY

DEPARTMENT OF PHARMACOLOGY

Applications are invited from neur chemists with recognised experien and expertise in the chemistry central synaptic transmission in t mammal for appointment as Pr fessorial Fellow in Neurochemistr The successful applicant will expected to lead a small neur chemical group within the Departme of Pharmacology and to take advanta of collaboration with other membe of the Department engaged on *in vi* investigations of central synapt mechanisms, particularly those invol ing amino acid and peptide tra mitters Further details may obtained from Professor D R Cur Head of Department

Closing date **April 13, 1979.**

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH FELLOWS

DEPARTMENT OF BEHAVIOURAL BIOLOGY

Two positions are available. App cants should have a higher degree a postdoctoral experience in expe mental psychology or animal behavio Work in the Department is mult disciplinary and has concentrated the development of the visual syste particularly in bird brains, and on t mechanisms of memory storage. F further details please contact Profes Richard Mark, Head of Departme

Closing date: **April 15, 1979.**

POSTDOCTORAL FELLOW

MOLECULAR BIOLOGY UNIT

The Unit (Head, Dr H Naora) exploring the molecular mechanis of post-transcriptional control animal cells This includes t problems of the HnRNA-mRNA p cursor-product relationship, the nucle processing of mPNA-precurs molecul using nucleic acid sequencing a DNA cloning Applicants should ha experience in this particular field research

Closing date **April 15, 1979.**

Salaries Professorial Fellow, $A30,7 p a , Research Fellow, in accorda with qualifications and experien within the range $A15,786 to $A20,6 p a , Postdoctoral Fellow, a fixed po within the range $A15,786 to $A20, p a Current exchange rates $A £0 56 sterling

Term of Appointment: Professor Fellow to retiring age (65 years), search Fellow for three years in first instance with the possibility extension to five years, Postdocto Fellow for two years

Other Conditions: Reasonable appoi ment expenses are paid Superannuat benefits are available for applica who are eligible to contribute Ass ance with housing is provided for appointee from outside Canberra

The University reserves the right to make an appointment or to ma an appointment by invitation at time

Prospective applicants should obt the further particulars from Association of Commonwealth U versities (Appts), 36 Gordon Squ London WC1H 0PF 9799(A

RESEARCH GROUP requires labo tory scientific officer to assist genetic and cell biology work invo ing tissue culture. Candidates w relevant experience preferred. Ap cations should be sent to the Admi strative Assistant, Paediatric Resea Unit, The Prince Philip Resea Laboratories, Guy's Hospital Med School, London Bridge SE1 9RT 9709(A

THE MAX-PLANCK-INSTITUTE OF BIOCHEMISTRY
8033 Martinsried/Munich

offers a postdoctoral position for a biochemist, preferentially with cell biological experience in the field of membrane proteins. Payment as research assistant (ca DM3,000, monthly).

Applications to Prof. E. Neumann, Max-Planck-Institut fur Biochemie, D-8033 Martinsried bei Munchen, Germany. 9748(A)

FELLOWSHIPS

Research Fellowships

St. Catherine's College and St. Hilda's College, Oxford University

The Rutherford Laboratory of the Science Research Council, St. Catherine's College and St. Hilda's College invite applications for two joint Research Fellowships, one at St. Catherine's College and one at St. Hilda's College. The aim of these "Atlas Fellowships" is to encourage theoretical studies – particularly with reference to those involving computers – in an area of research supported by the Rutherford Laboratory. These include the following broad fields: study of condensed matter by scattering of neutron beams; study of dense plasmas by the use of intense laser beams; use of electron beam lithography in fabrication of semi-conductor devices. The successful candidates will be expected to undertake independent research work and to have ideas on the programme they wish to follow.

The Fellows will have the rights and privileges of a Research Fellow to the relevant College. The possibility may exist for the Fellow to undertake some teaching. They will be expected to spend about half their time at the Rutherford Laboratory and will be provided access to exceptionally powerful computing facilities. The Rutherford Laboratory's involvement with numerous University research groups gives an opportunity for contacts with other research workers engaged on a wide range of exciting research programmes.

The Fellowship will be tenable for a period of up to three years and may be extended up to a period not exceeding five years. The stipend will depend upon the age and experience of the candidates selected within the broad range £4,500 to £7,500. (The stipends are currently under review). The Fellowship will carry the superannuation provisions under the SRC Principal Superannuation Scheme which is a non-contributory scheme. Candidates will normally be expected to take up the posts in October 1979.

For details of Research Fellows' rights at the two Colleges and application forms, write to the Personnel Group of the Rutherford Laboratory, Chilton, Didcot, Oxon OX11 0QX quoting reference No. VN 730.

The closing date for applications is 16th March, 1979.

RUTHERFORD
Science Research Council
Rutherford Laboratory, Chilton, Didcot, Oxfordshire OX11 0QX. Tel Abingdon 21900

9780(E)

DEPARTMENT OF EDUCATION, DUBLIN
POSTDOCTORAL RESEARCH FELLOWSHIPS
1979–80

Applications are invited for Research Fellowships in Science (excluding Medical and Social Science) and Engineering tenable in any one of the following Institutions in Ireland University College, Dublin, University College, Cork, University College, Galway, Trinity College, Dublin, An Foras Talúntais (The Agricultural Institute), Dublin 4, The Institute for Industrial Research and Standards, Dublin 9 Fellowships will be tenable for a period of two years with the possibility of an extension for a third year

Applicants should hold the degree of Ph D or have equivalent research experience Applications will be considered from engineers or technologists with suitable industrial experience Candidates should not be more than 30 years of age but, preferably, they should be under 28 years of age

Appointments will be effective from a date not earlier than October 1, 1979 The initial salary, which will depend upon qualifications and experience, will normally be within the range £3,775 to £4,277 per anum, but awards of up to £4,986 may be made in the case of engineers and technologists whose industrial experience or other special circumstances warrant it

Full particulars of the scheme including application forms may be obtained from the Secretary, Department of Education (Headquarters Section 3), Marlboro' Street, Dublin, 1, to whom applications for Fellowships should be forwarded The latest date for the receipt of applications is March 20, 1979 9786(E)

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
S.R.C. C.A.S E.
STUDENTSHIP

Applications are invited from graduates or those who will graduate in 1979 for an S.R.C C.A.S.E. Studentship held jointly between the Biology Department, Queen Elizabeth College, and the Centre for Overseas Pest Research, London. The project is concerned with host plant resistance to aphids and is specifically linked with Sorghum crops. Applicants should hold or expect to obtain at least an upper second class honours degree in a biological subject.

Further details can be obtained from Dr M Llewellyn, Biology Department, Queen Elizabeth College, Campden Hill Road, London W8 7AH.

9763(F)

UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE
POSTGRADUATE FELLOWSHIPS

Applications are invited from medical or dental graduates wishing to undertake work towards a higher degree, and from those already holding Ph.D. degrees, for Faculty of Medicine Fellowships tenable from October 1, 1979. The awards include a stipend of £4,250, the payment of University fees and assistance towards conference expenses.

Further details and application forms, which must be returned by March 16, 1979, may be obtained from the office of the Dean of the Faculty of Medicine, University of Edinburgh, The Medical School, Teviot Place, Edinburgh EH8 9AG.

9774(E)

FEBS FELLOWSHIPS

FEBS Fellowships are to support short-term (not longer than two month) visits by members of any FEBS Constituent Society to laboratories in another country in the FEBS area for the purpose of carrying out experiments with special techniques or other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

Fellowships will *not* be granted to attend courses, symposia, meetings or congresses.

Fellowships will cover both travel and subsistence.

Information and details of making an application may be obtained from:

Professor G. Dirheimer,
FEBS Fellowships Officers,
Institut de Biologie Moléculaire et Cellulaire du CNRS,
15 rue Descartes,
67084 Strasbourg Cedex,
France.

9754(E)

UNIVERSITY COLLEGE DUBLIN
DEPARTMENT OF HORTICULTURE
POSTDOCTORAL FELLOWSHIP

Applications are invited for a postdoctoral fellowship, sponsored by The National Board for Science and Technology, to study protein degradation and reutilisation in fruit trees and germinating seeds.

Applicants should have relevant research experience in the fields of horticulture, plant physiology or biochemistry.

The appointment will be for one year, initially, beginning as soon as possible. The starting salary will be £3,837 per annum on an incremental scale.

Applications giving details of qualifications and experience and the names and addresses of two referees should be sent to.

Dr M. J. Hennerty,
Department of Horticulture,
University College,
Glasnevin,
Dublin 9.

9782(E)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellow to work with Dr F. P Glasser on energy reduction in cement clinkering. A background in solid state or physical chemistry, ceramics, materials science or petrology-mineralogy would be advantageous

The post is supported by the Science Research Council for two years Starting date by arrangement within the period May–August 1979 Salary on Research and Analogous Staff IA Scale, £3,883 to £4,882, per annum, with appropriate placing

Further particulars from The Secretary, The University Aberdeen with whom applications (2 copies) should be lodged by March 16, 1979

9746(E)

UNIVERSITY OF BRADFORD
RESEARCH FELLOW IN VISUAL SCIENCE

Applications are invited for a 2 year Post-Doctoral Fellowship for research on the Characteristics of Normal and Defective Colour Vision. The successful candidate will be attached to the new Chair in Visual Science and will work under the direction of Professor J D. Moreland. It is hoped to make the appointment as soon as possible. Salary within range £3,883 to £6,555 p.a (under review) Superannuable. Further particulars and application forms (to be returned within 14 days of this advertisement) from the Registrar, Post Ref VS/RF/X, University of Bradford, BD7 1DP, West Yorkshire

9712(E)

UNIVERSITY OF CAMBRIDGE
POSTDOCTORAL RESEARCH FELLOWSHIP
IN THE DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE

A postdoctoral research fellow is required to investigate ordering and precipitation reactions in tungsten-based alloys, using primarily scanning/transmission electron microscopy and high-voltage electron microscopy The post will initially be for a period of two years commencing on October 1, 1979. The starting salary will be according to age and experience but is expected to be within the lower half of the "Agreed Scales" for a University Lecturer, at present £3,975 to £8,250 (under review), with full USS supplementation Applications including a curriculum vitae should reach The Secretary, University of Cambridge, Department of Metallurgy and Materials Science, Pembroke Street, Cambridge, CB2 3QZ, not later than March 16, 1979

9783(E)

COURSES

UNIVERSITY OF LEICESTER
M.Sc. IN EXPERIMENTAL SPACE PHYSICS

Applications are now being considered for the Space Physics course for entry in October. Candidates should have a degree with 1st and 2nd class honours in Physics, Mathematics or Engineering The course runs for 12 months and includes lectures, dissertation and project work covering both scientific (astronomy, earth sciences, applications) and technical (propulsion, orbits, communications, etc) aspects of present-day space research. A number of SRC studentships are available for successful applicants

Write for further details, including 2 academic referees, to Professor K A Pounds, Dept of Physics, University of Leicester, Leicester LE1 7RH.

9778(D)

M.Sc. in Medical Imaging Royal Free Hospital School of Medicine and Institute of Cancer Research (University of London). This is a new part-time course, lasting two calender years, commencing in October 1979, in which the formation, perception and analysis of images of biological structures will be considered, with particular reference to *in vivo* studies in medicine The course will be of particular value to persons working in hospitals or in employment with medical interests.

Applicants should normally have a First or Second Class Honours degree in physics, mathematics or a physical science.

Details of fees and application forms from: Professor H. A. B. Simons, Academic Department of Medical Physics, Royal Free Hospital, Pond Street, London NW3 2QG. 9767(D)

Ph.D. IN TOXICOLOGY

Applications are invited for a postgraduate course in Toxicology fo
which M.R.C postgraduate grants are available. Entrance requirement
are as for a normal Ph.D. The first year is a full-time course leading t
an M.Sc To give opportunities for further research training in toxicolog
the grants awarded for the M Sc will be extended for those student
showing satisfactory progress in the first year. These grants would be fo
three or four years in total as appropriate.

The Medical Research Council, the Royal Society and the Roy
College of Pathology have identified toxicology as a priority area fo
research training and therefore support the encouragement of first cla
students from a variety of disciplines to become involved in the scienc
of toxicology. In modern society contact with potentially toxic chemical
is increasing. Problems may arise from the use of drugs for medica
purposes, from occupational exposure to industrial products or inte
mediates and from environmental exposure to natural or syntheti
substances.

The postgraduate course in Toxicology, which was the first of its kin
in Europe, is organised by the Department of Biochemistry, University o
Surrey, with the M.R.C. Toxicology Unit, Carshalton, the Britis
Industrial Biological Research Association, Carshalton and Shell Tox
cology (Tunstall) Laboratory, Sittingbourne. During the course instructio
is given in these collaborative laboratories as well as at other majo
toxicological institutions.

The course is designed to provide graduates in science, and medical an
veterinary graduates, with an understanding and appreciation of the man
disciplines involved in toxicology Particular emphasis is placed on aspec
related to the biochemical mechanisms of chemically-induced toxicity, an
the assessment of toxicological hazard in the manufacture, use an
disposal of new chemical compounds, pesticides and medicines The cours
provides a broad biological education and is a suitable introduction fo
those intending to undertake research on the interaction of chemicals wit
biological systems.

The research period for the Ph.D. may be undertaken in one of th
above organisations or in other laboratories approved by the University
being suitable for toxicological research.

There are numerous interesting opportunities for scientists, educate
initially in different disciplines, who have acquired additional knowled
of toxicology. These may be in industry, government regulatory bodies,
research institutes with good career prospects in both laboratory work an
administration.

Further information and application forms to be returned by March 2
1979, may be obtained from·

Dr R. S. Jones,
Department of Biochemistry,
University of Surrey,
GUILDFORD,
Surrey GU2 5XH.

N. A. T. O.
ADVANCED STUDY INSTITUTE
on
"ESR and NMR of Paramagnetic Species i biological and related systems"

JUNE 3 to 15, 1979
ACQUAFREDDA DI MARATEA
150 km South of Naples, Italy

Closing date for applications: March 31, 1979

This A.S.I. will consist of a series of lectures accompanied by tutor
sessions. The object of the Course is that of reviewing the most rece
achievements in biological and related systems obtained by magnet
resonance techniques The A S I will represent a unique occasion f
chemists and biochemists to meet each other and to exchange th
experience and ideas. The Course will develop the Spin Hamiltoni
Formalism and will go through the theory of Spin Relaxation. The rece
developments on the instrument side will be shown and the princip
applications of magnetic resonance will be reviewed. The most releva
topics in the field of metalloenzymes, metalloproteins and of interactio
of nucleic acids with metal ions will be covered. On request of t
participants, microcourses will be held with the purpose to fill the g
in the theoretical foundations of the magnetic resonance experime

Lecturers: D Burton (Lund), P. F. Devaux (Paris), A. Ehrenbe
(Stockholm), J. F. Gibson (London), M Gueron (Palaiseau), W. De
Horrocks (Penn. State Univ.), N. A. Matwiyoff (Los Alamos),
McGarvey (Windsor), G Rotilio (Rome), R G Shulman (Bell Telephon
F Wehrli (Varian Zug), K. Wuthrich (Zurich) I. Bertini (Florenc
R S Drago (Urbana), Directors

A limited number of grants are available to participants from N.A T
countries They will cover about 50% of the living expenses and 'ab
25% of the travel expenses Living expenses are 276,000 Italian Li

Applications addressed to :

Prof. I. Bertini
Istituto di Chimica Generale della Facolta di Farmacia
Via G. Capponi 7
50121 FLORENCE, ITALY

may be made in the form of a letter giving a short curriculum vitae
present scientific interest.

THE UNIVERSITY OF LEEDS DEPARTMENT OF COMPUTER STUDIES

Persons interested in undertaking Research leading to M.Phil./Ph.D. in:—

— Computer Science
— Data Processing
— Numerical Computing
— Operational Research

are invited to contact

Dr D. H. Sleeman, Department of Computer Studies, The University, Leeds LS2 9JT, for further details

9789(D)

FEBS ADVANCED COURSES

No. 65. "The Control of Glycogen Metabolism"
Brussels, Belgium,
5-7 September 1979

The Course, organised by H. De Wulf, H. G. Hers, L. Hue and G. van de Werve, will cover the properties of enzymes involved in glycogen metabolism as well as aspects specific to muscle, liver, adipocytes and leucocytes. It will include lectures by invited speakers and presentation of posters by registered participants. A limited number of these posters will be subjected to general discussion. Registration fee: about $50. For further information, contact: Professor H. G. Hers, Université Catholique de Louvain and International Institute of Cellular and Molecular Pathology, UCL 75.39-75 avenue Hippocrate, B-1200 Brussels, Belgium. The deadline for applications and abstracts is **May 15, 1979.**

No. 57. "Recombinant DNA"
Zagreb, Yugoslavia,
15-27 October 1979

A Laboratory Course for 25 participants. The experimental program will include: In vitro recombination of DNA segments with plasmid and viral vectors; Cloning in *Escherichia coli* and *Bacillus subtilis;* Selection and screening of cloned recombinant DNA; Characterization of cloned recombinant DNA. Registration fee: $100. Applications **(by April 30, 1979)** and info: Dr Vjera Zgaga, Dept. of Experimental Biology and Medicine, "Ruder Boskovic" Institute, P.O.B. 1016, 41001 Zagreb, Yugoslavia.

No. 64. "Modern Methods of DNA Sequencing"
Gliwice, Poland,
5-10 November 1979

This Course for 15 students aims to disseminate within European research laboratories the two basic methods of DNA sequencing: the Maxam-Gilbert technique and Sanger's inhibitor chain-termination technique. Advanced studies will cover sequence organization of DNAs from various sources. Further information and application forms (to be returned **by May 31, 1979)** are available from the organizers: Dr M. Chorazy/Dr S. Szala, Dept. of Tumor Biology, Institute of Oncology, 44-100 Gliwice, Poland.

9753(D)

CHELSEA COLLEGE
University of London
POSTGRADUATE COURSE IN
HISTORY AND PHILOSOPHY OF SCIENCE

The Course is intended primarily for full-time students who are graduates in a physical or a biological science or in mathematics.

There are five constituent courses of lectures and tutorials running concurrently in the first year:

1. Mathematical Logic;
2. Philosophy of Natural Sciences;
3. History of Epistemology;
4. History of Natural Sciences;
5. Theory of Probability and Statistics (one term).

Students who have successfully completed this course may prepare a thesis under supervision with a view to obtaining the degree of M.Phil. or Ph.D.

POSTGRADUATE RESEARCH

Graduates suitably qualified in certain fields may proceed directly to a degree of M.Phil. or Ph.D. by research.

Further information and application forms from: The Secretary, Department of History and Philosophy of Science, Chelsea College, Manresa Rd, London SW3 6LX (Tel: 01-352 6421).

9805(D)

STUDENTSHIPS

UMIST
S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited for a C.A.S.E. Studentship financed by S.R.C. in collaboration with Shell Biosciences Laboratory, Sittingbourne, tenable for three years, for a study of the effects of high pressure/temperature enviornments on the physiology, biochemistry and corrosive properties of sulphate-reducing bacteria using already developed culture systems.

The study would be of particular interest to those with a background in microbiology, applied biology or biochemical engineering, though candidates with other qualifications will be considered.

A number of C.A.S.E. awards in other areas of corrosion science are also expected to be available and general applications will be considered.

Applicants should send curriculum vitae and names and addresses of two referees to Professor G. C. Wood, Corrosion and Protection Centre, UMIST. Manchester M60 1QD.

9788(F)

UNIVERSITY OF EAST ANGLIA
SCHOOL OF BIOLOGICAL SCIENCES
POSTGRADUATE STUDENTSHIPS

Applications are invited for the following Science Research Council-funded studentships:

1. 'A study of mutational processes in myxobacteria': supervisor Dr C. H. Clarke
   or
   'The role of asparagine in the nitrogen metabolism of plants': supervisor Dr A. P. Sims.
2. 'Molecular enzymology of terminal respiratory proteins in bacteria and/or mammals': supervisor Dr C. Greenwood.
3. 'Transport processes in artificial bilayer lipid membranes': supervisor Dr E. J. A. Lea
   or
   'Transport processes in plant leaves': supervisor Dr J. F. Thain.
4. 'Resource partitioning among the fish populations in a Norfolk Broad': supervisor Dr C. R. Townsend.
5. 'Microtube function in cell formation, division and movement in *Drosophila* embryos'; supervisor Dr R. M. Warn.

Applicants should posses, or expect to obtain a First or Upper Second Class degree and should write to Professor A. F. G. Dixon, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ, enclosing a curriculum vitae and the names of two referees.

9730(F)

S.R.C. C.A.S.E. RESEARCH STUDENTSHIP
UNIVERSITY OF NEWCASTLE UPON TYNE
SCHOOL OF PHYSICS

Applications are invited from persons holding, or expecting to obtain, a good honours degree in physics for a C.A.S.E. studentship in theoretical solid state physics concerning electronic properties of defects in semiconductors, in collaboration with the Royal Signals and Radar Establishment, Malvern.

Further details are available from Dr M. Jaros, School of Physics, The University, Newcastle upon Tyne, NE1 7RU, to whom applications should be sent along with curriculum vitae and the names of two referees.

9729(F)

ASSISTANTSHIPS

UNIVERSITY OF OXFORD
DYSON PERRINS LABORATORY
POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship supported by the S.R.C. to further develop and exploit a new method for measuring kinetic isotope effects (including those for 'heavy' atoms) with high accuracy. Preference will be given to candidates with experience in kinetics or in synthesis with stable isotopes.

The appointment is for two years, commencing October 1, 1979, or at an agreed date. The salary will be on the Research Support Grade Scale 1A, initially not higher than £4,130 p.a. (under review), plus U.S.S. benefits.

Applications (one copy), with curriculum vitae and the names and addresses of at least two referees (overseas applicants should ask referees to write directly to the address below) should be sent not later than March 31, 1979, to Dr M. J. T. Robinson, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, from whom further information may be obtained.

9801(P)

THE EAST OF SCOTLAND COLLEGE OF AGRICULTURE

Applications are invited for a

RESEARCH ASSISTANTSHIP

tenable for a period of 18 months from March 1979, to be employed in research on certain storage diseases of potato tubers, principally dry rot.

Candidates should have a good honours degree in Biology, Botany or Agricultural Botany, preferably with some experience in plant pathology.

The work will be carried out in the Plant Pathology Department under the supervision of Dr A. E. W Boyd.

Salary: £3,384 per annum.

Further particulars and application form from The Secretary, The East of Scotland College of Agriculture, West Mains Road, Edinburgh EH9 3JG.

Closing date for applications: March 8, 1979.

9768(D)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY
TWO POSTDOCTORAL RESEARCH ASSISTANTSHIPS
required

1. Bio-physical chemist to join research group working on membrane structure and function. Experience of spectroscopic and surface techniques a particular advantage.
2. Chemist with either materials science or surface coating experience to join research group working on new biomaterials.

Initial salary for both appointments within range £3,909 to £4,655 plus £450 London Allowance. Further particulars available from the School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP, or telephone 01-837 5385 ext. 54. Closing date March 9, 1979.

9597(P)

AWARDS

CHELSEA COLLEGE
University of London
PHARMACY DEPARTMENT
S.R.C. C.A.S.E. AWARD

Applications are invited from graduates of chemistry, engineering (chemical or mechanical), pharmacy or physics with a first or upper second class honours degree, or undergraduates who expect to graduate in 1979, for an S.R.C. C.A.S.E. award tenable in the Pharmacy Department of Chelsea College University of London. The project involves a study of the factors involved in the processing of materials for the manufacture of a novel dosage form or drugs and will be closely associated with the industrial sponsor. For further details and application forms contact the academic supervisor, Professor J. M. Newton, Pharmacy Department, Chelsea College, University of London, Manresa Road, London SW3 6LX.

LECTURES

N.A.T.O. ADVANCED STUDY INSTITUTE

sponsored also by

The Greek National Committee for Astronomy

on

GALACTIC X-RAY SOURCES

May 28 to June 9, 1979

AT CAPE SOUNION, GREECE

The topic of Galactic X-Ray Sources is currently of great interest to astronomers and physicists. There are numerous unsolved questions associated with the existence and behaviour of these X-Ray sources that challenge both observational and theoretical aspects of astrophysics. The Institute is designed to bring together scientists from many subdisciplines to weigh, evaluate and consider these problems.

The Lecturers will include:

J. Cassinelli (U.S.A.)
L. Culhane (U.K.)
A. Cowley (U.S.A.)
A. Dupree (U.S.A.)
H. Gursky (U.S.A.)
J. Hutchings (Canada)
S. Ilovaisky (France)
B. Margon (U.S.A.)
R. McCray (U.S.A.)
J. Trumper (Germany)
E. Van den Heuvel (Holland)
M. Watson (U.K.)

Method of application: Applicants for the Institute should be active research workers at or about the postdoctoral level. The application should include a statement of interest and potential contribution to the Institute.

A limited number of N.A.T.O. Grants for partial support of participants are available.

Applications must be submitted as soon as possible to:

P. W. Sanford (Conference Director)
Mullard Space Science Laboratory
University College London
Holmbury St. Mary
Dorking, Surrey, U.K.

The Advisory Committee consists of P. Laskarides (Athens—Local Organiser), A. Dupree (U.S.A.), J. Hutchings (Canada).

The detailed scientific programme will be defined in early April.

Travel arrangements are through American Express, Travel Division, Place Rogier, 24—1000 Brussels, Belgium.

CONFERENCES

A Major International Conference

AUTOMATION IN INDUSTRIAL AND CLINICAL CHEMISTRY

16 – 18 July, 1979

The City University, Northampton Square, London EC1

Workers in clinical, industrial and academic environments will find this conference of particular value as it has been designed to provide a cross-fertilization of the ideas and concepts of automation between the three sectors.

KEYNOTE SPEAKERS

Professor M Bonner Denton, The University of Arizona, USA.
Dr F L Mitchell, Clinical Research Centre, Harrow, Middlesex, UK.
Dr R W Arndt, Mettler Instrumente AG, Greifensee, Switzerland.

Some of the papers included in the programme:

Training of clinical laboratory personnel in the use and maintenance of automatic systems, **Dr L B Roberts**, Gartnavel General Hospital, UK.

An experiment in education for automatic analysis: the 1979 Chemical Society Summer School, **Dr D Betteridge**, University College of Swansea, UK.

Recent developments in flow injection analysis, **Dr J Ruzicka**, The Technical University of Denmark, Lyngby, Denmark.

DACOS – a new approach to kinetic analysis, **M Snook**, Clinical Research Centre, Harrow, Middlesex, UK.

Recent developments in automatic chromatography, **Dr P B Stockwell**, The Laboratory of the Government Chemist, London, UK.

The cost benefits of automated analytical systems, **J G Jones**, Wessex Water Authority, UK.

Economic techniques for evaluating automation alternatives, **T M Craig**, E I Du Pont de Nemours & Co, Wilmington, Delaware, USA.

Automation of radioimmunoassay and related analytical techniques, **Professor J Landon**, St Bartholomew's Hospital, London, UK.

Industrial applications of automation with particular reference to the InfraAlyzer, **Dr H Swann**, University of Nottingham, School of Agriculture, UK.

Extraction in continuous flow systems with examples from pharmaceutical analysis, **Dr B Karlberg**, Astra Pharmaceuticals AB, Sodertalje, Sweden.

Improved accuracy in automated chemistry through the use of reference materials, **Dr R F Coleman**, National Physical Laboratory, Teddington, UK.

The symposium fee will be £130 inc. VAT and this fee will include: a) documentation and abstracts of all papers; b) luncheon, tea, coffee etc. To register for this symposium and obtain further details fill in the coupon below.

I/We wish to register for the symposium and enclose my/our cheque for £ ....

Consulting Services
TO OVERSEAS PURCHASERS OF U.S. MEDICAL-SCIENTIFIC INSTRUMENTATION:

We are a private professional consulting group composed of scientists and physicians in academic research, service laboratories, and hospitals with ten years of international (WHO) experience. If you intend to purchase instrumentation or equipment and have questions as to optimum suitability for your needs, comparative product advantages, reliability and service, or simply wish to know the best way to proceed given your requirements, we can be of considerable assistance . . . in basic science or clinical medicine.

LIQUID SCINTILLATION CHEMICALS

We're at Your Service More Than Ever Before.

Our sales, service, and technical assistance have never been stronger in Europe. As a result you can expect immediate response from the NEN office in your country, and fast delivery of the products you need from the world's most widely referenced selection of liquid scintillation chemicals.

If you need technical assistance, you will find that our people are exceptionally well equipped to provide it. But if they don't have the answer, the director of our LSC Applications Laboratory, Dr. Yutaka Kobayashi, will help you.

In short, we're doing everything to meet the rapidly increasing demand for NEN liquid scintillation chemicals in Europe—with an expanded technical sales force, locally available products, and fast response to technical questions.

We look forward to your call.
